An Address
ON THE
FUNCTIONS OF THE SCHOOL CLINIC.

Given at the Opening of the New School Clinic at Birmingham on Sept. 30th, 1926,

BY SIR HUMPHRY ROLLESTON, BART., K.C.B., M.D. CAMB., F.R.C.P. LOND.,
REGIUS PROFESSOR OF PHYSIC, UNIVERSITY OF CAMBRIDGE.

THE privilege of assisting at the opening of the new and much expanded School Clinic in Sheep-street naturally arouses satisfaction at a further step in this progressive city towards the realisation of the ideal of the science and art of medicine—namely, the prevention rather than the cure of disease. Although long recognised in theory, the systematic practice on a large scale of preventive medicine is of comparatively recent growth, and much remains to be done—for example, the prophylaxis of the rheumatic conditions which are responsible for so much crippling and mortality from heart disease among children. This very important subject has naturally received attention from the Ministry of Health, with the result that special lines of action have been recommended and that many school medical officers made particular investigations into the subject in 1924 (vide Report No. 23, The Incidence of Rheumatic Diseases). The Birmingham Educational Committee have been foremost in the initiation of measures for the relief and care of rheumatic, cardiac, and choreic children.

The earlier in the life of the individual that hygienic measures and protection from infection are instituted, the better the prospect of health; preventive medicine is most successful in infancy and childhood, and in Sir Leslie Mackenzie's words "the health of the child is wealth to the nation." It has been estimated that 90 per cent. of infants are born healthy and normal, but some years ago Dr. L. D. Cruickshank concluded that at least 42·5 per cent. of children in Scotland entering school suffered from forms of disease largely preventable, and that in addition 70 per cent. of the children examined suffered from defective teeth; among 262,482 children in elementary schools in London 69·5 per cent. were in 1925 found to require medical or dental treatment, as compared with 82 per cent. in 1915. The Birmingham Clinic Centre makes ample provision for dental inspection and treatment by six full-time and five half-time dentists and one assistant school dentist; in the year ended Dec. 31st, 1925, 105,104 children were inspected; 74,736, or 71 per cent., were found to require treatment, and of these latter 32,257, or 43 per cent., were treated dentally. These figures show the need of systematic inspection and care of children in the pre-school period and justify the criticism that to start inspection only during the school period would be to begin too late; but though an enormous amount has been and is being done by infant and child welfare centres, the conditions make it difficult to carry this out in the same systematic and universal manner as school inspection; school inspection and treatment therefore constitute an efficient and most necessary means of preventing progressive disability.

HISTORY OF SCHOOL CLINICS.

In 1904 the Inter-Departmental Committee on Physical Deterioration recommended that a systematised medical inspection of school-children should be imposed on every school authority, and in the following year some degree of medical inspection was voluntarily established in 48 educational centres. In 1907 medical inspection of children attending public elementary schools was made obligatory on all local education authorities under Section 13 (1) *b* of the Education (Administrative Provisions) Act, and these authorities were empowered, with the sanction of the Board of Education, to make arrangements for attending to the health and physical condition of the children, the cost being then mainly borne by the rates. Under this power arrangements were accordingly made for the medical treatment of school-children by various agencies, such as private practitioners, hospitals, and dispensaries. By circulars and other means the Board of Education pointed out the value of school clinics, and thus the more enterprising authorities were led to establish them. The first dental clinic for school-children was opened in 1907 at Cambridge, where the local education authority made the arrangements for the dental inspection, and the cost of the clinic was undertaken by a private individual. Bradford, in 1908, submitted to the Board of Education the first scheme for a school clinic, the arrangements including provision for the treatment of minor ailments—ringworm, discharging ears, the testing of eyesight, and prescriptions for spectacles. The number of such clinics gradually increased until there were 57 in April, 1912, when the Board of Education then for the first time issued regulations sanctioning grants-in-aid of medical treatment, the total amount of the grant made by the Board of Education for the year ending March 31st, 1913, being limited to £60,000; in 1913–14 the grant was made for inspection in addition to treatment, and in 1923–24 the Board allowed a grant up to £600,000 for the purposes of inspection and treatment. The local education authorities were thus enabled progressively to increase their arrangements for treatment by clinics and in other ways, and there are now more than 1395 clinics provided by 312 out of the entire 317 local education authorities. Further, Section 80 (2) of the Education Act, 1921, laid upon the local education authorities for higher education the duty of providing medical inspection of children immediately before, or at the time of, or as soon as possible after, their admission to certain secondary schools and other institutions, and on such other occasions as the Minister of Health may direct. The local education authorities were also empowered to make such arrangements as may be sanctioned by the Minister of Health for attendance of the health and physical condition of such children and young persons.

This progressive expansion, which there is every reason to anticipate will continue, renders the school clinic system correspondingly more essential as an integral part of the health services of the nation. That it meets a widely felt need is shown by its popularity among the mothers of school-children. The total gross cost of the school medical services amounted in 1923–24 to £1,220,268, or only about one-fiftieth of the total sum spent on public elementary education—a very small premium for rendering education a useful asset and for improving the physical and financial well-being of the nation. The correlation of education and hygiene, or of the mental and physiological righteousness of the rising generation, is due in a degree not adequately recognised by the public—medical or lay—to the Chief Medical Officer both of the Ministry of Health and of the Board of Education, Sir George Newman.

WORK OF THE SCHOOL CLINIC.

(1) Inspection of school-children must be regarded as a most important element in preventive medicine; for the beginnings of disease, often due to environmental influences or to dietetic errors, can be detected and corrected by the following-up undertaken by nurses and the voluntary services of care committees and social workers. Thus the inspection of children in a clinic, where the conditions are so much more favourable for satisfactory diagnosis than in those of the school-room, renders it a health centre from which radiate the principles of preventive hygiene. Parents, who are erroneously inclined to undervalue inspection as compared with treatment, thereby come to realise their responsibilities to their children—for example, last year Birmingham parents were instructed at the clinic with regard to verminous infestation. The school-children, too, partly unconsciously, from the force of example and from the silent influence of their

surroundings in the school and the clinic, become impressed with the necessity of personal hygiene. Children who are dull, backward, or fail to come up to the standard can be investigated in the clinic in order to determine the cause, such as mental deficiency or physical defect, ocular or adenoid lesions, overgrowth, evil environment, or overstrain. The prophylactic value of inspection may be illustrated by the detection of adenoids, enlarged tonsils, and bad teeth which, besides impairing the mental and bodily efficiency, are responsible for a large proportion of the cases of rheumatic heart disease and probably for nine-tenths of the cases of ear disease in children. Reinspection of children who have undergone treatment is conveniently carried out at the school clinics. In 1925 the number of school-children medically inspected in Birmingham was 48,471, and of these 32,257 were found to have dental defects, and 1461 were operated upon for tonsils and adenoids. These figures emphasise the importance of a thoroughly up-to-date equipment for the school clinic.

(2) As a treatment centre, to supplement, not to take the place of, the existing facilities in the area, it provides for the relief of minor ailments and injuries usually requiring daily treatment by nurses under a doctor's direction. This work can be done more expeditiously in a school clinic *ad hoc* than in a hospital out-patient department or surgery crowded with adults suffering from very various diseases. In addition specialist treatment not otherwise locally available, such as of the throat, ear, nose, and eye disease, the X ray treatment of ringworm, and dental conditions, is given; remedial exercises, such as form an important factor in orthopædic treatment, are also available.

(3) The clinic is a centre for research based on observations made during routine work; there is much scope for the study of the conditions and symptoms leading up to disease, and in this way preventive medicine can be much advanced. That the ample material and opportunities for such work have been utilised is proved by what has been accomplished since 1908. Sir George Newman's annual reports on the Health of the School Child bear witness to the numerous individual inquiries which have been carried out, and further advantage will accrue from the special committees set up to investigate the prevention of enlarged tonsils and adenoids, the causation of defective vision, anthropometry, and the problems associated with mental deficiency. The 550 special schools in the country for mentally and physically defective children, which accommodate 45,000 children, offer fields for investigation, and these have not been neglected in Birmingham, which has been so active in the study of mental disease under the leadership of the late Sir Frederick Mott. The ultimate value of education for the mentally defective has been most patiently investigated by Marion Bridie and many others.

(4) The school clinic should serve as the administrative and organising centre of the School Medical Service; in addition it coördinates inspection with treatment and treatment with reinspection and following-up. Thus failure of a child to attend at the clinic is easily detected and efficient steps can then be taken to remedy the default. Records can conveniently be stored there under the supervision of clerks, and registration carried out and statistics worked up. During the year 1925 no less than 34,896 reinspections were made at the Birmingham School Clinic. The clinic also provides opportunities for teamwork by the teacher, medical man, and the parents on behalf of the children's welfare.

STAFFING OF THE SCHOOL CLINICS.

The future and continued success of the school clinic and other public medical services necessarily depends on the attitude of the medical profession, and this in its turn is affected by the training of the medical student, the capacity and resource of the medical practitioner, and the opportunity for the medical practitioner to make his contribution to the public medical services either as a part-time or whole-time officer. There is some m sapprehension in the criticism occasionally made that the Government desires to have a State medical service in which all medical practitioners shall be enrolled. There is, of course, already a State medical service. But it has never been seriously proposed that all medical men should become whole-time civil servants. Indeed, provision has been made for securing the advice and assistance of medical practitioners within their compass and opportunity. That they are not eliminated is obvious from the facts recorded by Sir George Newman, that any private practitioner may enter or not as he pleases the health insurance service, that with few exceptions all the 1770 certifying factory surgeons are private practitioners, that many assist as time and inclination determine both the school medical service and the public health service (most medical officers of health are also private practitioners), and that of the 1800 or more medical men and women engaged by local education authorities in the inspection and treatment of school-children 1023 are in private practice and 821 are whole-time; indeed, it is essential that private practitioners should take their full share in the work of the school clinics, so that they may have more opportunities for detecting the early signs of disease, to become active agents in the prevention of disease, and workers for the collective rather than only for the individual good; it is therefore arranged that in the first instance cases requiring treatment should be sent to the family doctor. For 140 education areas there are 289 women doctors or dentists, and no doubt the advantages of the service will appeal in an increasing degree to women doctors. The nurses employed number 4520, and their actual functions in the school and clinic may also usefully be combined, especially in rural districts, with those of a health visitor. This nurse health visitor looks after the care and welfare of the children of school age and correlates this work with other departments of public health.

PRESENTATION TO A MEDICAL MAN.—On the completion of 21 years' service Dr. Benjamin Holroyd Slater, of Bradford, Yorks, medical superintendent of the St. Luke's Hospital, Bradford, was on Sept. 23rd presented with a silver tea service from the hospital staff. Dr. Slater said that in the old days the fact that the hospital was a Poor-law hospital acted as an extraordinary deterrent to people entering. The municipalisation of the hospital by the corporation in 1920 had wrought a great change.. It was stated that the work of the hospital had practically doubled since its municipalisation. Last year there were 7050 admissions, 485 births, and operations 2018.

DONATIONS AND BEQUESTS.—Mr. James Albert Fleming, of St. James's-court, S.W., and of Entre Rios, Argentine Republic, bequeathed the following legacies: £1000 each to the Halifax Royal Infirmary, Dr. Barnardo's Homes, and the Royal National Lifeboat Institution.—Mr. J. T. Jackson, formerly of Ilkley and Whitby and now of Jersey, has given £1000 to the Yorkshire Cancer Campaign.—Mr. Thomas Martin, of Pollokshields, Glasgow, who left £19,576, made, among others, the following charitable bequests: £2100 to the Royal Hospital for Sick Children, Glasgow, to endow two cots; £1000 to the Glasgow Royal Cancer Hospital to be used especially for research; £1000 to endow a cot in the Biggart Hospital Home, Prestwick; £500 for the Glasgow Poor Children's Fresh-Air Fortnight and Cripple Children's League; £1000 to the West Highland Cottage Hospital, Oban. The residue to be divided between East Park Homes for Infirm Children, the Maternity Hospital, and the Samaritan Hospital, Glasgow.

An Address
ON THE
FUNCTIONS OF THE BILIARY PASSAGES IN RELATION TO THEIR PATHOLOGY.

Delivered at the Institute of Pathology and Research, St. Mary's Hospital.

BY D. P. D. WILKIE, M.CH. EDIN., F.R.C.S. ENG.,
PROFESSOR OF SURGERY, UNIVERSITY OF EDINBURGH.

(WITH COLOURED PLATE.)

THE frequency of pathological changes in the extra-hepatic bile passages, the amount of disability and suffering to which they give rise, and the large share of the surgeon's time and energy which is devoted to their treatment, invest the subject of the earliest changes from normal function to disease in this region with a peculiar interest and importance. In this, as in other fields of medicine, we advance from the treatment of the grosser forms and full-blown stages of disease to the earlier, less well-defined, and subtler changes, and thus we reach a region where a clear distinction between the normal and the first shades of the pathological needs acute perception and unbiased observation. More and more necessary becomes a knowledge of the normal structure and function of the parts with which we deal, and the surgeon of to-day requires with ever-increasing reason a knowledge of minute anatomy and of physiology. I do not hesitate, therefore, to put before you some facts regarding the anatomy and physiology of the biliary tract which throw light on the morbid conditions with which we meet in the surgery of this region.

ANATOMY.

The gall-bladder averages 9 cm. in length and has a capacity of 50 c.cm. For purposes of description it is divided into several parts—fundus, body, infundibulum, neck, and cystic duct. It possesses a muscular coat which, in the fundus and body, is arranged in a fasciculated net-like manner as in the urinary bladder, but in the infundibulum and the neck in more definite outer longitudinal and inner circular coats. In the neck the circular coat is well developed so as to suggest sphincteric function (Fig. 3, on plate). In the cystic duct the muscular coat is very deficient, especially in the distal part of the duct, and it is represented merely by some irregularly disposed longitudinal and oblique bundles. On the other hand, the fibrous tissue and elastic fibres found throughout the wall of the gall-bladder are specially developed in the wall of the cystic duct. The mucous membrane of the gall-bladder, which is disposed in delicate, closely interwoven folds, has practically no glands. In place of them are found the Luschka crypts which penetrate into the muscularis. The columnar epithelial cells give but a faint reaction for mucus but contain almost invariably granules of bile-pigment. In the neck we find the first of the Heisterian folds which extend down into the proximal part of the cystic duct. These folds are formed by an inward projection of the circular muscular coat. The distal part of the cystic duct has the same structure as the hepatic and common ducts—namely, a wall built up almost entirely of connective tissue and elastic fibres with practically no smooth muscle, and a mucosa rich in specific glands.

The blood-supply of the gall-bladder is unusually free for the size of the organ, and the lymph drainage is remarkable for the number of vessels ramifying in the submucous and subperitoneal coats. The main channels drain through the cystic gland and the glands lying along the common bile-duct, and there anastomose with the lymphatics from the head of the pancreas. The gall-bladder and ducts are generously supplied with nerve-fibres, both from the vagus and sympathetic. Through the latter, by way of the hepatic and phrenic plexuses, it is connected up with the phrenic nerve, thus accounting for the shoulder tip pain experienced in some cases of biliary colic. In the wall of the cystic duct nerve-fibres and ganglion cells are especially numerous, a point of some significance in pathological conditions.

Around the lower end of the common bile-duct is an arrangement of well-developed muscular fibres. These encircle the lower 2 cm. of duct and have been proved to have a definite sphincteric function (sphincter of Oddi). This part of the duct may be subdivided into two portions—the *pars duodenalis*, as the duct passes obliquely through the duodenal wall, and the *papilla*, which projects into the lumen of the duodenum. Whilst both portions are enclosed in muscle-fibres, sphincteric in function, it has been shown that they may act independently and each has a distinct nerve-supply. The sphincter of Oddi will withstand a pressure of 150 mm. of water and, as Archibald has shown, when stimulated by the introduction of hydrochloric acid into the duodenum, will resist pressure up to even 800 mm. of water. Animals possessing no gall-bladder show anatomically a similar sphincteric arrangement, but this will not resist a pressure of more than 30 mm. of water and is probably non-functioning.

Normally the flow of bile into the duodenum is intermittent. The sphincter of Oddi remains in a state of mild tonic contraction and only relaxes to allow the egress of bile under stimulation, usually that of food entering the duodenum. The introduction of peptone or a strong solution of magnesium sulphate into the duodenum leads to a relaxation of the sphincter and a flow of bile. Thus by the Meltzer-Lyon test, we may determine the presence of infection in the biliary passages and less certainly the functional activity of the gall-bladder.

NERVE CONTROL OF THE BILIARY PASSAGES.

The outcome of many experimental researches on this subject may be stated briefly as follows.

(1) Slight stimulation of the vagus causes contraction of the gall-bladder with a relaxation of the sphincter of Oddi.

(2) Strong stimulation of the vagus causes a firmer contraction of the gall-bladder, *especially the neck*, and a spasm of the sphincter of Oddi.

(3) Stimulation of the sympathetic causes a relaxation of the gall-bladder and ducts, and a contraction of the sphincter.

(4) The effect of strong vagus stimulation can be counteracted by an intravenous dose of atropine and augmented by pilocarpine.

The foregoing facts would seem to indicate some not unimportant function for the gall-bladder, and a study of its contents under varying conditions confirms this view.

FUNCTIONS OF THE GALL-BLADDER.

That the gall-bladder is not essential to healthy life is proved by the fact that in some animals—e.g., the deer, the horse, and the rat—it is absent, and also by the large number of human beings whose gall-bladders have been excised, and who thereafter have enjoyed apparently normal health. The fact that its absence can be tolerated is, however, no argument against the importance of its function; it is merely a tribute to Nature's powers of compensation. The gall-bladder has by various observers been regarded (*a*) as a regulator of pressure in the biliary duct system, (*b*) as a secretory organ adding mucus and possibly cholesterin to the bile, and (*c*) as a concentrator and storage cistern for the bile in fasting periods. Probably it subserves all these functions in greater or less degree.

Hamarsten showed that the chemical compositions of hepatic and gall-bladder bile differed markedly, the latter showing a concentration of eight times the former. The experiments of Rous and MacMaster on the bile-pigment content demonstrated that within the gall-bladder the hepatic bile is concentrated ten times. So active is this concentrating function, that

624029

when the gall-bladder is drained with a tube, the bile in its passage through the gall-bladder to the tube is concentrated two to three times. Hence it is that an organ with a capacity of but 50 c.cm. can store the bile from the liver amounting to 800–1400 c.cm. per diem. These observations have received a further confirmation from the clinical side by the method of cholecystography—a method which depends for its success on the remarkable concentrating power of the gall-bladder. The concentration of the bile and its contained opaque salt, sodium-tetra-iodo-phenol-phthalein, in the functioning gall-bladder causes a dense shadow of this organ to be cast whilst the ducts containing the unconcentrated bile transmit the X rays.

The resorption, mainly of water and salts, occurs principally by the lymphatics and blood-vessels, which must certainly be helped by the rhythmic contractions of the gall-bladder, recorded by numerous observers, and probably also by the respiratory movements. Such resorption explains the presence of droplets of lipoid within the cells of the mucosa (as Aschoff has pointed out, this so-called "resorption fatty change," giving a typical sulphur-yellow spotting to the wall, occurs only in the true gall-bladder and never in the cystic duct). The gall-bladder adds a certain amount of mucus to the bile and secretes mucus freely when inflamed. It should be pointed out, however, that ligature of the cystic duct does not lead to a mucocele of the normal gall-bladder which, on the contrary, contracts on a jelly-like inspissated residue of the bile contained within it at the time of ligature.

Bollman, Mann, and De Page have shown by experiment that a cholecystitis diminishes markedly the concentrating powers of the gall-bladder, this loss of function being in direct proportion to the intensity of the cholecystitis. It is of interest to note that in the rat, which has no gall-bladder, the liver bile contains eight times more pigment than the liver bile of the mouse which has a gall-bladder (MacMaster). Under normal conditions it is almost certain that the gall-bladder never empties more than a relatively small part of its content. Auster and Crohn injected carmine powder into the gall-bladders of animals and found that it took practically a week for it to be evacuated. At operations in the upper abdomen, under all conceivable conditions as regards relation to food ingestion, I have but once encountered an empty gall-bladder. This was an instance of the one condition which apparently can give rise to such a collapsed and empty gall-bladder —namely, a tumour involving both hepatic ducts at their junction to form the common duct (Fig. 4, on plate). Some observers maintain that normally the gall-bladder secretes cholesterin. Naunyn has upheld this view and the observations of Sweet, who found that after cholecystectomy the cholesterol content of the blood was increased and did not reach normal for 40 days, would appear to support it.

FUNCTIONS OF THE BILE-DUCTS.

The bile-ducts have a directly opposite function to the gall-bladder. From the glands in the mucosa a watery fluid is secreted which dilutes the bile. This fluid can be secreted under a tension much above that at which the liver can secrete bile. If the common duct be obstructed and the pressure-regulating function of the gall-bladder be wanting, either from disease or previous operation, the secretion from the glands in the duct-walls will gradually replace the bile which is absorbed and the whole biliary duct system will eventually fill with a colourless fluid, the so-called "white bile." There is no more remarkable experience in surgery than to find in the deeply jaundiced patient, whose every tissue appears impregnated with bile-pigment, the bile-ducts distended with a limpid fluid containing no trace of either bile-pigments or salts (Fig. 5, on plate). The absence of bile in ducts is not due to failure of liver cells to function, as in these cases there is usually a free discharge of bile from the duct within a few hours of drainage being established. The cystic duct appears to have the same functions as the other ducts, to which it belongs rather than to the gall-bladder.

If in an animal such as the cat, the common duct be ligated below the entrance of the cystic duct and at the same time the left hepatic duct be ligated, we have two closed systems of ducts, the one draining the right lobe of the liver and in direct communication with the gall-bladder; the other draining the left lobe of the liver but having no communication with the gall-bladder. If the animal be killed five or six days later the right duct system is seen to be distended with dark-green bile; the left duct system is filled with clear fluid—i.e., with "white bile" (Fig. 1, coloured plate). Rous and MacMaster, who first carried out this experiment, thus proved afresh the great capacity of the gall-bladder for concentrating bile and so relieving the pressure on the liver. There are limits, however, to this concentrating and pressure-relieving capacity and, contrary to the usual experience in this matter, I have found that after ligation of the common bile-duct in the cat the whole biliary system, including the previously healthy gall-bladder, may be found distended with "white bile" (Fig. 2, coloured plate).

EFFECT OF REMOVAL OF THE GALL-BLADDER.

Cholecystectomy is usually followed by a primary biliary incontinence and later by a dilatation of the bile-ducts, sometimes with dilatation of the stump of the cystic duct to form a new miniature gall-bladder. There is later a return of intermittent discharge of bile into the duodenum. In some cases, however, incontinence of bile persists and the bile-ducts do not dilate.

In view of the rich distribution of nerve-fibres and ganglion cells in the wall of the cystic duct, it is a matter of some practical interest to know whether a total or partial removal of the cystic duct influences the tonicity of the sphincter of Oddi and the presence or absence of common duct dilatation after operation.

Clinically, we find every now and then that a patient after cholecystectomy will within a short period have a return of pains not unlike those previously present, possibly also with a transient icteric tinge of the skin. The presence of an overlooked stone in the common duct is naturally suspected, but at a second operation nothing may be found but a dilated common duct. Here we must presume a persistence of spasm of the sphincter of Oddi even after the removal of the main focus of irritation.

In considering the pathology of the biliary passages I shall confine myself to some aspects of the origin of gall-stones and to the subject of biliary stasis.

METABOLIC GALL-STONES.

The Single Radiate Cholesterin Stone.

We owe to Aschoff and Bacmeister the conception of stone formation in the gall-bladder as the result of some dysfunction in cholesterin metabolism and excretion, in the absence of any infection of the bile passages. Contrary to the teaching of Naunyn that a "stone-forming catarrh of the vesical mucous membrane" is the essential antecedent to stone formation, Aschoff has built up a strong case for the single aseptic gall-stone. This stone has the following characteristics: (1) It is in composition practically pure cholesterin, although its central part may be stained with bile-pigment. (2) It is of coarsely crystalline structure. It shows no lamellation, but radiating and intertwining coarse cholesterin columns. (3) It is always single and has been designated the "cholesterin solitaire" or monolith. (Not infrequently other stones may form in the same gall-bladder, but these differ in structure.) (4) It is frequently found in a gall-bladder showing no trace of inflammation. (5) It may be present without symptoms.

Cholesterin is a normal constituent of the bile. It is held in colloid solution determined largely by the presence of the bile acids, and, as Rosin has shown, not only by the amount of bile acids, but by the

FIG. I.

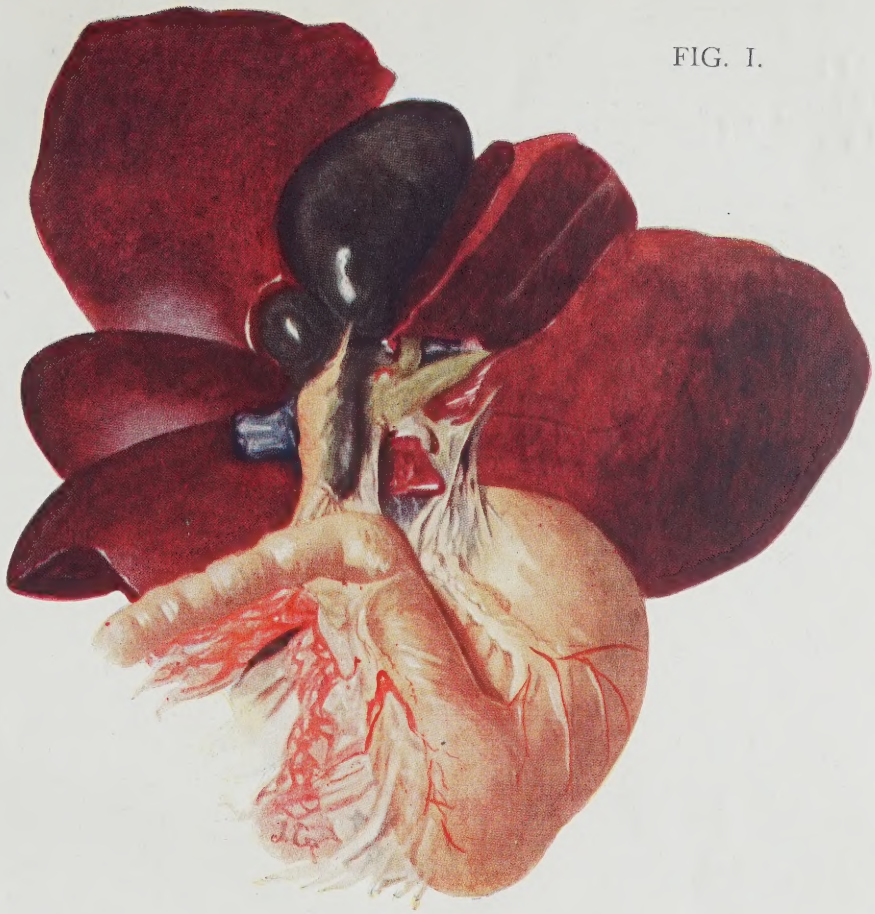

FIG. I.—Condition of biliary passages one week after ligature of common bile-duct and left hepatic duct. Dark green bile on right side, "white bile" on left. (Experiment of Rous and MacMaster.)

FIG. II.

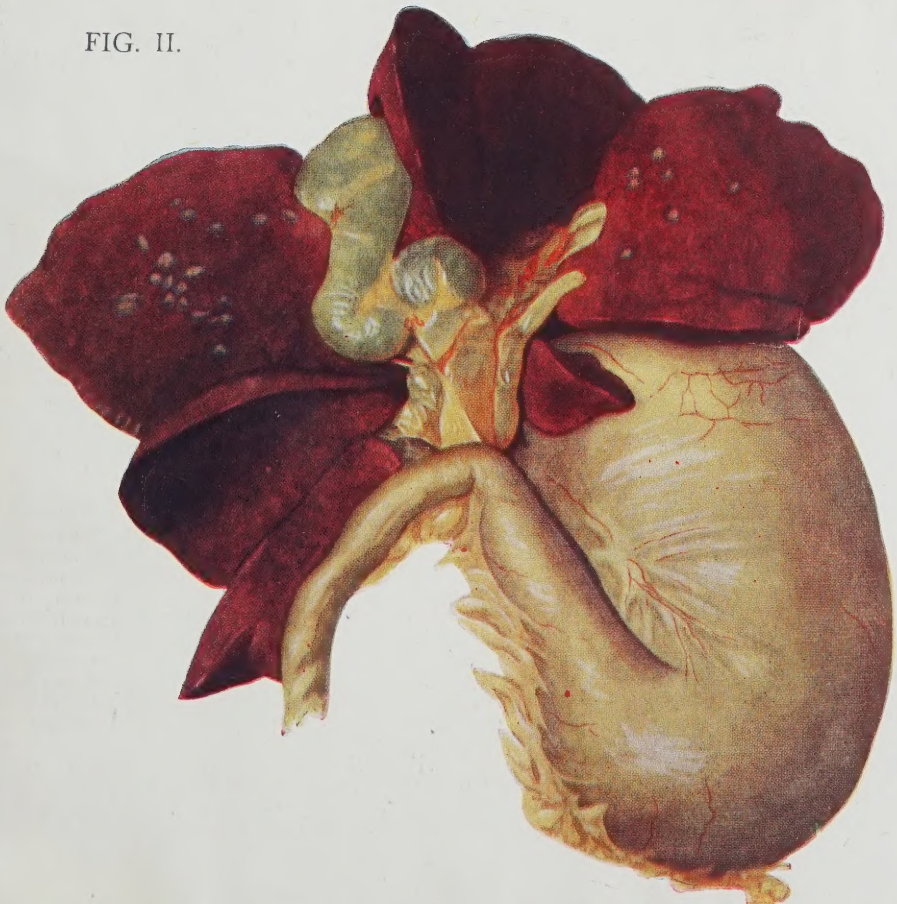

FIG. II.—Biliary passages, including gall-bladder, distended with "white bile" 15 days after ligature of common bile-duct.

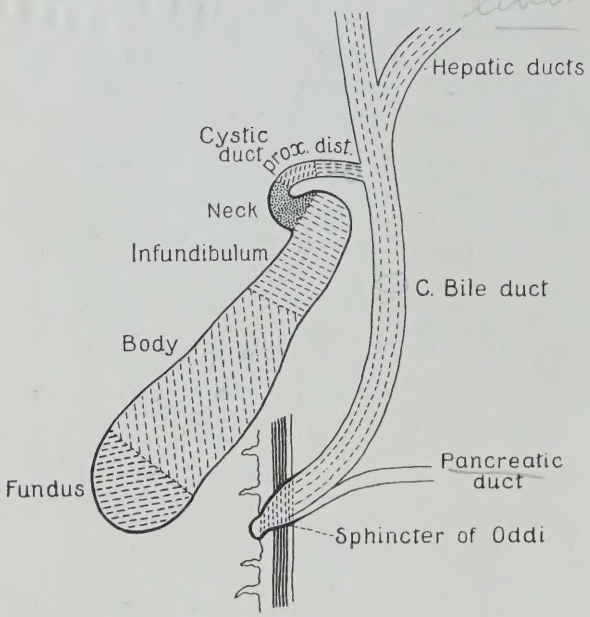
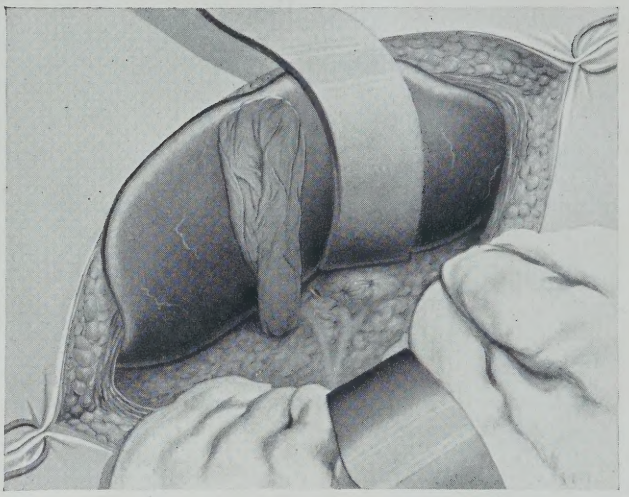
FIG. III.



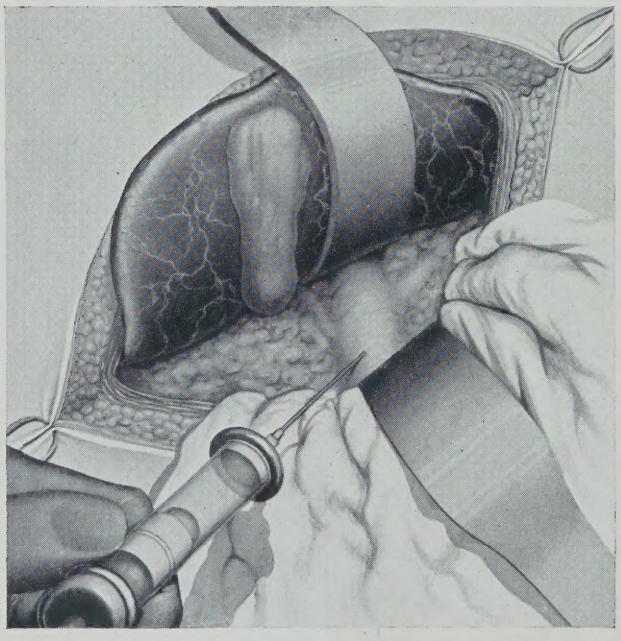
Anatomical divisions of gall-bladder and ducts. The thickness of the outline indicates the relative amount of muscle in the wall.

FIG. IV.



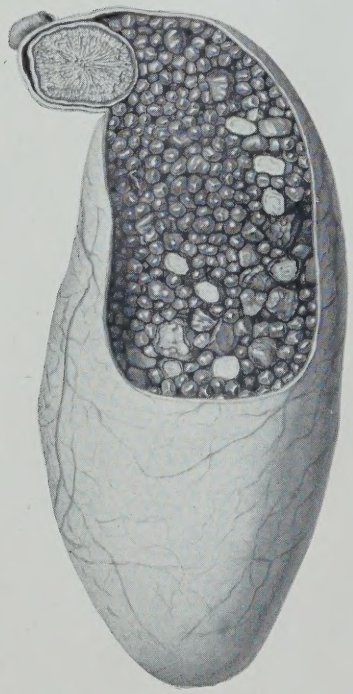
The empty gall-bladder. Tumour involving both hepatic ducts. The patient was intensely jaundiced.

FIG. V.



Aspiration of "white bile" from the common bile-duct. A calculus completely blocked the lower end of the common bile-duct and another the neck of the gall-bladder. Distended bile radicles are visible on the liver surface.

FIG. VI.



Gall-bladder with "combination stone" (cut across to show structure) in the neck and numerous facetted secondary septic stones.

proportions in which the latter are present. Any disturbance of metabolism or of the excretory power of the liver which leads to an increase in the cholesterin content of the bile or to a diminution in amount, or altered proportion of the various bile acids, might lead to a precipitation of cholesterin in the gall-bladder. This would be the more likely if, in addition, any factor leading to exaggerated stasis and resorption in the gall-bladder were also present. Increase of the cholesterin of the blood, cholesterinæmia, has been demonstrated in the human subject during pregnancy, in starvation and other conditions associated with a rapid loss of fat, and in arterio-sclerosis. Whilst an increase in the bile cholesterin cannot always be demonstrated in these conditions, the close relation between the cholesterin content of the bile and that of the blood was shown by Bacmeister and Havers in the case of bitches which had recently borne young but were prevented from suckling. Whilst Naunyn believes that the gall-bladder may excrete cholesterin even in the absence of any demonstrable inflammatory change in its wall, and Rovsing maintains that minute bile cylinders of pigment calcium, shed off from the intra-hepatic bile capillaries, form the nuclei of all gall-stones, the evidence in favour of Aschoff's metabolic theory of origin of the single cholesterin stone is convincing and accords with surgical experience. The unique character of this single stone, its "silent" and afebrile residence within the gall-bladder, distinguish it from other types of which the inflammatory origin is beyond dispute.

There is a second type of stone which would appear to arise as the result of metabolic disturbance—namely, the pure pigment stone, always multiple, of mulberry shape, hard, and brittle with metallic sheen and often brightly coloured, without a distinguishable nucleus and with no trace of lamellation; this type of stone is composed of pure bilirubin calcium. It is found in gall-bladders showing no trace of present or past infective mischief and in many cases of hæmolytic jaundice.

Septic Gall-stones.

The single cholesterin stone or the pigment stones described above may remain innocent and "silent" for years. Not infrequently, however, and especially in the case of the cholesterin solitaire, the stone becomes impacted in the neck of the gall-bladder and obstructs it completely, causing an afebrile attack of colic. Coincident with and dependent on this there is a spasm of the sphincter of Oddi so that bile stasis results in both bladder and ducts. Under such circumstances infection is very liable to be superimposed. The route taken by the infection is difficult to determine; in many cases, however, it would appear to be by the blood stream. The gall-bladder is now the seat of an acute obstructive cholecystitis and muco-pus gradually replaces the bile and distends the gall-bladder.

If the stone remains impacted and the infection subsides a mucocele of the gall-bladder results. More frequently, however, as the infection dies down the resorptive function of the bladder comes into play, tension decreases, the single stone disimpacts and falls back, and bile enters anew. Now is the time for the genesis of multiple stone formation. The bile entering the gall-bladder, the motility of which is crippled and impaired by recent inflammatory changes, mixes with the muco-purulent content. The latter, with its precipitated proteins, leucocytes, desquamated epithelium and micro-organisms, furnishes just the medium for a precipitation of cholesterin-bilirubin-calcium in multiple, granular, semi-crystalline masses. Many of these crystallise out on the surface of the cholesterin stone on which a new cortex is deposited, thus forming what is termed the "combination stone." Many of the little masses of cholesterin-pigment-calcium, however, act as the nuclei for new stones, later seen as the typical facetted stones of lamellated structure.

We thus see how the primary single cholesterin stone may lead to obstruction, inflammation, and secondary septic stone formation, and may itself become enclosed in a shell of the mixed material of which the large family of infective stones is composed. Later obstructive attacks may be followed by further broods of stones, more often, however, by accretion to those already formed. So constant is this sequence that at operations for acute obstructive cholecystitis the surgeon is not satisfied, after opening the gall-bladder, evacuating the pus and, it may be, a hundred faceted stones, until he delivers the ovoid combination stone, usually the largest, from the neck of the gall-bladder or the cystic duct (Fig. 6).

Primary Septic Stones.

Cholecystitis occurs frequently without any obstructing stone being present. From the walls of the inflamed gall-bladder there is poured out an exudate rich in calcium and protein. This mixes with and partly replaces the bile. During the acute stage of the inflammatory process little or no bile can enter the gall-bladder, but as the inflammation subsides and the inflammatory exudate becomes in part absorbed, bile again mixes with the now inspissated exudate which furnishes numerous centres of crystallisation. Rosettes of cholesterin-pigment-calcium form and, later, agglutinate into masses rich in protein. As fresh bile now arrives a slower process of crystallisation occurs, and on the soft, radiate, central nucleus a laminated, more compact, and harder shell is deposited. This shell contains more cholesterin and less calcium than the softer centre. Where the calculi can move about within the gall-bladder they have the typical faceted shape due to accretion at the exposed angles: where, as in small and thick-walled gall-bladders, movement is less easy, they assume a barrel shape with facets at either end where in contact with each other.

BILIARY STASIS.

All writers on biliary diseases are agreed on the importance of stasis in the biliary passages as a factor in the ætiology of both infection and calculus formation. The relative frequency of gall-stones and of cholecystitis in the female sex, especially in multiparous women, suggested the upward pressure of the pregnant uterus and the wearing of corsets as causes of biliary stasis. The not infrequent occurrence of gall-stones in males, in nulliparous females, and the present-day prevalence of this malady, when corsets are no more, indicate that other factors than pressure from without may produce stasis. Of late years much attention has been directed to local factors within the biliary passages themselves which tend towards stasis.

The Stasis Gall-bladder.

Aschoff was the first to describe, under the term "Stauungs Gallenblase," a condition of chronic stasis in the gall-bladder associated with well-defined microscopic changes in its wall occurring independently of stone formation or infection, although liable to be complicated by one or both of these conditions. Berg, in a series of very thorough investigations, differentiated two main types of stasis gall-bladder. In the first the main feature is the increased secretion of mucus by a gall-bladder with well-developed muscular wall and, in this, there develop secondary obstructive phenomena from kinking at the neck. Such a gall-bladder has always a pale mucoid content and is liable to be the seat of cholesterin stone formation. Berg terms this "muco-stasis." The second type, that of "cholestasis," is met with in biliary passages of lower muscular tone with a weaker sphincter. The gall-bladder is dilated, has unimpaired resorptive capacity, and contains dark concentrated bile. In it pigment calcium stones are liable to form.

Schmieden and Rohde have recorded a series of cases, presenting symptoms resembling biliary colic, in which at operation no calculi and no evidence of infection were apparent, but in which obstruction to the outflow was present from kinking at the neck of the gall-bladder, due, in their opinion, to congenital malformation. In all these cases removal of the

gall-bladder gave complete relief from pain. Schmieden recognises three pathological stages in the stasis gall-bladder. In Stage I. the wall shows venous congestion, lymphoid hyperplasia, and slight muscular hypertrophy; in Stage II. the muscular hypertrophy is more pronounced and connective tissue increase is found; in Stage III. atrophic changes with fibrous tissue replacement of the muscle predominate. All observers agree that in many of these cases there is a coincident enlargement and distension of the common bile-duct.

Hypertonic Type of Stasis Gall-Bladder.

Without controverting the views of Berg and Schmieden on the ætiology of the stasis gall-bladder, there is much to be said in favour of the view of Westphal that in these cases the primary and dominant factor is a spasm of the sphincter of Oddi and of the ring of musculature at the junction of neck and cystic duct, leading to secondary dilatation and hypertrophy of the gall-bladder wall—i.e., hypervagotonus determines the condition. We have here a very interesting light thrown on the stasis factor in the biliary tract so universally recognised to be the basal element for biliary lithiasis and infection.

The fact that, in a proportion of the cases in which a "stasis gall-bladder" was found at operation, a single cholesterin stone was present, whilst in others it was not, is a valid argument in favour of the obstructive element, be it kinking or spasm, being the primary factor, and stone formation the secondary result. Not only may stone result from this form of stasis, infection is liable to follow and may occur prior to or independent of any stone formation. The incidence of infection in the stasis gall-bladder will tend to increase the spastic symptoms just as dysentery may cause spastic and painful contractions of the colon. The vicious circle of spasm and infection explains many pathological findings in the gall-bladder as it does many a clinical history.

Biliary Trouble in Pregnancy.

The onset of biliary trouble in relation to pregnancy is proverbial, the association of biliary attacks with menstrual periods less well known but still undoubted. Increase of the blood cholesterin in pregnancy is an oft-repeated observation and now an accepted fact. A corresponding increase in the bile cholesterin is not regularly present during pregnancy. Hypercholesterinæmia and bile stasis from the gross mechanical pressure of the rising uterus together with a tendency to *B. coli* infection traceable to constipation are recognised reasons for the origin of biliary trouble in the later months of pregnancy. Westphal has shown, however, that in pregnant women, after injection of pilocarpine, duodenal intubation proves that there is that initial spasm of the sphincter of Oddi indicative of a hypervagotonus. To this latter condition may be attributed the biliary stasis as also the morning sickness and salivation so frequently seen during the early months of pregnancy. In 9 out of 11 pregnant women Westphal found a hypersensitiveness of the sphincter of Oddi with consequent biliary stasis during the early months of pregnancy when the upward pressure of the uterus could not be considered as an active factor.

The experiments of Storm van Leeuwen and Van der Broeke on the cat's intestine showed that the addition of cholesterin increased the action of pilocarpine, and in the human subject Kaufman and Billigheimer found that in cases of arterio-sclerosis, where increase of cholesterin in the blood was determined, there was an extreme hypersensitiveness to pilocarpine. The cholesterinæmia of pregnancy, therefore, may be potent for gall-stone formation, more from its effect in producing vagotonia and bile stasis than from its supposed influence on the cholesterin content of the bile. Recognising, as we now do, the existence of pathological conditions and clinical entities in the heart, œsophagus, stomach, and intestine, due to dysfunction of the nerve-controlling mechanism, it would be strange did some such disorders not occur in the highly specialised biliary apparatus. We have now sufficient proof to warrant us in believing that hyperkinetic neurosis of the bile passages may cause functional disorders leading not only to pain from muscular spasm, but later to definite biliary stasis with stone formation and inflammatory disease. Achalasia of the bile passages has not, so far as I know, been described. That it does occur seems more than likely, and incoördinate action, with a failure of the sphincter to relax, may account for the rare condition of cystic dilatation of the common bile-duct and bring this striking anomaly into line with such conditions as Hirchsprung's disease of the colon, cardiaspasm, congenital pyloric stenosis, and some forms of hydronephrosis.

Hypotonic Type of Stasis Gall-bladder.

It is in keeping with our knowledge of other hollow viscera that we should find that a *hypotonic* condition of the bile passages may bring about a condition of bile stasis which may lead to infection and stone formation. Berg has described two types of gall-bladder (his Types II. and III.), in which the striking features are thin lax walls, funnel-shaped cystic duct, with, later on, some degree of kinking over the cystic artery. Such gall-bladders resemble closely those seen in animals after paralysis of the vagus by atropine or stimulation of the sympathetic. Such a hypotonic condition of the biliary passages tends to stagnation in the gall-bladder, to increased resorption of water, and thus to aseptic or infective stone formation. This type is met with in asthenic ptosis and represents but a part of a general weakness and lack of tone. In these cases this stasis may be aggravated by anatomical causes tending to bile stasis. In the acquired ptosis of old age, in flabby stout people, and in the subjects of arterio-sclerosis, there is the additional element of increased cholesterin content in the blood which has been demonstrated in such subjects.

All surgeons are familiar with the type of case in which the history and symptomatology are strongly suggestive of gall-bladder trouble where operation reveals a large, flabby, dilated gall-bladder with marked pouching of the infundibulum, but with no calculi and little or no evidence of past or present inflammatory change. In such cases the surgeon usually confesses that the diagnosis has been wrong and contents himself with removing a more or less innocent-looking appendix. The symptoms, however, persist after operation. I have met with cases where two or more such negative abdominal explorations for biliary symptoms have been carried out, in which the patient has been finally relieved by the removal of the gall-bladder. We meet with so many instances of gross lesions, such as stones and frank inflammatory thickening of the gall-bladder wall, that when these are lacking we tend to overlook the subtler changes which may have an equal significance in producing pain and disability for the patient.

The Relation of Biliary Affections to Pancreatic Disease.

The frequent association of a certain degree of pancreatitis with gall-bladder disease is proverbial. As a rule, it is of the nature of a localised sclerosis in the head of the pancreas, sometimes, however, a more widespread change in the pancreas is found. In cases of acute and subacute pancreatitis evidence of disease, usually in the form of gall-stones, in the biliary passages is found. It is customary to attribute the pancreatitis to infection spreading from the gall-bladder or common duct, either by way of the latter or by a retrograde lymphangitis. Archibald suggested that infection was of secondary importance and that regurgitation of bile into the pancreatic duct due to spasm of the sphincter of Oddi was of primary importance. Several facts support the validity of his views. Firstly, in cases of florid acute cholecystitis it is rare to find an acute pancreatitis. Secondly, my experience has been that in fulminating cases of acute pancreatitis, although the gall-bladder is often dilated

and contains stones, it shows no evidence of recent inflammation and the bile within it may be sterile on culture. Thirdly, a bile-stained peritoneal exudate is frequently found in these acute cases.

It seems possible that in this condition a spasm of the distal papillary part of the sphincter of Oddi with relaxation of the portio duodenalis permits, on the one hand, of bile entering the pancreatic duct and so causing the primary pancreatic necrosis; and, on the other hand, of pancreatic secretion entering the common bile-duct and thus allowing bile-pigment to diffuse through the wall of the duct, a consequence which experiment has proved to be possible. Mann and Giordano have demonstrated the presence of sphincteric fibres round the terminal portion of the common duct, the contraction of which might throw the biliary and pancreatic channels into one. It is thus that we find acute pancreatitis supervening in elderly flabby subjects with hypotonic biliary passages, often with gall-stones, but very rarely with active inflammation in the biliary tract.

OBSERVATIONS ON TRYPARSAMIDE THERAPY IN NEURO-SYPHILIS.

(Preliminary Report to the Medical Research Council.)

BY J. D. SILVERSTON, M.B., B.S. DURH.,

SENIOR ASSISTANT MEDICAL OFFICER, COUNTY MENTAL HOSPITAL, WHITTINGHAM, PRESTON.

IN January, 1924, through the courtesy and generosity of the Medical Research Council, a preliminary study was undertaken to determine the value of tryparsamide in the treatment of neuro-syphilis as well as its toxicity and untoward reactions, if any.

The material on which this study is based consists of 18 cases of neuro-syphilis, one case of encephalitic psychosis, and a case of Huntington's chorea. At the outset ten cases only were available for treatment, all of whom were general paralytics, but additions to the series have been gradually made with the result that a total of 15 cases of paresis (including one case of juvenile general paralysis), three of meningo-vascular neuro-syphilis, and two non-syphilitic cases, have been under treatment and observation during the past 12 months. The amount of tryparsamide administered to each patient has varied with the time of onset of treatment, the attitude of the patient during the course, and the development of untoward symptoms. I particularly stress the second factor, as my lot has been to contend with great opposition in the treatment of most of my late cases of paresis, so that a fair trial of the drug in that class of patient could not be given.

Valuable experience has been gained in this hospital during the past two and a half years in the malarial treatment of general paralysis, but although we have met with very encouraging clinical results in a good number of cases, the serological results have been less pronounced. It was therefore decided to try the effect of tryparsamide in a series of seven general paralytics who had already received a course of malarial treatment, and to observe whether the addition of the drug brought about a more rapid cure clinically and at the same time serologically.

The cases studied may be classified in four main groups:—

CLASS A.—Tryparsamide only. Eight cases of general paralysis who had received no previous treatment: early cases, 2; late cases, 5; juvenile case, 1.

CLASS B.—Malaria and tryparsamide. Seven cases of general paralysis who had received one course of malaria treatment: early cases, 2; late cases, 5.

CLASS C.—Tryparsamide only. Three cases of meningo-vascular neuro-syphilis: early cases, 1; late cases, 2.

CLASS D.—Tryparsamide only. Two miscellaneous cases: post-encephalitic psychosis, 1 case; Huntington's chorea, 1 case.

In Classes A, B, and C mercury in the form of mercury salicylate has been also employed, and 17 cases of neuro-syphilis received this combined form of drug therapy.

Types of Cases.

The term "early case" has been applied in this series to those general paralytics with a history of not more than six months' mental disturbance prior to admission. "Late" has been reserved for more advanced cases and includes the "fat, fitty" variety as well as the infirm and bedridden. As a pronounced clinical improvement was not anticipated in the latter group the serological results became of prime importance, and formed a criterion of the therapeutic value of the drugs employed.

Technique of Treatment.

Tryparsamide, wherever possible, was administered intravenously in weekly doses of 3 g., over a period of eight or ten weeks. The drug was given in a 30 per cent. solution, obtained by dissolving 3 g. of the salt in 10 c.cm. sterile freshly-distilled water. The subcutaneous route was used in three patients (Cases 5, 6, and 7) because in them any attempt at intravenous medication was likely to be fraught with considerable danger.

Mercury in the form of mercury salicylate was administered intramuscularly into the buttock in 1 gr. doses. The mercury was given at the same time as the tryparsamide, and a total of eight or ten injections of tryparsamide and mercury comprised a single course. It was then the practice to institute a rest interval or drug-free period of six to ten weeks, after which a second similar course was repeated. A further period of rest was again ordered, and a third course, if necessary, given.

The grand total of injections, including those introduced by the subcutaneous method, numbered 242 of tryparsamide and 199 of mercuric salicylate. During the period at my disposal two cases only received three full courses (25 to 28 injections) of treatment; three patients have received two courses (18 to 20 injections); six cases one course (8 to 12 injections), and four an incomplete course of five to seven doses. In the meningo-vascular group one patient received two courses of treatment, and two patients one complete course of combined therapy.

Examination of Patient.

Besides the usual clinical, mental, and neurological examinations a full investigation of the chemistry and serology of the blood and cerebro-spinal fluid was made in each patient. Specimens were taken where possible before, during, and following the courses of treatment in order to find out whether serological improvement was taking place and if parallel improvement in the clinical and laboratory findings could be recorded.

The cerebro-spinal fluid examinations comprised the following: colloidal gold reaction of Lange; colloidal gamboge test of Riddel and Stewart; estimation of globulin content by the tests of Ross-Jones and Pandy; estimation of the cell content (Fuchs-Rosenthal); sugar concentration; and Wassermann reaction (W.R.).

The blood examinations performed were the estimation of the sugar content and the Wassermann reaction.

The estimations of the sugar content of the blood and cerebro-spinal fluid were carried out according to the method of Folin and Wu. Slight modifications of the technique were followed in the spinal fluid estimations.

The Van den Bergh, Fouchet, and Lowenhart lipase tests of the blood serum were performed where impaired function of the liver was suspected as a result of treatment with tryparsamide. The Fouchet test was carried out in the bloods of all the cases on completion of the course of

treatment, in order to detect where present the condition known as hyperbilirubinæmia or latent jaundice.

Weight charts were kept of each patient throughout the periods of treatment and observation.

Clinical Findings.

The clinical results based on observations made on the whole series of cases treated during the past year have been satisfactory, and to facilitate their readings summaries have been given in tabular form and according to their classification.

CLASS A.—*Cases of Paresis treated by Tryparsamide only.*

Classification.	Recovered.	Improved.	Unchanged.	Died.
Paresis { early (2 cases) .	2	—	—	—
Paresis { late (5 ,,) .	—	—	4	1
Paresis { juvenile (1 case) . .	—	1	—	—
Total . . . . 8 cases	2	1	4	1

The term "recovery" is used exclusively to denote cases that have reached a state of complete remission; where the patient has regained his full working power and shown complete freedom from demonstrable psychical defects; "improvement" is used where the progress of the disease has become stationary, or where the patient has developed a partial remission with a residual psychical defect. The early cases began to show signs of recovery a few weeks following the completion of the first course of treatment. Excellent progress was maintained in both cases during the second course, and in the interval that followed the patients were discharged recovered in a state of complete remission.

CASE 1.—H. F., male, aged 44; admitted Jan. 19th, 1924, discharged August 30th, 1924.

History.—In the early part of December, 1923, he developed numerous grandiose ideas, habits of extravagance, euphoria, paramnesia, and impairment of reasoning and judgment.

Central Nervous System.—The pupils were regular but unequal, and the reactions were all sluggish; pupillary oscillations were absent, and the oculo-spinal sympathetic reflexes were sluggish. Speech was rapid, but slightly though definitely impaired by tremors and hesitancy over certain test words. The tongue showed no tremor; expression of the face was relaxed and the muscles atonic. There was a general increase in the deep reflexes of all the limbs; the superficial reflexes were brisk and equal. Handwriting showed well-marked tremors and elision of syllables in the spelling of simple words.

Physical Examination.—Physique fair, the heart, lungs, and abdominal viscera apparently normal. Weight 8 st. 8 lb.

Serology.—C.S.F.: colloidal gold 5555321000; colloidal gamboge 222210; globulin one plus; cells 53·3 per c.mm.; sugar content 0·118 per cent.; W.R. positive.

Blood: W.R. positive in 1 in 15 dilution; sugar content 0·12 per cent.

Treatment with tryparsamide and mercury was commenced on Jan. 22nd, 1924, and eight weekly injections were administered to March 11th, 1924, when a rest interval was ordered. His mental state did not show the slightest improvement. Following the sixth injection the blood and spinal fluid were as follows:—C.S.F.: colloidal gold 5542100000; colloidal gamboge 221000; globulin one plus; cells 7 per c.mm.; W.R. negative. Blood: W.R. doubtful in 1 in 2 dilution. His body-weight began to improve, and with the last dose there was a gain of 5 lb. A rest interval of eight weeks was given and towards the end of that period his mental state began to show improvement. He talked less, ridiculed his former statements as delusions, and made sensible inquiries concerning his wife and family, his illness, and prospects of recovery. He had gained 12 lb. in weight at the end of the drug-free interval, and the serological readings were:—C.S.F.: colloidal gold $\frac{55}{5444321000}$; colloidal gamboge 221000; globulin one plus; cells 11·6 per c.mm.; sugar 0·08 per cent.; W.R. negative. Blood: W.R. weakly positive 1 in 4; sugar 0·08 per cent.

A second course of ten weekly injections of tryparsamide and mercury was instituted on May 13th, 1924, and during this period the improvement continued and he became a useful member of the community. He enjoyed the full privileges of parole within the grounds, and often expressed his appreciation for the keen interest that was taken in his case. After the last dose of his second course four weeks were allowed to elapse before another serological examination was made. C.S.F.: colloidal gold 0011210000; colloidal gamboge 100000; globulin faint trace; cells 3·6 per c.mm.; sugar 0·059 per cent.; W.R. negative. Blood: W.R. negative; sugar 0·12 per cent.

No further treatment was given, and patient was discharged recovered at the end of August, 1924. He has since returned to his former employment, and a letter from him, dated May, 1925, stated that he was well.

This case is of particular interest in that the clinical and serological findings ran in parallel paths towards complete recovery. The cerebro-spinal fluid readings, apart from the "sub-luetic" curve in the gold-sol, are normal. The physical signs showed no improvement except that his handwriting, speech, and muscular coördination had returned to normal. The weight at the end of treatment showed an increase of 15 lb.

The second case of early paresis recovered with the same amount of treatment. The serological recovery, however, was less pronounced.

CASE 2.—J. D., male, aged 33; admitted Dec. 31st, 1923, discharged August 30th, 1924.

History.—The patient was described by his wife as having been strange in his habits for four months and as having occasionally suffered from "twitchings" of the limbs.

On admission he seemed unaffected by his transfer to hospital, and was found to be disorientated for time and place. He was paramnesic and would steal other people's belongings and hoard them for no apparent reason.

Central Nervous System.—The pupils were unequal and irregular, the reactions to light sluggish; to accommodation and convergence sluggish, but with fair excursion; pupillary oscillations and oculo-spinal reflexes were sluggish. His articulation was drawling, tremulous, and hesitating, particularly over certain test words. There was a general increase in the tendon reflexes of the limbs, and the superficial responses were brisk and equal. Coarse tremors were manifested in the outstretched hands, and handwriting was shaky and "heavy."

Physical Examination.—Physique good, heart and lungs apparently normal.

Serology.—C.S.F.: colloidal gold 5555321000; colloidal gamboge 222220; globulin 2 plus; cells 89·3 per c.mm.; sugar 0·08 per cent.; W.R. positive. Blood: W.R. strongly positive in 1 in 45; sugar 0·086 per cent.

Treatment with tryparsamide and mercury was commenced on Jan. 22nd, 1924, and a single course of eight weekly doses was given. His habits did not improve during treatment. Following the sixth inoculation his serological readings were:—C.S.F.: colloidal gold 5554321000; colloidal gamboge 222100; globulin one plus; cells 8 per c.mm.; W.R. positive. Blood: W.R. positive in 1 in 15 dilution.

A rest interval of eight weeks was given, during which he showed gradual improvement except for two serious lapses of conduct. Prior to his second course his mental state and conduct were sufficiently improved to be regarded as normal, and a further examination of his blood and spinal fluid was made:—C.S.F.: colloidal gold 5554321000; colloidal gamboge 222100; globulin one plus; cells 4·3 per c.mm.; sugar 0·083 per cent.; W.R. positive. Blood: W.R. positive 1 in 5; sugar 0·11 per cent.

The weight during the first course increased by 13½ b., but dropped by 4½ lb. in the succeeding rest interval.

A second course of ten injections was given and concluded by July 15th, 1924, when he lost a further 5 lb. No further treatment was given as patient had made a complete mental recovery. His mind was clear, his memory and orientation good, and his insight extraordinarily good. Speech and writing defects had disappeared, but the other physical signs were unaffected. The serology at this stage read:—C.S.F.: colloidal gold $\frac{555}{4444321000}$; colloidal gamboge 221000; globulin one plus; cells 3·6 per c.mm.; sugar 0·069 per cent.; W.R. positive. Blood: W.R. weakly positive 1 in 8; sugar 0·10 per cent.

Patient was discharged recovered on August 30th, 1924, and returned to his former employment. A letter later received stated that he was quite well and working regularly.

The treatment of the late cases of general paralysis has been unsatisfactory and disappointing. In one patient only (Case 3) was it possible to administer three full courses of treatment, as in the remainder the resistance of the patient prevented a fair trial of the drug. Consequently the clinical and serological results of this group of cases are of little interest.

CASE 5.—W. A., male, aged 35. Was admitted to hospital in January, 1923, in a state of acute mental confusion. The

physical signs were typical of general paralysis. and the serological findings were :—C.S.F. : colloidal gold 5555421000 ; colloidal gamboge 122210 ; globulin one plus ; cells 160·3 per c.mm. W.R. positive. The blood W.R. was positive in 1 in 15 dilution. Treatment was instituted in January, 1924, and 21 g. of tryparsamide and 3 gr. of mercury salicylate were given over seven sittings. Further treatment has been impossible owing to the maniacal behaviour of the patient, but an examination of his serology indicates considerable improvement. The W.R. of the blood and spinal fluid were negative. the colloidal gold and other reactions read : colloidal gold 1122110000 ; colloidal gamboge 221000 ; globulin, trace ; and cells 16 per c.mm.

A case of juvenile general paralysis (Case 4) appears in the list of patients subjected to tryparsamide and mercury treatment, but owing to the patient's aggressive attitude only a single course has been permitted.

CASE 4.—J. F. M., male, aged 17 ; admitted June 26th, 1924.

History.—Patient was found wandering about a seaport city and could give no information regarding himself or his parents, and inquiries have proved fruitless.

On admission patient was mentally unstable, laughing and crying without reason. He suffered from aphasia, and his replies to simple questions consisted of a repetition of such words as " Joe," " Yes," or " No." When given a banana he did not know what to do with it, but lit and smoked a cigarette. His responses to simple commands, such as " Shake hands " or " Put out your tongue," were delayed and imperfect. He probably suffered from agraphia, as he was unable to write a name to dictation.

Physical Condition. — Patient's appearance and stature suggest a much younger boy. Stigmata of congenital syphilis were found.

Central Nervous System.—The pupils were unequal and dilated ; the left was irregular ; reactions to light were sluggish, but those to convergence and accommodation were impossible to ascertain ; oscillations of the pupil and the sympathetic reflexes were absent. There was a well-marked fibrillary tremor of the labial muscles whenever the patient attempted to speak. Gesticulations were frequent. Knee and tendo-Achilles jerks were absent on both sides. The plantar responses were flexor. There was no impairment of sphincteric control. Sensation was apparently normal ; Abadie's test for deep sensibility negative. Gait was steady, although there appeared to be at times a slight hesitation in the movement of the right lower limb.

Serology.—C.S.F. : colloidal gold 5555543210 ; colloidal gamboge 122220 ; globulin one plus ; cells 45 per c.mm. ; sugar 0·045 per cent. ; W.R. positive. Blood : W.R. strongly positive 1 in 45 ; sugar 0·088 per cent.

Treatment with tryparsamide and mercury was commenced on July 1st, 1924. The usual dosage was altered in this youthful case and the first injections consisted of 2·5 g. of tryparsamide and 1 gr. of mercuric salicylate. The remaining inoculations varied from 2·1 to 2·5 g. of tryparsamide and 0·5 to 1·0 gr. of mercury with two 14-day intervals between the second and third, and the fourth and fifth injections respectively. The total amount administered during the course of eight injections consisted of 19·2 g. tryparsamide and 5·5 gr. of mercuric salicylate. Apart from slight attacks of vomiting after the early injections, the course was well tolerated. No further treatment as yet has been possible, although many attempts have been made to overcome his resistance.

During the period of treatment his physical state improved, and there was a gain in weight of 6 lb. His mental state, however, remained unchanged. He remained unduly irritable, and when dissatisfied smashed windows or plates.

Ten to 12 weeks after the last injection an improvement in his mental state was noted ; he became better behaved and more amenable to reason, while outbursts of passion and turbulence disappeared. His habits improved. Serious setbacks in the nature of epileptiform seizures occurred during the evenings of Oct. 29th and Dec. 23rd, 1924, but recovery from both was prompt and rapid. His body-weight now registers 8 st. 10 lb. or a total gain of 35 lb. C.S.F. : colloidal gold 1122110000 ; colloidal gamboge 100000 ; globulin trace ; cells 8 per c mm. ; sugar 0·062 per cent. : W.R. positive. Blood : W.R. strongly positive 1 in 45 ; sugar 0·08 per cent.

The clinical results obtained in the combined fever and drug treatment of cases grouped in Class B showed no marked superiority over those already discussed, and a reference to the summary given below will illustrate that practically the same number of early and late cases have been utilised for comparison.

Seven patients suffering from general paralysis were subjected to a course of treatment with malarial fever. The benign tertian strain was exclusively used and a number of rigors, varying from six to ten, was induced in each case and arrested by quinine. A period of rest of five to ten days was allowed to elapse before treatment with tryparsamide and mercury was commenced.

CLASS B.—*Cases of Paresis Treated by Malaria and Tryparsamide.*

Classification.	Recovered.	Improved.	Unchanged.	Died.
Paresis { early (2 cases) ..	2	—	—	—
Paresis { late (5 „) ..	—	1	3	1
Total .. 7 „ ..	2	1	3	1

These arsenical and mercurial preparations did not materially influence the course, clinical or serological, of the cases treated by malaria inoculation. In our experience with this form of fever treatment a fairly accurate prognosis can frequently be offered soon after the cessation of treatment. In Cases 10, 12, and 14, all of whom have been discharged to their homes, a hopeful prognosis was anticipated before treatment with tryparsamide was commenced. It cannot be said at this stage that their rates of recovery were accelerated, or that the clinical results have been rendered more stable, as complete clinical recoveries have been obtained with malaria treatment only, and patients have remained at home, and at work, for periods varying from three to 18 months. Again, a comparison between the post-malarial serology of Case 9 and the laboratory findings at the completion of the malarial and drug treatment of Case 10 will confirm the opinion already expressed above that the addition of tryparsamide to the malarial treatment of general paralysis has not been attended by any better or worse results than those obtained with the malarial treatment alone.

One death took place in a patient treated by this method, not as a result of malaria or tryparsamide, but indicating the inability of the fever or drug to arrest the progress of the disease.

CASE 11.—F. M., male, aged 47, was admitted in November, 1923, with late general paralysis. There was extreme dementia with mental confusion and characteristic neurological and speech anomalies. The spinal fluid was quite typical. He received a course of malarial treatment (ten rigors) which ended on Dec. 16th, 1923, but as no improvement resulted further treatment by tryparsamide and mercury was started. He received six injections of both drugs, but deteriorated rapidly, became feeble and bedridden, developed amblyopia and conjunctivitis, and died a typical general paralytic death.

Treatment has been discontinued in one case owing to the development of seizures half way through the course.

CASE 15.—C. D., male, aged 47, was admitted in March, 1924, because of gradual failure of memory and inability to carry on his business as a master tailor for the previous two years. On admission he was euphoric and grandiose. The neurological picture was typical of general paralysis with well-marked speech defects. Laboratory findings were :—C.S.F. : gold-sol 5554432100 ; colloidal gamboge 222210 ; globulin one plus ; cells 13 per c.mm. ; sugar 0·07 per cent. ; W.R. positive. Blood : W.R. positive 1 in 10 ; sugar 0·09 per cent. An inoculation with malarial blood was performed in April, 1924. At the end of the third rigor patient became very anæmic and exhausted, and albumin in large quantities appeared in the urine. Treatment was immediately cut short with quinine, and an interval of rest ordered. A month later patient had sufficiently improved physically to undergo a further fever course, and a second inoculation was administered, which was again successful, and at the end of the ninth rigor treatment was again arrested by the oral exhibition of quinine. A lumbar puncture performed a few days after the finish of the fever course gave the following results :—C.S.F. : gold-sol 5555432100 ; colloidal gamboge 22210 ; globulin one plus ; cells 10 per c.mm. ; sugar 0·077 per cent. ; W.R. doubtful. Blood : W.R. weakly positive 1 in 8 ; sugar 0·118 per cent. Tryparsamide and mercury treatment was commenced on July 8th, 1924, and repeated at weekly intervals without apparent ill-effects until five days following the fifth injection, when patient had fever and signs of meningeal

irritation. A status epilepticus of 77 seizures supervened, and his life was despaired of. (For further notes on this case vide the section on "Reactions following the use of Tryparsamide.") No further treatment was given and patient gradually improved, but an attack of mild arsenical jaundice four weeks later again embarrassed him. At the time of writing, however, he has sufficiently improved to be allowed up all day and to enjoy the privileges given to well-behaved patients. His mental state, however, shows no improvement; he is euphoric and deluded.

Clinical and serological improvements do not necessarily run parallel with each other, as two patients (Cases 9 and 13) with general paralysis, in whom the spinal fluid and blood readings became completely negative after treatment, exhibited no mental change.

A summary of the combined results obtained in the treatment of cases of Classes A and B reads:

CLASSES A AND B.

Classification.	Recovered.	Improved.	Unchanged.	Died.
Paresis { early (4 cases).	4	—	—	—
Paresis { late (10 ,,).	—	1	7	2
Paresis { juvenile (1 case).	—	1	—	—
Total .. .. 15 cases	4	2	7	2

Of a total of 15 cases of general paralysis treated during the past year by tryparsamide, and malaria and tryparsamide respectively, five, or 33·3 per cent., have recovered, and have been discharged from the institution. All four early cases have made a complete clinical recovery, while one patient with late paresis has returned home to his former employment with a slight residual memory defect. It will be seen that the late cases of the group have done badly, as two died and seven were unimproved.

Meningo-vascular Neuro-syphilis.

The results obtained in the treatment of this variety of brain syphilis are limited to the observations made on three cases over a period varying from three to eight months.

Improvement has occurred in two patients, one an early case in which treatment is being continued, and one a late case with chronic hemiplegia. In the latter, treatment was stopped at the ninth injection as symptoms suggesting the development of amblyopia occurred. In the third case, after a preliminary and apparently brilliant recovery, treatment had to be stopped, as patient became much worse and gradually deteriorated.

CASE 16.—A. C., male, aged 36, labourer; admitted March 22nd, 1923.

History.—Patient contracted syphilis in 1907 and received a course of mercury inunctions and oral potassium iodide over a period of 12 months. In 1912 he contracted malaria. He served during the war in France till the end of 1917. He was rendered unconscious by a shell explosion in August, 1916, and did not make a complete recovery. In June, 1917, following a shrapnel wound in the back, patient suffered from severe pains in the loins which prevented him from walking erect. He was boarded in 1922, when he complained of rheumatism in the loin muscles and an inability to walk any distance. For a few months prior to admission patient had several transient attacks of an apoplectiform nature, during which speech and movements of the right side of the body were lost. These seizures lasted, on an average, about an hour, and after them he became emotional and depressed. The present mental illness commenced during March, 1923, when he became absent-minded and talked about going on the stage to earn his fortune as a vocalist. On admission patient was excited, hilarious, and deluded. Orientation for time and place appeared normal, but there was a slight degree of anterograde amnesia.

Central Nervous System.—The pupils were slightly unequal and irregular; reactions to light and the responses to accommodation and convergence were all brisk and equal. The oculo-spinal reflexes were present and the pupils oscillated at rest. Speech was indistinct, tremulous, and slurred, articulation being accompanied by tremors of the labial and lingual muscles. The right knee-jerk was diminished, but the left was absent. Tendo-Achilles jerks were absent on both sides. The superficial reflexes were present and equal. Gait was normal, and the tests for the loss of deep sensibility were negative.

Serology.—C.S.F.: colloidal gold 0023332000; colloidal gamboge 222110; globulin one plus; cells 60 per c.mm.; W.R. positive. Blood: W.R. positive 1 in 3 dilution.

The combination of clinical signs suggesting general paralysis and a "luetic" curve of the gold-sol test of the cerebro-spinal fluid induced us to label the case as one of syphilitic meningo-encephalitis.

Treatment by "914" and silver salvarsan was commenced in October and continued till May 13th, 1924, when a total dosage of 0·75 g. of "914," 1·35 g. of silver salvarsan, and 8 gr. of mercuric salicylate had been given. During treatment patient said he felt much better, although the inoculations were attended or immediately followed by rigors, headaches, or attacks of vomiting. He improved mentally, became quiet, amenable to reason, and more affectionate towards his wife. On three occasions during the course he suffered from apoplectiform seizures, ushered in by intense vertigo and headaches, and followed by great mental confusion, aphasia, and hemiplegia. The attacks followed at irregular intervals and were accompanied by a rise in temperature (101° F.) which lasted several days. Examinations of the cerebro-spinal fluid during the attack showed no alteration in the cell count, although following the second seizure the "luetic" of the gold-sol test was converted into a typical "paretic" curve (5553210000). As a remittent fever of 100° F. continued with loss in weight and appetite, treatment by tryparsamide was substituted, and the first injections were duly given on May 20th, 1924. A course of eight inoculations was administered, and an immediate and pronounced improvement was observed. He so quickly recovered his strength and improved in general health and body-weight that he was able to walk about steadily and do useful work in the wards. The apoplectiform seizures ceased, while his speech improved. The inoculation reactions that frequently followed the salvarsan injections did not reappear with the tryparsamide treatment. Excellent progress was maintained during the rest interval. He took a great interest in himself and appreciated the special treatment that was being given to him. The improvement, however, was temporary, as from the commencement of the second course on Sept. 16th, 1924, patient gradually became worse, so that by the end of the fifth dose he was neither able to talk nor to move any of his limbs. An aphasic attack was less pronounced, and not accompanied by pyrexia or intense headaches. During the few days that followed patient became depressed and agitated. He gradually got worse, and one day made an attempt on his life. Washing and feeding became increasingly difficult, and as his sleep was disturbed, hypnotics were freely administered. A neuro-relapse was suspected, and in the hope of cutting short the complications two-weekly doses, each consisting of 4·5 g. of tryparsamide and 1 gr. of mercuric salicylate, were given. An epileptiform seizure occurred four days after the first of these inoculations, and as the mental and physical condition became steadily worse treatment was stopped. At the time of writing his physical condition shows a slight change for the better, but his mental state shows no signs of recovery. The present serological readings are:—C.S.F.: gold-sol 0011100000; colloidal gamboge 100000; cells 2 per c.mm; globulin trace; W.R. positive. The blood W.R. is doubtful.

CLASS D.—*Miscellaneous Cases.*

An opportunity for testing the efficacy of tryparsamide in the treatment of non-syphilitic nervous states occurred on the admission of a case of post-encephalitic confusion and a case of Huntington's chorea. A short course of five weekly doses were given to the latter, but as no improvement took place beyond an increase of 17 lb. in body-weight, treatment was discontinued. The treatment of the former is of interest because of the effect of the drug on the serological findings.

CASE 19.—B. E., male, aged 35; fisherman; admitted June 2nd, 1924.

History.—In March, 1924, patient had encephalitis lethargica with alternating periods of delirium and somnolence. Recovery was incomplete, and a complete change in character took place. He became childish and simple and paramnesia was marked. Certification became necessary when he tried to drown himself and later to strangle his wife. He had been a heavy spirit drinker for many years.

On admission he was suffering from extreme confusion with hallucinations. His bodily health and condition were good.

Central Nervous System.—The pupils were irregular and markedly unequal; reactions to light and to convergence and accommodation were sluggish, but showed a fair excursion. Pupillary oscillations were absent, and the sympathetic reflexes were present, but sluggish. Attacks of transient diplopia were frequent, but no weakness of any extrinsic muscles of the eye as revealed by ordinary examina-

tion. The deep reflexes of the lower limbs were normal, but those of the arms were slightly increased. The epigastric reflexes were not elicited, but the remainder were normal. Fine intention tremors were observed in the protruded tongue and the outstretched hands. The facial expression was atonic, but the folds remained well marked. Speech was difficult but effective, without evident tremors of the facial muscles. The general sensations, sphincters, and gait appeared normal. Choreiform movements of the limbs were absent and coördination generally was good.

Serology.—C.S.F.: colloidal gold 0023321000; colloidal gamboge 121110; globulin one plus; cells 256·3 small and large lymphocytes per c.mm.; sugar 0·057 per cent.; W.R. negative. Blood: W.R. was weakly positive in 1 in 8 dilution.

The spinal fluid W.R. was repeatedly tested and was negative. From June to August patient was apathetic and completely indifferent to his environment. Outbursts of causeless crying were frequent. On two occasions he had for several days what I assume to be a mild recurrence of his encephalitic condition as he became drowsy during the day and required to be awakened at meal hours. These clinical relapses were accompanied by mild fever, never rising above 100° F.; 5 c.cm. of cerebro-spinal fluid were withdrawn on August 11th, 1924, and immediately administered intravenously, but with no good results, so a trial with tryparsamide was suggested. The serological readings immediately prior to the commencement of treatment by tryparsamide were:—C.S.F.: colloidal gold 555432100; colloidal gamboge 222100; globulin one plus; cells 96·6 small and large lymphocytes per c.mm; sugar 0·05 per cent.; W.R. negative.

A course of ten weekly doses of 3 g. of the drug was given, and at the end of the period patient showed a remarkable improvement, especially in his general health and body-weight. (At the time of writing body-weight has shown a gain of 21 lb.) His mental state has improved slightly. He takes more interest in his environment, takes his food more readily, and has adopted cleaner personal habits. A second course of tryparsamide injections has been instituted in the hope of further improvement in his mental state. Serology prior to the commencement of the second course reads:—C.S.F.: colloidal gold 000110000; colloidal gamboge 110000; globulin trace; cells 18·3 per c.mm.; sugar 0·064 per cent.; W.R. negative. The blood W.R. is weakly positive in a 1 in 5 dilution; the sugar content 0·08 per cent.

Serological Findings.

Since malarial therapy had produced serological changes in the cases of general paralysis of Class B prior to the institution of further treatment by tryparsamide, and as Class A consisted of cases of a similar nature, but treated only by the drug, it was possible to contrast the respective serological merits of both methods of treatment, and to form some opinion of the efficacy of tryparsamide as an additional therapeutic agent in the fever-treated cases. Serological improvement of varying degrees was manifested in all the cases of general paralysis treated by tryparsamide.

The effect on the cell count was particularly striking. A marked reduction in the number of lymphocytes was observed in all the cases where a lumbar puncture was performed after the sixth injection, and at the end of treatment this improvement was manifested in 100 per cent. of the series. The final average readings were low, 50 per cent. of the fluids having a cell count ranging from 0 to 5 c.mm., 25 per cent. from 5 to 10 per c.mm., and 25 per cent. from 10 to 20 cells per c.mm. The decrease in the number of cells was general, as no increase in lymphocytes was observed. The globulin content, as estimated by the ring test of Ross-Jones and the reaction of Pandy, was reduced in amount at the end of treatment in 62·5 per cent. of the cases, but remained unchanged in 37·5 per cent. of the series.

The W.R. of the cerebro-spinal fluid has been very refractory to treatment with tryparsamide, no fewer than six out of the eight fluids showing "no change." A negative reaction, however, was obtained in the remaining two, or 25 per cent. of the cases.

The colloidal gold curve showed slight changes in several cases at the end of the first course of treatment. A mid-zone or "luetic" curve was obtained in two instances after six and eight doses respectively. Prolonged treatment with two or more courses of tryparsamide was permitted in three cases, when a variety of changes in the curve was observed. A slight change occurred in one, a "sub-luetic" curve was obtained in the second, while in the third a negative gold solution resulted. The colloidal gamboge reaction exhibited parallel changes to those noted in the gold-sol test at the different stages of treatment. The sugar content of the cerebro-spinal fluid of the whole series of general paralytics varied from 0·045 per cent. to 0·118 per cent. with an average of 0·068 per cent. before treatment. Following treatment the results varied in individual cases from 0·059 per cent. to 0·10 per cent. with an average of 0·071 per cent. Simultaneous blood-sugar estimations were made. The W.R. of the blood tended to be affected at the early stage of treatment. At the close two, or 25 per cent., became negative; three, or 37·5 per cent., were definitely reduced in intensity, and a similar number remained unchanged.

A reference to the cases grouped under Class B will demonstrate that malarial treatment in cases of general paralysis produces changes in the serological readings which more or less correspond to those obtained where tryparsamide alone has been used, except that the latter drug has perhaps a more pronounced effect on the cell count of the cerebro-spinal fluid. The employment of tryparsamide as an adjuvant to the malarial treatment of cases of paresis has not been attended by any brilliant results, although in two cases a more satisfactory serological reading was obtained after the drug was used.

In the meningo-vascular group the periods of observation have been short, but long enough to note that changes tending to the normal have occurred in the constituents of the blood and spinal fluid of all the cases. In the treatment of one patient the superiority of tryparsamide over other arsenicals has been demonstrated.

Reactions following the Administration of Tryparsamide.

The reactions following tryparsamide may be classified as (1) Early effects: (*a*) those occurring during or immediately following the injection; (*b*) those occurring within 24 hours of the injection. (2) Late effects.

(1) *Early Effects.*

(*a*) Those occurring during or immediately following the injection.

1. *Vasomotor Symptoms.*—"Anaphylactoid" or "nitritoid" crises occurred on five successive occasions during the treatment of one case (Case 14). The phenomena, however, did not make their appearance or cause any discomfort to the patient until immediately after the fifth injection, when he complained of sickness. The attack was transient. The symptoms were more marked after the next injection, when he complained of a "lump" in his throat and of faintness. This attack lasted a little longer (from 5 to 8 seconds) and then disappeared. During the seventh inoculation the arsenical salt was administered more slowly, but the moment the needle was withdrawn from the vein the patient complained of sickness and a feeling of intense oppression in the chest, while the face became flushed and his breathing laboured. Before the eighth and ninth inoculations a prophylactic of 1 c.cm. of a 1 in 1000 solution of adrenalin chloride was given intramuscularly, and the only symptom noted was a transient attack of nausea. At the tenth injection no prophylactic was given, and the operation was followed by no abnormal symptoms. Again, following two subsequent injections after an interval of eight weeks, no alarming symptoms made their appearance. Observations on the pulse readings during these crises revealed no changes in rate or volume. The attacks were mild in degree, never lasting more than a few seconds, and recovery was prompt and rapid. It might be interesting to point out that the patient had never been susceptible to any form of vasomotor disturbances or idiosyncrasies prior to treatment, nor did he present the so-called "plethoric disposition," in which these phenomena are said to occur. His heart, however, was enlarged in its transverse axis, and auscultation revealed a regurgitant mitral lesion.

Before treatment he suffered from attacks of palpitation and shortness of breath on exertion.

(*b*) Those occurring within 24 hours of the injection.

1. *Rigor, Rise of Temperature, and Headache* were the commonest sequelæ, and usually appeared within one hour, passing off by the third day. One mild rigor occurred during the night following the first inoculation of Case 10. The rise of temperature often occurred on the same evening as the first injection or on the evening following and only occasionally after the second injection. The average rise of temperature was no more than a degree Fahrenheit, although on three occasions temperatures of over 100° F. were recorded. Slight headaches, frontal or occipital, were common reactions to the first and occasionally to the second injections.

2. *Diarrhœa and Vomiting*, which were usually slight, occurred only in some of the cases which received combined arsenical and mercury treatment. In all except one the disturbances were mild, and passed off without treatment, the diarrhœa being limited to one or two semi-solid dark green offensive motions, and the vomiting to little more than retching. Streaks of bright red blood and mucus were observed in a few of the examined stools following the first injection, and were as often as not found in cases where diarrhœa was absent. In one patient it was not until the twenty-third injection that blood and mucus made their appearances. These symptoms never recurred with continued administration, and therefore no alterations in dosage or times of administration were required. In Case 13, however, the symptoms were more severe and considerably exhausted the patient. In the early morning following the first injection he complained of feeling unwell, and suffered from tenesmus, diarrhœa, and vomiting. The motions were numerous, diffluent, green, and very offensive. No mucus or blood was present. Vomiting of stomach contents tinged with bile came on later and persisted throughout the morning and early afternoon. The appetite was lost and inconstant pains in the abdomen and head accompanied the attack. On the exhibition of alkalis by mouth the attack was quickly brought under control and disappeared before nightfall.

3. *Conjunctivitis.*—Injection of the palpebral conjunctivæ occurred in three of the advanced cases following the second, fifth, and sixth doses respectively. The inflammation was subacute and accompanied by slight muco-purulent discharge. In two cases it appeared after the last dose had been given.

4. *Shedding of the Nails.*—This unusual condition was seen in one patient soon after the first inoculation. Within three to four weeks most of the nails had been affected, and by the end of the course (ten weeks) all had been shed and partially replaced.

5. *Mental Symptoms.*—Intense restlessness with insomnia and delirium occasionally followed the administration of the early doses in a few of the cases of the bedridden type. The attacks varied in duration from 12 hours to a few days.

Treatment.—For the vasomotor disturbances intramuscular injections of 1 c.cm. of 1 in 1000 adrenalin chloride were found to be beneficial.

(2) *Late Effects.*

1. *Pathologic Urinary Constituents.* — Traces of albumen were relatively uncommon. In each instance the urine secreted in the early morning of the day following the injection was collected and examined. A trace of sugar (phenyl-hydrazine test positive) was found on one occasion in Case 13 after the administration of the first dose of arsenic. Examinations made following the later injections were all negative. Bile was present in two cases affected with jaundice.

2. *Malaise.*—A general feeling of malaise occurred late in the second course of one case (Case 10), and was considered a sign of intolerance. It was accompanied by headache, loss of appetite, lassitude, and loss of weight. After a rest interval of ten weeks tryparsamide alone was tried with encouraging results. The patient's appetite and weight steadily improved, and now, at the end of the third course, he is very fit and well.

3. *Jaundice.*—Jaundice as a late symptom occurred in two cases of the series (Cases 13 and 15). Whereas the former received a complete course of ten doses the latter had five inoculations, or half the prescribed course of combined arsenic and mercury treatment. This was due to the development of seizures after the fifth injection. The first symptoms of jaundice came on in both cases during a rest interval, six and eight weeks respectively, after the administrations of the last doses. The onset, clinical signs and symptoms, blood changes, course and duration of the malady were remarkably similar in the two cases, and both patients made a rapid and uninterrupted recovery. There were no prodromal nor premonitory signs as the patients were in good health when the tinging of the conjunctivæ was noted. The clinical signs and symptoms were like those in a mild attack of catarrhal jaundice. The fæces were slate-grey and offensive. The urine contained bile-pigment.

Examinations of the blood showed :—

Blood serum, tinged highly yellow.
Fouchet test, strongly positive.
Gmelin test, strongly positive.
Van den Bergh test, delayed positive in phase 1; immediate positive in phase 2.
Sugar content, 0·09 per cent. and 0·10 per cent. (Cases 15 and 13 respectively).
Lipase estimation, 0·5 and 0·6 respectively.

The results of the lipase test suggested an arsenical affection of the liver cells with impairment of function. Ordinary diet and alkalies were prescribed and recovery was prompt and rapid. No clinical recurrences have been observed up to the time of writing, although in Case 15 the blood serum still gives a slightly positive Fouchet reaction (i.e., ? latent jaundice).

4. *Epileptiform seizures* developed half-way through the first course of Case 15, who became weak and exhausted after nine rigors. Quinine therapy was instituted until malarial parasites had disappeared from the peripheral circulation. He received his first doses of tryparsamide and mercury three days later and the injections were continued at weekly intervals for a month, during which time he improved in health and weight to the extent of 5 lb. A change, however, was noted four days after the administration of the fifth dose, when he became restless and confused. During the following 24 hours he exhibited signs of meningeal irritation with conjugate deviation of head and eyes to the right, rigidity of limbs, and grinding of teeth. The temperature steadily rose and by the evening of the following day had reached 104·2° F. At this stage twitchings of the muscles of both forearms and the right half of the face made their appearance. Patient was now unconscious and lay in bed on his right side in a state of flexion. Cerebro-spinal fluid was withdrawn under considerable pressure and no *Spirochæta pallida* were found. On the morning of August 19th, the third day of his illness, epileptiform seizures appeared and followed each other rapidly, culminating in a condition of status epilepticus. Within 16 hours patient had had 77 seizures which left him extremely exhausted. He rallied, however, and at the end of a week began to show signs of improvement. Jaundice occurred six weeks later, but the malady was tolerated without much discomfort. He has steadily improved in health and at present is up and about, apparently none the worse. Seizures have been regarded as a contra-indication to further treatment.

5. *Visual Disturbances.*—Among the 20 patients who have received more than 240 injections of tryparsamide, 4, or 20 per cent., have complained of dimness of vision. All were neuro-syphilitics and had received in addition intramuscular injections of mercury. In three the impairment was slight and cleared up when treatment was stopped. In one, an advanced bedridden patient, slight permanent visual defect remained. The symptoms made their initial appearances early in the course of treatment, although on one occasion no complaint was made until after the

second injection of the second course (the twelfth injection). The times of onset in the remaining three cases were from 12 to 48 hours following the sixth (twice) and ninth injections respectively.

6. *Local Reactions at the Seat of Inoculation.*—Twenty injections were given by the subcutaneous route; in one case on 11 successive occasions. No immediate or late reactions in the neighbourhood of the injection were observed.

Effect on Nutrition.

A striking feature of tryparsamide therapy was the remarkable effect of the drug on the state of nutrition. In the majority of cases a marked improvement in general health and increase of body-weight were recorded. The tonic effect of the drug was established and its value might be exploited in certain other diseases characterised by a general failure of nutrition.

Weekly weight records were kept and the chart below illustrates three varieties of response in body-weight that have occurred during the periods of treatment and drug-free intervals. At the end of the first course (eight to ten doses) of treatment a gain in weight was noted in 17 patients, or 85 per cent. of the series. The increase ranged from 1½ to 34 lb., or an average of a little over 7½ lb. for the series. A loss in weight took place in three cases, or 15 per cent., ranging from 1 to 9 lb., with an average of 5½ lb. The latter were all cases of advanced general paralysis, two of which rapidly deteriorated under treatment and died.

The increase or loss in weight, however, was not always sustained during the intervals or in the succeeding courses of injections. In no fewer than 29·4 per cent., where a pronounced increase had taken place during the first course, a loss occurred during the interval that followed. A gradual increase approached higher levels in 59 per cent. of the cases. Figures relevant beyond his stage are difficult to give as only two cases, or 11·1 per cent., of the series received three full courses of drug treatment, but it may be stated that on the whole the drug exercised a pronounced tonic effect on all the cases which were not affected by any serious complications during the period in which they were under observation.

I beg to acknowledge my indebtedness to Dr. R. M. Clark, medical superintendent of the institution, for permission to place on record the results of these investigations. The Wassermann reactions of the blood and spinal fluid were carried out at the Public Health Laboratory under the direction of Prof. W. W. C. Topley.

A NOTE ON THE TREATMENT OF GENERAL PARALYSIS BY TRYPARSAMIDE.

BY M. BROWN, M.B., CH.B. GLASG.,
PATHOLOGIST, GARTLOCH MENTAL HOSPITAL;
AND
A. R. MARTIN, M.B., B.CH., B.A.O. BELF., D.P.M. LOND.,
ASSISTANT MEDICAL OFFICER TO THE HOSPITAL.

FOLLOWING reports on the undoubted efficacy of tryparsamide in cases of African sleeping sickness, this drug was advocated in the treatment of neurosyphilis, particularly general paralysis. The world-wide interest in the malarial treatment of the latter disease tended to divert attention from the arsenical compounds, but there are signs of a return to what appears to be the more rational method of treatment. In a recent address to the Liverpool Medical Association, Prof. Warrington Yorke said that the future successful treatment of general paralysis probably depends on tryparsamide or an allied drug. Difficulty in obtaining the drug has restricted investigation in this country, but extensive work is now being carried out in various hospitals. The results obtained here may prove interesting.

The Selected Cases.

In all, 17 cases of general paralysis were placed under treatment. We regarded as general paralytics those cases which, in addition to the usual physical and mental signs, gave the following readings on examination of the cerebro-spinal fluid; (1) Wassermann positive with 0·1 c.cm. fluid; (2) a paretic colloidal gold curve; (3) positive Ross Jones and Pandy tests; and (4) marked lymphocytosis. We also regarded a strongly positive serum Wassermann as additional evidence, as it is only very rarely that the blood in paresis gives a negative reaction. Although contraindicated by some authorities we included, in the 17, patients in all stages of the disease and three bed cases showing marked mental and physical deterioration.

We commenced in October, 1925, with six 1 g. doses of tryparsamide given at weekly intervals, 15 cases were treated by the intravenous route and 2 intramuscularly. During this period one patient was transferred to another hospital and one patient died. The latter had been regarded as a slowly dementing paretic of the simple facile type. He had been here for three years, his physical condition was good, and he showed only slight mental deterioration. He had no toxic symptoms whatever, but a week after his sixth injection he complained of feeling unwell. He developed a marked rise in temperature, followed by severe congestive seizures, and died within a few days. Post-mortem examination showed typical brain changes with marked congestion, but there was no excess cerebro-spinal fluid and no spirochætes could be found by dark-ground microscopy. The liver, kidneys, and spleen were somewhat congested, but otherwise normal.

During this preliminary course of treatment there were no toxic disturbances, eye complications, excitability, or other ill-effects, even among the bed cases. Accordingly we decided to increase the dose. Each patient now received eight 2 g. injections at weekly intervals half to one hour after the mid-day meal. *No other drug was administered in conjunction with the tryparsamide, as we did not wish to obscure any results that might be forthcoming.* For the same reason no alteration was made in the diet or environment of the patients during the treatment. Two deaths occurred before the course was completed, and in both instances patients were of the slowly dementing apathetic type; one was more advanced than the other and confined to bed. Death was similar to that mentioned above and followed a

period of severe congestive seizures accompanied by pyrexia. Post-morten examination was refused in one case and in the other the post-mortem findings were quite typical and there were no liver changes. The form of paresis present in these cases nearly always proves to be the most progressive, most resistive, and the least liable to undergo remission, whereas it is the expansive, active, megalomanic type which provides the greater number of stationary and protracted forms, and appears to be less resistive. Our subsequent results bear this out to a certain extent.

The number of cases now under observation was limited to 13. After conclusion of the treatment we allowed two months to elapse and then carried out further clinical laboratory investigations.

Clinical Findings.

Of the 13 cases only 2 failed to benefit. Improvement first showed itself during the months of January and February, and in all cases this improvement has held up to the present time of writing. Speech, tremors, and gait all improved, more especially the latter, and this was one of the first changes to be manifested. Argyll Robertson pupils, where present, were unaffected. Five cases, all steady and useful workers, have shown marked remission of mental and physical symptoms and are exceptionally well; three of them have been granted parole and the other two are being discharged to care of friends. Three cases previously unemployable and inclined to be dull, listless, and foolish, are now willing workers with some degree of initiative. Two bed cases recovered sufficiently to be up, and are capable of doing light ward work. One paretic of four years' standing has remained stationary mentally, but is improving physically. One case showed no change whatever. In the thirteenth case, a taboparetic with an alcoholic history, the physical condition gradually became worse. He developed bladder complications and broncho-pneumonia, and died two months after the course was finished. Throughout he was wonderfully clear mentally. Post mortem showed nothing of particular interest. Changes were most marked in the expansive type of paretic, and in the depressed, agitated type; the slowly dementing, facile, and apathetic form showed least change. There were no toxic disturbances of any kind and all except two of the patients gained weight.

Laboratory Findings.

Tests were carried out on the blood-serum and cerebro-spinal fluid of 13 cases of general paralysis before and after treatmnt by tryparsamide. In over 50 per cent. of the cases alterations took place in the colloidal gold curve and in the Wassermann reaction. The paretic curve showed a tendency to disappear with complete absence in four cases, while the Wassermann raction in both cerebro-spinal fluid and blood-serum showed a tendency to become weaker. These changes were most marked in those expensive and active paretics who had undergone such marked mental and physical improvement. In six cases the laboratory and clinical findings closely coincided.

Conclusion.

In dealing with the treatment of general paralysis there are certain factors always to be borne in mind which tend to obscure results and lead to misinterpretation. These are: (1) the possible tonic effect of arsenic, resulting in temporary improvement; (2) the beneficial effect of arsenic in certain meningeal complications which frequently accompany paresis; (3) the possibility of paretic blood-serum and cerebro-spinal fluid undergoing independent and marked variation; (4) the tendency to remissions.

Taking these facts into consideration, and in view of the limited number of cases which we had under observation, it is extremely difficult to come to any definite conclusion. As, however, only one course of treatment has been tried, and as the improvement which took place in the majority of cases has continued for about six months, we consider these clinical results, together with the coincidental laboratory findings, of sufficient import to justify further investigations along similar lines. When it is remembered that the successful treatment of ordinary syphilis by arsenic can only be brought about after a three years' course, it would appear, in view of the above results, that prolonged administration of tryparsamide in general paralysis is at least worthy of trial, particularly in the megalomanic forms.

It is a drug of low toxicity, readily soluble, and very easy to administer. That it has penetrating power is more or less confirmed by the astonishing results obtained in African sleeping sickness. The supplies used were manufactured by May and Baker, Ltd., by arrangement with the Rockefeller Institute.

Permission to carry out these investigations was granted by Dr. A. M. Dryden, the medical superintendent.

PORADENITIS, OR SUBACUTE LYMPHOGRANULOMATOSIS.

BY A. T. TODD, M.B. EDIN., M.R.C.P. LOND.,
DEMONSTRATOR OF PATHOLOGY, UNIVERSITY OF BRISTOL; HON. ASSISTANT PHYSICIAN, BRISTOL ROYAL INFIRMARY.

THE following account of this condition, together with a description of two cases, may prove of interest. The disease, though uncommon, appears to be spreading, and unless it be kept in mind difficulty may occur in distinguishing it from conditions which have a different prognosis and require other treatment. It is possible that some of these cases are being classified as tuberculous adenitis, chronic lymphadenitis, syphilis, or lymphadenoma, but although there are resemblances there should be no difficulty in the separation of these cases.

The apparent increase of the disease may be due to greater accuracy in diagnosis. About 50 cases have been recorded in the foreign literature of the last two years. It has certainly become more common since the war, and it is possible that this is due to its transport by French colonial troops. As will be seen below, my first case contracted the disease in Africa.

Several names have been given to the disease. Most commonly it is termed subacute inguinal lymphogranulomatosis; an objection to this name is supplied by the fact that in my first case the glandular distribution was cervico-brachial, and other cases with a similar regional incidence appear to have occurred.[4] Moreover, the name lymphogranulomatosis is commonly applied to lymphadenoma in America and Germany. The French term, "poradenite," has much to be said for it; the appearance of the spongy semi-necrotic gland in its last stage deserves this name. It has also been called the fourth venereal disease.

Symptoms and Course.

The virus obtains entry through the genital mucosa in the majority of cases; in Case 1, however, it appears to have entered by the buccal mucosa. The incubation period would appear to be about three weeks. A small, easily missed herpetoid lesion, or a small papule is produced at the site of inoculation. A slow, painless enlargement of the regional lymph glands is noted about three weeks later. These are hard and not fixed at first; softening and matting occur later. Gradual enlargement proceeds for weeks or months, and then softening in one or more of the glands is observed. The softening is not accompanied by any marked appearance of inflammation. The softened gland, if untreated, slowly erupts through the skin, leaving sinuses which are slow to heal and prone to secondary pyogenic infection.

Symptoms are few apart from the glandular swellings. Pain is slight or absent, unless a nerve happens to be pressed upon. The gland is occasion-

ally tender, but this is not the rule. A degree of anæmia is found—this may explain the vague malaise which is experienced. Case 1 complained of pruritus, and it will be remembered that this symptom also occurs in lymphadenoma, but in a person just returned from the tropics pruritus must not obtain too much attention. There is a polymorph leucocytosis of mild degree in the early stages.

Progress is variable but slow, the disease lasting for months. No data are yet available as to the ease of infectivity and the risks of non-venereal infection.

Pathological Features.

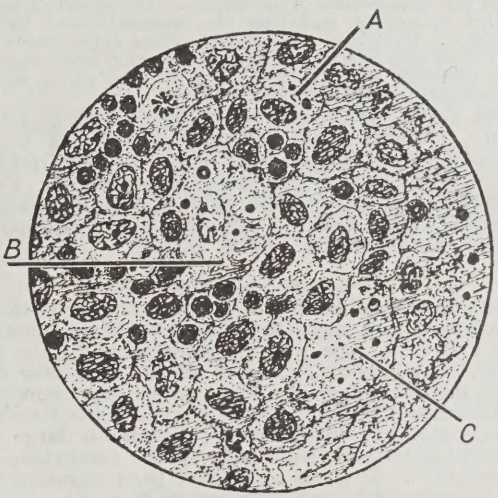
The entry of the virus causes an early proliferation of the lymph and plasma cells at the site of invasion—i.e., usually at the periphery of the gland. This change is followed by a much more massive proliferation of the endothelial cells of the reticulum. A nodule composed almost entirely of large cells very similar to the epithelioid cells of a tubercle is formed. These cells occasionally show two nuclei, and, owing to the rapidity of their proliferation, they commonly show mitotic figures. This is a point of some diagnostic importance; mitotic figures are not so frequent in other gland enlargements, neoplasm excepted. The frequency of mitoses is variable, however; Gamna[1] says that they are always very numerous, but Favre[2] takes objection to this. The probability is that both are right; in Case 1 the gland, in relatively early stage, shows many mitoses, but in the later stage, found in Case 2, mitotic figures can be found only on prolonged search.

The nodule of endothelium subsequently shows degeneration and colliquative necrosis, the centre being first affected. At the periphery proliferation progresses steadily, and the gland is slowly permeated by the newly-formed tissue which contains small foci of fluid, the appearance being well likened to that of a sponge. Other cells play a less important part. Polymorph leucocytes are fairly numerous, rather more than in a tubercle. Fibroblasts are little stimulated until the necrotic fluid is discharged, then they play a part in repair. Granular cells are moderately numerous, but are mainly basophil; eosinophil cells are scanty, a point of importance in the differential diagnosis from lymphadenoma. The vessels are little affected, there is a patchy congestion, and here and there œdema and some lymph stasis can be seen.

This description would have sufficed until about a year ago; then at about the same time and independently Gamna and Favre described a new feature, the presence of intracellular inclusions, which the former observer considered to be a protozoon and the causal virus; this view now meets with general acceptance. Some of the large endothelial cells can be seen to contain small globoid bodies varying between one and three micra in size. They readily take any nuclear stain, and, except for their larger size, they recall the appearance of the "encephalocytozoon" of encephalitis lethargica; like the latter, a clear halo is often to be seen surrounding them, but they stain much more readily. I find that they show a special affinity for well-matured methylene-blue; this stains them a deep blue-black colour, allowing them to be picked out from their surroundings readily. The chromophilic material is not evenly dispersed through the globoid, at any rate in the larger ones; in these it is sometimes collected into a denser peripheral layer and then recalls the appearance of an erythrocyte, staining and size excepted, or there is an accumulation in a horseshoe-shaped mass at one pole. In my two cases there was no hint of any acidophil substance in the bodies, and Favre does not find any; Gamna has described the presence of faintly staining acidophil areas, but there is nothing suggestive of the strongly acidophil structures of the malaria and Leishman parasites (see figure).

The nucleus of the containing cell stains well at first; it loses its staining properties later and cannot be made out. The parasites are then found first in the cell membrane and later are found extracellularly in between the healthy-looking cells and also amongst the necrotic débris in the centre of the nodule. The distribution of the parasite appears to be variable, however, for Gamna finds them to be scanty in the older parts of the lesion, while Favre notes that they are readily to be found in this position. In both my cases parasites are numerous, in the spreading margin and necrotic areas alike. The same parasite has been found in the primary lesion,[2] which resembles the glandular condition in type and termination of cell change.

The disease can be transmitted to guinea-pigs by inoculation of the necrotic fluid, but this fluid after



Semi-schematic drawing of lesion. Necrosis occurring to the right. At *A* is a cell with well-preserved nucleus containing parasites; at *B* a cell with degenerating nucleus containing parasites; at *C* the nucleus has disappeared.

filtration through the finer Berkefeld candles is no longer infective. Attempts to cultivate the organism have so far failed with all media.[1]

Clinical Records.

CASE 1.—Male, aged 32, has resided in Nigeria for about two years; health good except for mild malaria and what was diagnosed "low fever." He came to Mr. H. Chitty's out-patient department, and Mr. Chitty kindly transferred him to me for investigation. For about a year he has noticed swellings about the neck and arms, which gave little trouble unless knocked. He does not feel well and he easily tires. On careful questioning he admits that his skin has been troublesome lately—various parts itch without there being anything to be seen. Just before he was sent back to England the large epitrochlear gland of the right arm became soft and was removed; a diagnosis of "suppuration" was made.

Examination was disappointing except for the glandular swellings; these were left submaxillary, axillary less marked, cervical, especially a gland of the low cervical group on the right side; the latter was about the size of a small walnut. The glands were tender on firm pressure and were readily movable. The inguinal glands were little enlarged, perhaps more than the average for an adult, but to nothing like the size of the glands noted above. The spleen was just palpable. There was no scar to be found on the genital mucosa. The possibility of any venereal disease was denied.

Blood showed 80 per cent. hæmoglobin. Films showed well-formed erythrocytes with little more than the normal anisocytosis and no polychromasia. There were no malarial parasites to be seen. Polymorphs, 56·0; small lymphos., 24·6; large lymphos., 13·6; transitional, 3·0; eosinophils, 2·6; mast, 0·2 per cent. No abnormal types were found. The Wassermann reaction was positive; the tubercle complement fixation was strongly positive. The large cervical gland was punctured and films were stained by Giemsa and Leishman's methods. These showed a few eosinophil cells, few lymphoid cells for a lymph gland, and there were many large cells with palely staining nuclei. Amongst the latter some much larger cells were observed to contain small basophil bodies; I thought that these were Leishman bodies at first, but altered my opinion on finding that there was no acidophil structure present.

The patient was put on liq. arsenici hydrochlor. while the condition was being investigated, as a provisional

diagnosis of lymphadenoma had been made. He responded rapidly to this, and shortly reported that he felt stronger and that the glands were shrinking. As I was not satisfied with the diagnosis I had the largest gland excised; on section I found the appearances noted above. He continues to do well, and when last seen the largest gland was about the size of a haricot bean.

CASE 2.—For the clinical details of this case I have to thank Mr. Duncan Wood under whose care he was admitted to Cossham Hospital. The patient was a young adult male who has never been abroad. Contact was alleged in April, 1925, and the swelling was first noted in November. There was no penile scar. A single inguinal gland was enlarged to the size of a damson. No other swellings or symptoms were noted. Mr. Wood removed the gland for diagnosis and sent it to the department of pathology. He observed that it shelled out easily and that the wound healed by first intention. The gland presented the same appearances as in the former case except that necrosis was much more advanced. The parasites were numerous in all the parts, showing endothelial proliferation and necrosis.

The finding of a positive, more frequently a partially positive, Wassermann reaction appears to be not infrequent.[3] A cuti-reaction, using the material from the necrotic focus, has been practised by Frei [5]; eight cases of the disease gave a positive reaction; controls were negative. There was no complement fixation with this material as antigen.

Diagnosis and Treatment.

Diagnosis should be easy once the condition is remembered. A suspected gland should be punctured and a little of the pulp withdrawn and thin films made. These may be dried in air, or better fixed with methyl alcohol. Then stain one film with Leishman's stain and another with methylene-blue, counter-staining with eosin. Search for large cells containing blue bodies, firstly in the methylene-blue preparation. If these are found then compare with the Leishman film to determine whether there are any strongly stained red particles present. In the absence of the latter and of acid-fast bacilli the condition may be safely diagnosed poradenitis. It should be noted that in any necrotic gland small basophil bodies, fragments of pyknotic nuclei, are frequently to be found. If the features noted are not kept in mind a diagnosis of poradenitis will be made more often than is justified.

There are several treatments already. Excision was first practised, and in the early stages is radical. Radiotherapy has been given up, as it results in a massive fibrosis. The specific treatment is now emetine, with or without iodine. The former is given in daily dose of 1 gr. by the mouth, and is continued until 15 gr. have been given; a second or third course may be needed. Iodine has been given intravenously and by the mouth. Perorally it is best given as a 10 per cent. solution of iodine in 70 per cent. alcohol. Commencing with 10 drops in a little milk twice daily, the dose is slowly increased to 80 drops. I have given 200 drops of this strength of iodine, though not in this disease.[3] As is noted above, my case is doing well on arsenic. He takes ℥ iv. liq. arsenici hydrochlor., with ℥ xxv. acid hydrochlor. dil. p.c. t.d.s.

I have to thank Prof. I. Walker Hall for some advice and encouragement. The expenses of the research have been met by a grant from the Colston Research Fund.

ARTIFICIAL LIGHT AT KING'S COLLEGE HOSPITAL.—Last week the Stock Exchange Dramatic and Operatic Society presented a new helio-therapeutic department to this hospital. The apparatus consists of three carbon arc lamps around which eight or ten patients can sit, and a mercury-vapour lamp for ward and localised treatment. The department was unlocked with a gold key by Mr. Archibald Campbell, the chairman of the Stock Exchange.

RESULTS OF THORACOPLASTY IN PHTHISIS.

BY J. GRAVESEN, M.D.,
MEDICAL SUPERINTENDENT, VEJLEFJORD SANATORIUM, DENMARK.

THE question raised by a study of the following statistics is whether various other possible operations should be adopted when artificial pneumothorax, partial or complete, turns out to be a failure on account of pleural adhesions. The claim for their adoption is based on the considerable number of patients upon whom, at this sanatorium, such operations have been performed during the last ten years. They have been followed up by regular inquiries after leaving the sanatorium, and in this way it has been possible to obtain a fair idea both of temporary and permanent results.

TABLE I.—*Thoracoplasty performed in 157 Cases of Pulmonary Tuberculosis. Results of 151 Cases Discharged from Sanatorium.*

Not yet discharged: 6 patients. Death caused by the operation in 12 cases = operation mortality of 7·6 per cent.

36 discharged as much improved 67 „ „ improved	} 103 (68·2 %)	
21 „ „ stationary or worse 27 „ „ dead	} 48 (31·8 %)	

Of the 151 discharged patients 150 had T.B. in sputum before operation.

T.B. disappeared on discharge in 52 cases (34·7 %)
„ still found „ „ 98 „ (65·3 %)

Up to March, 1926, thoracoplasty has been performed in this sanatorium in 157 cases. The temporary results are collected in Table I., from which it is seen that the operative mortality had been 7·6 per cent. The positive results are divided into two groups. Of these groups, "considerably improved" only contains those in which all symptoms have subsided, while "improved" contains those in which an undoubted improvement had taken place, so that the patients could walk about without fever, some of them also without T.B. in sputum, though with some symptoms of disease. All other cases are classified as "negative"; also those with a doubtful result, and those with a shorter time of improvement who failed again before discharge. According to this classification, the results on discharge of the 151 cases which had been discharged at the time the statistics were drawn up show a positive result in 68·2 per cent. a negative result in 31·8 per cent. T.B. in sputum had disappeared on discharge in 34·7 per cent.

A comparison of these results with other publications is shown on Table II., in which every endeavour has been made to ensure as uniform a classification

TABLE II.—*Comparative Thoracoplasty Results.*

—	No. of cases.	Operation mortality.	Excluded.	Positive results.	Negative results.
Alexander's compilation* of *all* cases published by authors from different countries.	1159	153 (13·2 %)	47 still under treatment. 28 unknown. } 75	664 (61·3 %)	420 (38·7 %)

Vejlefjord Sanatorium	157	12 (7·6 %)	6 still under treatment.	103 (68·2 %)	48 (31·8 %)

* Taken from the Surgery of Pulmonary Tuberculosis, by John Alexander, M.A., M.D., Lea and Fibiger, Philadelphia and New York, 1925.

† Taken from Die Chirurgische Behandlung der Lungentuberkulose, by Dr. Alfred Brunner, Johann Ambrosius Barth's Verlag, Leipzig, 1924.

as possible. The reason why our results are better than others is probably connected with the fact that all our patients have been operated on within the sanatorium (without any break in the sanatorium régime), combined with the fact that there is an experienced and technically well-equipped staff at hand to deal with these patients.

It may be of still greater interest to know how far the results can be expected to last. In the literature scarcely any statistics of the permanent results of thoracoplasty are to be found. The next table (III.)

TABLE III.—*Lasting Results of Thoracoplasty*

In 131 cases, discharged from sanatorium before March 1st, 1925. In March, 1926 (1–10 years after operation), the state of health of these 131 cases was :—

Fit for ordinary work	34	53 (40·5 %)
Fit for easier work	19	
Unfit for work		15 (11·5 %)
Death from tuberculosis (including operation deaths)		59 (45·0 %)
Death from other diseases		4 (3·0 %)

may therefore claim some special attention, as it shows the state of health of 131 patients whose discharge from the sanatorium took place more than one year before the statistics were made—i.e., one to ten years after operation. In these statistics are included all cases of death, inclusive of those dying as a direct result of the operation. It is seen that about *40 per cent. of the patients are able to work.* This figure can fairly be compared with the average permanent results of ordinary artificial pneumothorax. Out of the ten first cases (operated upon seven to ten years ago) seven patients declared themselves able to work. This example shows that the permanent results are distributed over the whole number of cases.

The fact that our patients at Vejlefjord Sanatorium are drawn chiefly from the well-to-do class must be borne in mind, but a study of many statistics shows that the results of artificial pneumothorax are much the same in both public and private sanatoriums, and it may therefore be anticipated that the same will hold good with regard to thoracoplasty. Moreover, the capacity of some of our patients has been very appreciable, many of them being fit for ordinary work such as clerks, farmers, pastors, and business men. Some of the patients have been through pregnancy and childbirth, and several of them are able to attend to ordinary house work.

From Table III. it is seen that the permanent results of thoracoplasty compare favourably with the results of artificial pneumothorax (A.P.). Naturally the percentage of capacity for work is higher in A.P. cases, if only the cases with complete A.P. without adhesions are considered. In these a permanently good result has been obtained by us in about 70 per cent. For several reasons a similar figure could not be expected among patients who show the indications for thoracoplasty. The simple fact that the disease in the former group has in no instance touched the pleura, whilst in the second group the pleura has in all cases been obliterated by adhesions, means a difference in the extent of the disease which must be taken into account. Moreover, the operative mortality in thoracoplasty and the different influences exerted by the operation upon the general condition of the patients must naturally detract from the good results compared with those of simple A.P. On the other hand, A.P. cases are so often handicapped by the presence of adhesions as to reduce the percentage of permanent cures by this method to an extent which allows thoracoplasty, in spite of its different dangers, to show a percentage of lasting cures equal to those of A.P.—namely, about 40 per cent.

In the tables no account has been taken of the extent of the rib-resections. The great majority of the patients in question have been treated with a *complete* thoracoplasty, leaving the one lung in a fully collapsed condition. In a minority the operation has been more or less partial. But in *all* cases the guiding principle has been to transform the chest into the shape which was thought to provide the best possible condition for an effective healing of the lesions.

In two of our cases the thoracoplasty was combined with the operation of apicolysis and transplantation of abdominal fat. In both of them this supplementary operation was indicated by the presence of a large apical cavity, and in both cases the additional apicolysis caused a final disappearance of bacilli. In seven of the cases the thoracoplasty was combined with phrenico-exeresis. This operation has, however, in certain quarters been recommended far more highly than, in our opinion, it deserves. As a matter of fact, we have not yet observed any case in which the phrenico-exeresis has afforded any additional benefit. Moreover, our results with thoracoplasty alone do not seem to us to need the very doubtful assistance supplied by phrenico-exeresis. Our experiments with this operation are being continued, and it remains to be seen if our opinion on this question will be changed.

In conclusion, we feel justified in considering the results of thoracoplasty well worth while the inconveniences involved therein, for undoubtedly it means a great improvement in the prospects of a group of patients whose outlook without the surgical treatment is extremely bad.

A NOTE ON THE ACTION OF GLYCERIC ALDEHYDE AND DIHYDROXYACETONE ON INSULIN HYPOGLYCÆMIA.

BY J. A. HEWITT, PH.D., D.SC.,
AND
H. G. REEVES, M.SC., PH.D.
(*From the Department of Physiology, King's College, London.*)

ONE of the most important reactions in animal metabolism is the breakdown of glucose with the production of heat and ultimate formation of carbon dioxide and water, but despite the fundamental nature of the reaction there is little precise knowledge of the mechanisms involved or even the intermediate substances produced. There are, however, grounds for assuming that lactic acid is one stage in the biological oxidation of glucose, and, admitting this, the more elusive problem is presented as to what is the precursor of the lactic acid. Though it is not proposed to enter into a chemical discussion here, it may be stated with some assurance that at least two substances intervene between glucose and lactic acid, and that one of these contains no asymmetric carbon atom—that is, is optically inactive.

The effect of administration to animals rendered hypoglycæmic by insulin of glucose, or its isomerides, fructose and mannose, is well known, but so far as the authors are aware no systematic investigation has been carried out on any possible analogous action of degradation products of these simple hexoses, especially those containing three carbon atoms and having close relationship to lactic acid.

For these and for other reasons a certain importance has been attached to the two initial oxidation products of glycerol—viz., the aldehyde, glyceric aldehyde and the ketone, dihydroxyacetone; and it is with one aspect of the relation of these to carbohydrate metabolism that the present communication is concerned —namely, their action on hypoglycæmia induced by insulin in normal animals.

The substances employed were pure synthetic crystalline preparations and uncontaminated with each other. Thus it was possible to investigate the effects of each independently—a result not obtainable when, as has been frequently done, the crude material formed by direct oxidation of glycerol, the so-called "glycerose," was used.

In the experiments here described, mice and rabbits were used and the routine technique was to render the animals hypoglycæmic by insulin, to await onset

of typical symptoms, and then to determine by subcutaneous injection the efficiency or otherwise of the aldehyde or the ketone. In each case suitable control experiments were conducted and when necessary to secure the survival of the animal, coma or convulsions were relieved by glucose.

It was found that no beneficial action of any note was displayed on mice or on rabbits when even massive doses of glyceric aldehyde were administered. In two mice an apparent partial transitory recovery was observed, but throughout the series of experiments in each case where glyceric aldehyde was tested recourse had to be made to glucose as antidote to the hypoglycæmia. Hence it was concluded that glyceric aldehyde is not capable of replacing glucose in relieving insulin convulsions.

With dihydroxyacetone a completely opposite action obtained in similar animals, and in view of the interest of this result two experiments are recorded, in one of which mice were used, in the other a rabbit.

Experiment A with Mice.

Six animals were injected at the same time, each with 5 minims of standard insulin (B.D.H., Ltd.) diluted to 1 in 25 with 0·05 per cent. hydrochloric acid. The animals whose average weight was 35·5 g. were kept warm.[1]

No. 1. After 59 minutes, convulsions; 6 minims aqueous dihydroxyacetone injected; gradual and complete recovery.

No. 2. After 60 minutes, convulsions; 6 minims aqueous glyceric aldehyde injected. At 78 minutes transitory improvement followed by relapse. Relieved permanently by glucose.

No. 3. After 62 minutes, convulsions; 6 minims aqueous glucose injected which caused improvement for 16 minutes when relapse occurred. 10 minims aqueous dihydroxyacetone injected. In 15 minutes recovery complete and permanent.

No. 4. After 67 minutes, apparently normal when 6 minims aqueous glyceric aldehyde was injected; 5 minutes later the animal was in convulsions and 10 minims aqueous glucose was given. After a lapse of 10 minutes the animal again normal and remained so.

No. 5. After 75 minutes, in exceedingly violent convulsions. 6 minims aqueous dihydroxyacetone was injected and within 1 minute the animal was better and remained so.

No. 6. Retained as control.

Experiment B with Rabbit.

On April 12th a rabbit weighing 2500 g. was starved for 20 hours and on the following day was given 2 units insulin (B.W. and Co.). As no symptoms developed, the animal was fed in the evening and was again starved the next day. On the 15th, at 11 A.M., 4 units of insulin were given and convulsions began at 1.45 P.M.; these continued intermittently in the usual manner and after 50 minutes the animal, which was still having violent convulsions and was very collapsed, was given 1 g. of glucose subcutaneously. It recovered normally and was fed.

On the 19th the same animal, after having been fasted on the 18th, was given 4 units insulin at 11 A.M.; convulsions began at 12.45 P.M. and became very marked at 1.5 P.M. After violent convulsions it seemed to be moribund and was given 1 g. dihydroxyacetone subcutaneously. Two minutes later it had a very violent bout of convulsions and appeared to be dying with head retracted, limbs outstretched, and respiration very rapid and shallow. But hereafter it began to recover in a manner identical with that seen when glucose was injected; it lay quite relaxed, showed no excessive nervousness, and its breathing improved. In 15 minutes it was sitting up. However, at 3.45 P.M. the animal again collapsed and had slight convulsions. At 3.55 P.M. the blood-sugar was 0·049 per cent.; 1 g. dihydroxyacetone was injected at 3.56 P.M., when the animal promptly recovered. Analyses of the blood-sugar at 4.15 P.M. and at 4.45 P.M. gave respectively 0·086 per cent. and 0·096 per cent. At 4.45 P.M. food was given and the rabbit ate greedily.

Summary.

Before discussing the results obtained in vivo it is necessary to draw attention to the close chemical relationship existing in vitro between the two substances employed. The present authors[2] have succeeded in obtaining proof that glyceric aldehyde when dissolved in water is stable for an indefinite period, but that when rendered only faintly alkaline profound chemical rearrangement takes place with the production of two substances, one a highly reactive, extremely unstable enol which in turn passes to a limited extent into dihydroxyacetone. Conversely this last substance is equally stable in neutral solution but sensitive to alkali, giving rise to the same reactive enol. It is probable that a trace of aldehyde is also formed. The relationship in vitro under conditions of mild alkalinity is, therefore—

Glyceric aldehyde $\rightleftharpoons$ enol $\rightleftharpoons$ dihydroxyacetone.

It will be seen how close a similarity there is to the well-known interconversion of glucose and fructose in dilute alkali. Furthermore, Schmitz[3] has succeeded in preparing from glyceric aldehyde under these conditions α-acrose which is inactive fructose. Hence it is clear that alkali alone will effect the change:

Glyceric aldehyde ⟶ α-acrose ⟶ glucose.

On these theoretical grounds, therefore, one would have postulated that glyceric aldehyde and dihydroxyacetone would have been interchangeable in the body. However, when one examines the relations in vivo it it clear that the aldehyde is incapable of relieving the condition of hypoglycæmia while the ketone is as efficient as is glucose itself.

It is not possible to offer a satisfactory explanation of the results. It seems, nevertheless, not unreasonable to suggest that whatever it be which relieves convulsions after injection of glucose—i.e., whether it be this sugar itself or some derivative, then dihydroxyacetone is capable, in the body, of being converted into this substance and glyceric aldehyde is not, and that in the body the conversion of glyceric aldehyde to dihydroxyacetone does not occur in amount or at a rate which could be detected under the conditions of the experiment. It is, however, an undoubted fact that in the diabetic animal glyceric aldehyde can be converted into glucose, and in the normal animal can be completely oxidised to carbon dioxide and water.[4]

Reconciliation of these facts is not easy if one assumes glyceric aldehyde to be an intermediate product in normal carbohydrate metabolism. The present experiments tend rather to draw attention to the importance of dihydroxyacetone in this connexion.

Conclusions.

(1) In mice and in rabbits rendered hypoglycæmic by insulin, such hypoglycæmia is relieved by dihydroxyacetone and is not relieved by glyceric aldehyde. (2) The hypoglycæmic rodent cannot effect the conversion of glyceric aldehyde to dihydroxyacetone. (3) Dihydroxyacetone is a probable intermediate in the metabolism of carbohydrate.

The authors wish to express their gratitude to Dr. H. W. Dudley for conducting the observations on rabbits. The experiments on mice were carried out by J. A. H.

[1] The technique was essentially that employed by Irvine, Herring, and McLeod (Biochem. Jour., 1924, xviii., 1023).

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—The following new appointments in the Tropical Division have been made; Dr. V. B. Wigglesworth, to be assistant in the department of entomology from Sept. 15th; Miss Joyce Leishman, B.Sc., to be research student and demonstrator in the department of helminthology from Sept. 20th; Dr. Leslie J. Davis, to be research student and demonstrator in the department of tropical pathology and bacteriology from Oct. 1st; and Mr. H. S. Leeson, of the department of entomology, to be assistant to Dr. Ross in Southern Rhodesia for the purposes of carrying out research work in entomology. The post of senior laboratory assistant in the department of entomology, thus rendered vacant, has been filled by the appointment of Mr. H. J. Sutton. Mr. G. H. E. Hopkins, who assisted Dr. Buxton during the Samoan Expedition, has had his appointment extended to the end of the present year. As from Jan. 1st, 1927, Mr. Hopkins has been appointed to undertake research work in the West Indies into the activities of Stegomyia.

Reviews and Notices of Books.

BONE DISEASES.

The Inflammatory and Toxic Diseases of Bone. By R. LAWFORD KNAGGS, *M.C.*, F.R.C.S., Consulting Surgeon to Leeds General Infirmary; formerly Professor of Surgery in the University of Leeds. Bristol: John Wright and Sons, Ltd. 1926. Pp. 416. 20*s*.

GREAT difficulties beset an author who essays to write a treatise upon bone diseases. Exact knowledge of the ultimate meaning of the phenomena of so many of them is wanting; the relationship of signs and symptoms to the pathological process is obscure, so that he is driven to a meticulous description of the minute anatomy, gross appearances, and clinical features without being able to lay emphasis upon the really essential things. Prof. Knaggs has attacked the problem of writing what must necessarily be largely a descriptive treatise so successfully that the reader experiences none of the tedium so often associated with text-books of this kind. In general the author defines the disease and then describes the clinical features of it, thus naturally leading up to accounts of what may be called the museum appearances and histology, followed by a discussion of the pathology. What makes these pages so interesting is the inclusion of accounts of the cases upon which the original descriptions were based. Often, indeed, we read the discoverer's own words. Museums and libraries have been exhaustively searched for illustrative examples, and numerous cases from the author's own extensive experience have been added. How many of us know that the first patient suffering from leontiasis ossea, of whom we have a clinical account, was the son of Fourcade, a Perpignan surgeon? This boy, who began to suffer at 12 years of age, lived to 45, and a most remarkable photograph of his macerated skull appears on page 339. This particular section is a good example of how interesting a complete and scholarly description of an obscure disease can be made. But it is not only the rare conditions which receive such careful treatment. Should the reader desire information upon a common infection such as acute osteomyelitis, he will be sure to find it here, and at the end of the chapter a satisfyingly complete bibliography. There are nearly 200 illustrations, which include a number of exceptionally good microphotographs by Mr. G. R. Rodman.

The author is to be congratulated upon the production of a book which will undoubtedly, owing to its completeness, take its place as a work of reference, whilst at the same time it will be read with enjoyment by all interested in bone diseases.

PUBLIC HEALTH.

A Text-book of Public Health. Ninth edition. By E. W. HOPE, O.B.E., M.D., D.Sc., Professor of Public Health, University of Liverpool; and C. O. STALLYBRASS, M.D., D.P.H., Assistant Medical Officer of Health, City of Liverpool. Edinburgh: E. and S. Livingstone. 1926. Pp. 340. 15*s*.

THIS book has been largely rewritten and brought up to date; new chapters on epidemiology, maternity and child welfare, and industrial hygiene have been added. It now covers adequately, within the scope of 340 pages, the whole field of public health activity. We have examined it closely in order to detect any omission of modern work in the various provinces of hygiene, and are satisfied that no significant extensions of knowledge or changes of opinion have been overlooked by the authors. Even the quite recent work of Patsumi Takahasi and his fellow-workers on the extraction of the fat-soluble vitamin, biosterin, is noticed. Obviously a text-book of this kind suffers a little from its very quality of completeness. It must be compressed into small bulk and is therefore somewhat dogmatic. Moreover, the attempt to fit new theories into old sometimes gives rise to obscurity. For instance, on page 142 it seems to be accepted that sites recently made up by tipping of town refuse are hygienically unsuitable for dwelling-houses, although the influence of such soils on health, if any, is ignored in the section on p. 144, which deals with the relation of soil to disease. An ideal text-book for students on this subject would contain an introductory or concluding chapter dealing with the present state of our knowledge and practice of hygiene, and warning the student that many current views, being the product of empiricism, will probably have to be revised in the light of future scientific experiments. On the whole, however, the authors have successfully steered a middle course between the orthodoxy of the older sanitarians and the tendency to iconoclasm of the younger school. The book is published at a price which brings it within the reach of both the undergraduate and the post-graduate student, to both of whom and to their teachers we commend it without hesitation.

Organisation and Administration of the Public Health Department. By W. A. LEONARD, Chief Clerk and Statistician in the Public Health Department, Birmingham. London: Sir Isaac Pitman and Sons, Ltd. 1926. Pp. 148. 6*s*.

WITH the growth of modern public health departments, and especially of that side of their work which entails the preservation over long periods of records affecting children or persons suffering from chronic ailments, administrative technique has become of increasing moment. It is so important that no medical officer of health can afford to neglect it, and yet it involves so much attention to detail that the medical officer who tries to give this attention may have little time left for cultivating that broader outlook on preventive medicine which is still more essential. It is here that an efficient secretariat counts, and we welcome the publication of a book such as the one under review, which contains the fruit of a layman's long experience in the administration of health matters. Mr. Leonard deals very briefly with the various branches of public health administration, and the bulk of his book is made up of record forms—presumably those used in Birmingham—applicable to each branch. Some of these forms are based on models issued by Government departments, and others are no doubt specially adapted to the circumstances of the town where they were devised, but it is useful to have them bound together for reference. Here and there the letterpress shows a lack of familiarity with generally accepted public health methods, but on the whole it can be recommended to students preparing for a public health or sanitary inspector's qualification, and it will also be of interest to those actually working in public health departments.

"SHOCK" TREATMENT OF MENTAL DISEASES.

Traitement des Maladies Mentales par les Chocs. Par C. PASCAL, Médecin en Chef des Asiles publics d'aliénés de la Seine, et JEAN DAVESNE. Paris: Masson et Cie. 1926. Pp. 184. 2*s*. 6*d*.

A SMALL book which makes suggestive and interesting reading, though there is much in it which the English student will find puzzling, resulting from the habit of some French writers of multiplying divisions and subdivisions of the subject under discussion.

There are two parts to this work. The first deals with the rôle of emotion in the production of the psychoses, and concludes that emotional experiences, whether sudden and acute, or minimal and prolonged, must not be relegated to a secondary place in the causation of mental diseases. The authors insist that affect plays a direct and primary part in the genesis of the psychoses. They recall the work of Cannon, Widal, Abrami, and others, and point out the far-reaching impression of affect on the vegetative nervous system, and so on the whole organism.

Emotions play their part by the biochemical changes they set up. The phenomena of anaphylaxis, sensitisation, desensitisation, hæmoclasic crises, and the proteopexic functions of the liver are all used skilfully by the authors to illustrate the importance of emotional factors in the causation of the psychoses. The second part of the book deals with actual treatment by "shock" methods, such as abscess formation, the injection of peptones and of nucleins, infectious diseases, malarial therapy, tuberculin injections, and the use of radio-active substances. Emotional experiences as curative agents are also discussed, with the mechanism by which such cures might be explained in biochemical terms. The authors may, we believe, lay claim to an original method of "shock" therapy. It consists of the intramuscular injection of blood obtained from a patient who is convalescent after a course of "shock" therapy. The patient giving the blood must obviously be free from syphilis and tuberculosis, and a simple test for determining the compatibility or incompatibility of the two bloods is described. The authors state that satisfactory results are obtained, and that remarkable improvements in the general condition follow a course of these blood injections, which they term "homohémothérapie."

Dr. Pascal and her collaborator have written a work which will be enjoyed by all practising psychiatrists. Some of it may be speculative, but much is original, and suggestive of new outlooks on mental disorders and on their treatment.

PEDIATRICS.

Diseases of the New-born. By J. A. FOOTE, M.D., Professor of Children's Diseases, Georgetown, U.S.A. London: J. B. Lippincott. 1926. Pp. 231. 21*s*.

THIS work, which is described as a monographic handbook, has been written by Prof. Foote in collaboration with five members of the Georgetown Medical Faculty, and gives a comprehensive view of the subject both from the medical and the surgical points of view. It does not confine itself to disease, but contains useful accounts of the routine management of new-born infants and of breast-feeding. Birth palsies and hæmorrhage hardly receive the attention which they deserve, and the only reference to the important work of Schwartz is a footnote on birth hæmorrhage and palsies. Skin affections are described fully, and are particularly well illustrated. A good account is given of the early manifestations of congenital syphilis and their treatment; the author has obtained the best results with the arsphenamin compounds. A most useful chapter contains detailed instructions on the technique of various diagnostic and therapeutic measures, including cistern puncture. This book is clearly written and well illustrated; it should be especially useful to general practitioners who undertake midwifery.

Diagnostik und Therapie der Kinderkrankheiten. Fourth edition. By Prof. F. LUST (Karlsruhe). Berlin and Vienna: Urban and Schwarzenberg. 1926. Pp. 508. M.10.50.

THE fourth edition of Prof. Lust's text-book contains numerous additions throughout the text with but little alteration in form. Close printing and the absence of illustrations render this book much more comprehensive than is indicated by its size, and the ground which is covered is unusually extensive. Scarcely any space is devoted to questions of ætiology or pathology, but concise, condensed accounts are given of the diagnosis and treatment of almost every variation of disease met with in infancy and childhood. A large proportion of the work is devoted to treatment, the author's procedure being to present one method in detail rather than to discuss and compare a number of different ones. The final section contains a large amount of useful information on therapeutics, giving the composition of cereals and other preparations used for infant feeding, and the doses of drugs suitable for different ages. A work of reference for practitioners, this book may be strongly recommended.

Von den Akut-Infektiösen Respirationsstenosen der Kinder. By Dr. DIONYS POPISCHILL (Vienna). Berlin: S. Karger. 1926. Pp. 42. M.2.40.

THIS monograph was to some extent written in response to a series of articles which appeared in the *Deutsche med. Wochenschrift* during the last two years. The author's views differ widely from those of A. Schlossmann, the writer of the first of these articles, who considered that the serum treatment of diphtheria had rendered early tracheotomy unnecessary in all but exceptional cases. Dr. Popischill emphasises the difficulty of differential diagnosis in laryngeal obstruction, or perhaps its impossibility, stating that he has been unable to ascertain whether the infection had been diphtheritic not only in some children who had recovered, but even by post-mortem examination of some fatal cases. He has, moreover, found that the effects of serum in definitely diphtheritic cases has been both too slow and too uncertain to obviate tracheotomy in many patients. He is insistent upon the variability of symptoms and course in different epidemics, and describes the changes which he has observed in the type of disease in Vienna since the 'nineties; this "Genius epidemicus" is to him one of the significant factors in prognosis and treatment. Dr. Popischill considers that low tracheotomy has many advantages over intubation, and that its early application is the safest course in a large number of cases of primary laryngeal diphtheria. He draws attention to the high mortality in cases of secondary tracheotomy after unsuccessful intubation. The relative indications for these two measures in different types of case are fully discussed, as are the uses of morphia, open-air treatment, and baths. This monograph should be of considerable interest to all who are specially concerned with the treatment of infectious fevers.

HANDBOOK ON MEDICAL ELECTRICITY AND RADIOLOGY. By JAMES R. RIDDELL, F.R.F.P.S. Edinburgh: E. and S. Livingstone. 1926. Pp. 239. 8*s*. 6*d*.

THIS handy little volume is written for the student and is intended as a survey of those physical agents which he will find of value in the practice of medicine. The first two chapters are devoted to electrotherapeutics. Diathermy, the most potent of all recent forms in which electrical power has been brought to the aid of the doctor, is adequately dealt with. A chapter is devoted to the rationale and diagnostic use of electrical currents in the examination of nerves and muscles, and includes ten pages of tables and diagrams of motor points. It is a short but very useful section. Passing to X rays, Dr. Riddell summarises the physical aspect of the subject, and succeeds in outlining the salient points of the action of these rays on the living tissues. The diagnostic and therapeutic uses of X rays and radium are compressed into 145 pages, and a few pages on carbon dioxide snow complete the book. When detailing the dangers attendant on the use of radiations, Dr. Riddell states that "the Committee of the National Physical Laboratory has issued recommendations." These recommendations were in fact drawn up by the X Ray and Radium Protection Committee, which is representative of practically all X ray interests. This committee includes a member of the staff of the National Physical Laboratory, which laboratory undertakes to carry out inspection of apparatus and departments, issuing reports as to whether or not these comply with the recommendations.

The author has undertaken an exceedingly difficult if not an impossible task in attempting to give a summary of so many big subjects in so small a compass, and, up to a point, has succeeded fairly well. The book is to some extent marred by the poor quality of the illustrations, which are neither well selected nor

well reproduced. A diagram purporting to represent the normal stomach and duodenum pictures the last-named organ curling inwards towards the spine. But, with its limitations, the book will serve a useful purpose. An outline of this sort represents the minimal equipment which should be possessed by modern practitioners of medicine, and this volume can be recommended to those who have no time to study the subject in more detail.

THE PEAKS OF MEDICAL HISTORY.

An Outline of the Evolution of Medicine. By CHARLES L. DANA, A.M., M.D. New York: Paul B. Hoeber. 1926. Pp. 105. $3.

THIS is a useful little book although of necessity sketchy; an attempt to compress the details of medical history from Hippocrates to Jenner and later into a space of 105 pages leaves a mere outline. Dr. Dana divides the term with which he deals into six periods, the peaks being Hippocrates, the Alexandrian School, Galen, the Renaissance under Vesalius, Harvey and the beginnings of modern physiology, and Jenner and modern medicine. There are a number of excellent illustrations and some useful bibliographical notes, although the statement on p. 97 that Arnold of Villanova was the author of the Regimen Sanitatis Salernitanum requires modification. Another statement on p. 66 should be corrected in a second edition. Dr. Dana, in speaking of Cardan's De Vita Propria, says it "is placed among the three great autobiographies of literature; the other two being Cæsar's 'Annals' and Rousseau's 'Confessions.'" The Annals of Cæsar must come from the same library as that Second Epistle to the Ephesians mentioned by Dickens, and we think that there are other autobiographies which certainly take precedence of those mentioned by Dr. Dana.

JOURNALS.

JOURNAL OF MENTAL SCIENCE.—A special number of this journal is entirely devoted to the presidential address delivered by Lieut.-Colonel J. R. Lord last July at the annual meeting of the Royal Medical Psychological Association. This address contains many valuable and practical suggestions. He is anxious that clinical meetings under the auspices of the Association should be held for much smaller areas than its Divisions now comprise, and that they should not be limited, as heretofore, to members of the Association, but should be open to general practitioners and others in the neighbourhood who might be interested. He further suggests the creation and publication of an authoritative medico-psychological glossary of terms in everyday use in psychiatry and psychology, and appears to have some confidence that the definitions of the glossary would be of general acceptance. Colonel Lord further set before his audience the lofty ideal that every individual case of mental disorder should from its commencement be treated as one for special research; indeed, that there should be no distinction between what is known as "routine practice" and "research." He makes eloquent appeal for the establishment of team-work wherever mental disorder is treated, emphasising the point that the problems of most cases are not to be solved by the unaided effort of any one branch of medicine. It is not to be assumed that in any one case psychogenic ætiological factors are alone at work even if the results of physical examination are negative; nor, similarly, can it be assumed that because physical factors are operating, psychogenic factors are absent. One of the reasons for the issue of this special number is to afford the Association time for the consideration of certain resolutions arising out of the presidential address which will be brought forward at the November quarterly meeting. These resolutions formulate a scheme for the furtherance of research and clinical psychiatry, and a close study of Colonel Lord's address may convince many of the importance of the scheme.

STUDENTS' GUIDE—SESSION 1926–27.

DENTAL SURGERY.

REGISTRATION on the Medical Register entitles a practitioner to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but few dental appointments at general or special hospitals or dispensaries are available save to those with a special diploma.

In THE LANCET of August 28th we outlined the constitution of the Dental Board of the United Kingdom, and the regulations in regard to the registration of dental students.

The Examining Bodies in Dentistry which grant degrees or diplomas in the subject are as follows:—

Royal College of Surgeons of England.—Licence in Dental Surgery.

Royal College of Surgeons, Edinburgh.—Licence in Dental Surgery. The College also grants a Higher Dental Diploma which is registrable in the Dentists Register as an additional qualification.

Royal Faculty of Physicians and Surgeons of Glasgow. Licence in Dental Surgery. The curriculum, which is similar to that of Edinburgh, includes in addition dental bacteriology.

Royal College of Surgeons in Ireland.—Licence in Dental Surgery.

University of Birmingham. — Dental licence; degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.).

University of Bristol.—Licence in Dental Surgery; degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.).

University of Durham.—Licence in Dental Surgery; degrees of Bachelor of Dental Surgery (B.D.S.) and of Master of Dental Surgery (M.D.S.).

University of Leeds.—Licence in Dental Surgery; degrees of Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.).

University of Liverpool.—Licence in Dental Surgery; (L.D.S.); degrees in Dental Surgery (B.D.S. and M.D.S.).

University of London. — Degree of Bachelor in Dental Surgery.

University of Manchester.—Degrees of B.D.S.; and a licence in Dentistry.

University of Sheffield.—Degree of Bachelor of Dental Surgery; and the diploma of Licentiate in Dental Surgery.

Queen's University of Belfast.—Licentiate in Dental Surgery, Bachelor of Dental Surgery, and Master of Dental Surgery.

In the following syllabus the respective requirements of the various examining bodies in dentistry are set forth, together with the facilities for dental study offered by certain other institutions.

THE EXAMINING BODIES IN DENTISTRY.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have passed the required Preliminary Examination in General Education on or after Jan. 1st, 1923.

1. Candidates for the Licence in Dental Surgery of the Royal College of Surgeons of England are required to pass one of the Examinations in General Education recognised by the Conjoint Examining Board in England, and the Pre-Medical Examination in Chemistry and Physics conducted by that Board or one of the examinations recognised in lieu thereof, before they commence the curriculum of professional study for the Licence extending over four years.

2. Candidates who produce evidence of having been registered by the General Medical Council as Medical or Dental Students on or after Jan. 1st, 1923, will be considered to have passed the required Preliminary Examination in General Education and the Pre-Medical Examination.

3. Candidates who hold the degree of D.M.D. Harvard, D.D.S. Pennsylvania, D.D.S. Michigan, D.D.S. Illinois, D.D.S. St. Louis, Missouri, D.D.S. Northwestern University, Chicago, D.D.S. Minnesota, D.D.S. Tufts College, Boston, B.D.S. Sydney, or the Licence of the Dental Board of Victoria, Australia, are not required to pass these Examinations.

First Professional Examination.—1. The First Professional Examination consists of Part I. Dental Mechanics, Part II. Dental Metallurgy and the Properties of Dental Materials, and Part III. Section (*a*) General Anatomy and Physiology, Section (*b*) Dental Anatomy and Physiology, and is held in January or February, April, and September or October in each year.

2. Candidates may present themselves for the several Parts of the First Professional Examination together or separately, but before admission to any part of the Examination they must produce evidence of having passed the required Preliminary Examination in General Education and the required Pre-Medical Examination or a certificate of having been registered as a Medical or Dental Student by the General Medical Council.

Part I. *Dental Mechanics.*—3. This Examination is a practical one, conducted in the Mechanical Laboratory of one of the Dental Hospitals in London.

4. Candidates must give 21 days' notice in writing of their intention to present themselves for the Examination, and at the same time forward certificates :—

(1) Of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Dental Mechanics. One year at least of this study must be taken in the Mechanical Department of a recognised Dental Hospital where the arrangements for teaching Dental Mechanics are satisfactory to the Board of Examiners in Dental Surgery. Part or the whole of the rest of the course may be taken as a pupil with a competent dentist provided that time spent as a private pupil shall be at least twice the time required for the corresponding instruction* taken at a Dental School.

(2) Of having attended at a recognised Dental Hospital and School: (*a*) A course of lectures on Dental Mechanics; (*b*) a course of Practical Dental Mechanics, including the manufacture and adjustment of 6 dentures and 6 crowns.

6. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required, before admission to re-examination, to produce a certificate of having received three months further instruction under the conditions specified in Certificate (1) paragraph 4.

Part II. *Dental Metallurgy and the Properties of Dental Materials.*—7. This Examination is conducted by written paper.

8. Candidates must give 21 days' notice in writing of their intention to present themselves for the Examination, and at the same time forward a certificate :—Of having attended at a recognised Dental Hospital and School: (*a*) A course of lectures on Dental Metallurgy; (*b*) a course of Practical Dental Metallurgy.

9. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required, before admission to re-examination, to produce a certificate of having worked in a Dental School, to the satisfaction of the Dean, for a further period of three months.

Part III. (*a*) *General Anatomy and Physiology*, (*b*) *Dental Anatomy and Physiology.*—10. This Examination is partly written and partly oral.

11. Candidates may enter for Section (*a*) only or for Sections (*a*) and (*b*) together on producing the required certificates, but they will not be allowed to proceed with Section (*b*) until they have passed in Section (*a*). In the case of a candidate who enters for both Sections and fails in Section (*a*) the fee paid for admission to Section (*b*) will not be forfeited, but will be credited to the candidate on readmission to examination in that Section. Candidates who enter for both Sections together may pass in Section (*a*) although failing to pass in Section (*b*).

12. Candidates must give 21 days' notice in writing of their intention to present themselves for the whole or for one Section of this examination and at the same time forward certificates :—

(1) For Part III. (*a*). Of having attended at a recognised Medical School: (*a*) Courses of instruction in Anatomy, including special demonstrations on prepared dissections during three terms; (*b*) a course of dissections to include, if possible, the head and neck, during one term; (*c*) courses of instruction in Physiology, including General Biology, Biochemistry, and Biophysics, during three terms; (*d*) a course of instruction in Histology.

(2) For Part III. (*b*). Of having attended at a recognised Dental School: (*a*) A course of instruction in Dental Anatomy and Physiology; (*b*) a separate course of instruction in Dental Histology, including the preparation of Microscopical Sections.

13. A candidate referred at this examination who does not hold a registrable Dental Qualification will be required, before readmission to Section (*a*), to produce a certificate of three months' additional study of Anatomy and Physiology at a recognised Medical School, and will be required before readmission to Section (*b*) to produce a certificate of having worked in a Dental School, to the satisfaction of the Dean, for a further period of three months.

14. *Exemptions.*—Candidates who have passed Section I. of the First Professional Examination of the Conjoint Examining Board in England, or who produce evidence of having passed the Examination in Anatomy and Physiology for a degree, or other qualification, in Medicine or Surgery, registrable under the Medical Act of 1886, or for the degree of M.B. or M.D. of a Foreign or Colonial University recognised by the Conjoint Examining Board in England, are not required to pass Section (*a*).

Second Professional Examination.—1. The Second Professional Examination is held in February, May or June, and November in each year, and consists of: Part I., General Surgery and Pathology; Part II., Dental Surgery and Pathology, and Practical Dental Surgery.

2. Candidates who have passed the First Professional Examination at least four months† previously may present themselves for Part I. only on producing the certificates mentioned in paragraph 6 of this section, or they may enter for the whole Examination at one time on producing the certificates mentioned in paragraphs 6 and 10 of this section.

3. Candidates must pass in Part I. before proceeding to Part II.

4. Candidates who enter for the whole Examination at one time may pass in Part I. although failing to pass in Part II.; but if they fail to pass in Part I. they will not be allowed to proceed with the Practical and Oral Examinations in Part II. In such cases the fee paid for admission to Part II. will not be forfeited, but will be held over until such time as the candidate is readmitted to examination in that Part.

Part I. *General Surgery and Pathology.*—5. This Examination is partly written and partly oral.

6. Candidates must give 21 days' notice in writing of their intention to present themselves for this Examination, and at the same time forward certificates :—

(1) Of having attended at a recognised Medical School: (*a*) A course of instruction‡ in Surgery during two terms; (*b*) a course of instruction in Medicine during two terms; (*c*) a course of instruction in General Pathology (including Bacteriology) during two terms. (2) Of having acted as Surgical Dresser in the Out-patient Department of a recognised Hospital for three months. (3) Of having attended, at a recognised Hospital or Hospitals, the practice of Medicine

* This instruction may be taken prior to the date of passing the Examination in General Education and the Pre-Medical Examination, but will not be counted as part of the required four years of professional study unless taken after passing the Pre-Medical Examination.

† The interval of six months is not required in the case of a colonial or foreign dentist.

‡ These courses of instruction must be attended after the completion of the courses in Anatomy and Physiology.

and Surgery, including clinical lectures, for 12 months. (4) Of being 21 years of age.

7. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required, before admission to re-examination, to produce a certificate of such additional study during three months at a recognised Medical School and Hospital as the Teachers of the School may determine.

Exemptions.—8. Candidates who are Members of the College or who have passed the Examination in Surgery of the Conjoint Examining Board in England, or who produce evidence of having passed the Examination in Surgery for a Degree, or other Qualification in Medicine or Surgery registrable under the Medical Act of 1886, are not required to pass Part I. of the Second Professional Examination.

Part II. *Dental Surgery and Pathology.*—9. This Examination is partly written, partly oral, and partly practical. The oral examination is conducted by the use of preparations, casts, drawings, &c. At the practical examination candidates may be examined :—

(*a*) On the treatment of Dental Caries, on the preparation and treatment of teeth by filling with gold or other material, by inlaying or by crowning, and on other operations in Dental Surgery. (Candidates must provide their own instruments.) (*b*) On the treatment of abnormalities of position of the teeth of children. (*c*) On Clinical cases.

10. Candidates must give 21 days' notice in writing of their intention to present themselves for this Examination, and at the same time forward certificates :—

(1) Of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a Medical or Dental Student, or of having passed the Pre-Medical Examination conducted or recognised by the Conjoint Examining Board in England. (2) Of having attended at a recognised Dental Hospital and School : (*a*) A course of Dental Surgery and Pathology ; (*b*) a separate course of Practical Dental Surgery ; (*c*) a course of Dental Bacteriology ; (*d*) a course of Dental Materia Medica ; (*e*) a course of practical instruction in the administration of such Anæsthetics as are in common use in Dental Surgery. (3) Of having attended at a recognised Dental Hospital and School, or in the Dental Department of a recognised General Hospital, the practice of Dental Surgery during two years.

11. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required before admission to re-examination to produce a certificate of three months' additional study at a recognised Dental Hospital.

Fees.—The fee for the Diploma in Dental Surgery is 20 guineas.

Synopses of examinations and all further information can be obtained from the Director of Examinations, Examination Hall, Queen-square, London, W.C. 1.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—Regulations giving a list of Preliminary Examinations recognised for obtaining the Licence in Dental Surgery, as well as of the subjects of the Professional Examinations, may be obtained from Mr. D. L. Eadie, Clerk to the Royal College of Surgeons, at 49, Lauriston-place, Edinburgh. Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates must also have attended a course of instruction at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the Diploma in Surgery. In addition they will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, special courses of lectures and instruction in Anatomy and Physiology (Human and Comparative), Surgery, Pathology, Materia Medica, Dental Histology, and Practical Dental Mechanics and Metallurgy ; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Practical instruction in Mechanical Dentistry from a registered Dentist, or in the Mechanical Department of a recognised Dental Hospital and School, for three years. Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination, and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations, and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma. First Professional Examination : The candidate must have attended the required courses. The examination embraces (1) Chemistry and Physics ; and (2) Anatomy and Physiology. The fee is £5 5*s.* for the complete examination, and £3 3*s.* is payable for each division. In all cases of rejected candidates the fee for re-entry is £3 3*s.* Second Examination : The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is 21 years of age, and must pay a fee of £10 10*s.*, for re-entry £5 5*s.* The examination embraces (1) Surgery and Medicine ; and (2) the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, Dental Materia Medica, Dental Mechanics and Dental Metallurgy, with a practical as well as the written and oral examinations in the subjects of Dental and Oral Surgery, Pathology, and Mechanics. The candidate will be tested in the Treatment of Dental Diseases, in Operative Dentistry, the Administration of Anæsthetics, Orthodontics, and in Prosthetic and Mechanical Dentistry. Candidates who claim exemption from the First Dental Examination on the ground of having passed the First and Second Triple Qualification Examinations or other recognised examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £15 15*s.* payable for the dental diploma. Candidates applying for copies of Regulations should state date of registration as a dental student. Fees and schedules must be lodged with the Clerk not later than one week before the examination.

Separate Regulations are issued for candidates registered as Dental Students after Jan. 1st, 1923, for whom there is a much more extended course.

Higher Dental Diploma.—The College grants a Higher Dental Diploma which is registrable in the Dentists Register as an additional qualification. Every candidate for the Higher Dental Diploma shall produce evidence that he has been engaged in the study or practice of his profession as a Registered Dentist for at least one year subsequent to his having obtained the Licence in Dental Surgery of the College, or a Licence or Qualification in Dental Surgery specially recognised by the College. Particulars as to the examinations can be obtained from Mr. D. L. Eadie, Clerk to the Royal College of Surgeons, 49, Lauriston-place, Edinburgh. The fee payable by Licentiates of the College is £15 15*s.* For all other candidates £21. A fee of £10 10*s.* is retained for examination expenses in the case of referred candidates.

The examination embraces the following branches of Dental Science and practice : Dental Surgery, Anatomy, Pathology and Bacteriology, Prosthesis, Anæsthesia, and Dental Radiology. The examination will be clinical and practical as well as written and oral. Candidates will be expected to show a high degree of knowledge and skill.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh, but embrace Dental Bac-

teriology. Candidates can enter for the First Examination in three divisions, the first embracing Physics and Chemistry, the second Dental Metallurgy and Dental Mechanics, and the third Anatomy and Physiology. The examination in Dental Mechanics is practical; and there is at the Final Examination an examination in Practical Dentistry conducted in a dental hospital. Copies of regulations, &c., to be obtained from Mr. Walter Hurst, Registrar, Faculty Hall, 242, St. Vincent-street, Glasgow. Candidates applying for Regulations should state date of registration as a dental student.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Candidates for the licence in Dental Surgery are required to pass three professional examinations, and to produce certificates of having, subsequently to registration as a Dental Student, passed the examination in Biology, and attended courses of instruction in the following subjects at a recognised school of medicine: (*a*) Human anatomy, with dissections and demonstrations, for three academic terms. (*b*) Physiology, theoretical and practical, including Dental Physiology lectures for two academic terms. (*c*) Histology, for one academic term. (*d*) Chemistry and Physics as applied to Dentistry. For the second examination certificates must be produced of having attended, at an institution recognised by the College for the purpose, the following courses: (*a*) General Pathology (including Bacteriology) for three academic terms. (*b*) Medicine for two academic terms. (*c*) Surgery for two academic terms. (*d*) The practice of a general hospital, with certified instruction in Clinical Medicine, Clinical Surgery, and Venereal Diseases, for three academic terms. For the final examination evidence must be produced of having been engaged during a period of two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the direction of the Superintendent of the Mechanical Department of a recognised Dental Hospital where the arrangements for teaching Mechanical Dentistry are satisfactory to the Council of the College; of having attended, at a recognised institution, courses of instruction in (*a*) Dental Surgery and Pathology, Orthodontia, and the Materia Medica and Therapeutics applicable to Dental Surgery. Lectures. Two courses. (*b*) Dental Mechanics. Lectures. Two courses. (*c*) Anæsthetics. One course. (*d*) The practice of a Dental Hospital, or of the Dental Department of a General Hospital. Twenty-four calendar months. (*e*) Dental Metallurgy. (*f*) A course of Radiology; of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a Dental Student; four years of professional study; and of being 21 years of age.

The subjects of the first examination are Anatomy, General, and Physiology and Histology. For the second examination (*a*) General Pathology (including Bacteriology), (*b*) Medicine and Surgery. For the Final Examination, General Surgery and Dental Pathology, with the Materia Medica and Therapeutics applicable to Dental Surgery, Dental Mechanics and Metallurgy, Anæsthetics, Orthodontia. Candidates must pass in all the subjects set at each examination which in the second and final parts will be partly vivâ voce and partly practical, and will include the examination of patients and the performance of dental operations. The total fee for the Diploma in Dental Surgery is 21 guineas.

UNIVERSITY OF BIRMINGHAM.—The teaching of Dentistry is undertaken by the University acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board. The instruction at the Dental Hospital is carried out under the direction of the University Dental Clinical Board, so that students may fully qualify themselves for the Dental Diploma (L.D.S.) of this and other universities and licensing bodies. There is a special and well-equipped Dental Museum: The "John Humphreys Odontological Museum." An Entrance Exhibition, value £37 10*s.*, is awarded annually at the commencement of the winter session. The following are the regulations for Degrees in Dentistry:—

1. The degrees conferred by the University are those of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.). 2. All candidates for these degrees must pass the same Matriculation Examination as that required from candidates for Medical Degrees. 3. The degree of Bachelor of Dental Surgery is not conferred upon any candidate who has not obtained a Licence in Dental Surgery. The candidate is not eligible for the degree until a period of 12 months has elapsed from the passing of his examination for the Licence in Dental Surgery. Of this period at least six months must be spent in the dental department of a general hospital approved by the University. 4. *A.* In addition to the Licence in Dental Surgery the candidate must produce evidence that he has attended the courses required by medical students of the University in the following subjects and passed the Examinations held in the same for Medical and Surgical Degrees: (*a*) Elementary Biology and Organic Chemistry, (*b*) Anatomy and Practical Anatomy, and (*c*) Physiology and Practical Physiology. *B.* That he has passed the class examinations in: (*d*) One Special Course of Lectures on Medicine, (*e*) One Special Course of Lectures on Surgery, and (*f*) Pathology and Bacteriology. *C.* That he has attended courses and passed the class examinations in: (*g*) Dental Histology and Patho-Histology, (*h*) Comparative Dental Anatomy, and (*k*) Dental Surgery and Prosthetic Dentistry. *D.* That he has received instruction in the Clinical Examination of living cases at the dental department of a general hospital for a period of not less than six months. 5. The Final Examination will deal with the subjects in Classes *C* and *D*. 6. On the expiration of 12 months from the date of passing the Examination for the Degree of Bachelor of Dental Surgery, the candidate will be eligible for that of Master of Dental Surgery. 7. For this degree candidates will be required to submit a thesis containing original work, and investigations in some subject connected with Dentistry, which theses shall be submitted to examiners to be nominated by the Dental Advisory Board.

UNIVERSITY OF BRISTOL.—Candidates for the degree of Bachelor of Dental Surgery must be not less than 21 years of age and shall have pursued the courses prescribed by University regulations during not less than four years after passing the first examination in the subjects of Chemistry and Physics, of which three shall have been passed in the University. All candidates for the degree of B.D.S. are required to satisfy the examiners in the several subjects of four examinations. The First Examination: The subjects are Chemistry, Physics, and Biology, and the curriculum extends over one year.* The Third Examination: The subjects are Dental Mechanics, Dental Metallurgy, and Dental Materia Medica, and the candidate shall produce evidence of having served for three years an approved pupilage in Dental Mechanics.† The Second Examination: The subjects are Anatomy, Physiology, and Histology, Dental Anatomy, and Dental Histology. The Final Examination: The subjects are Medicine and Surgery, Dental Surgery (including Prosthetics), Operative Dental Surgery, and Dental Bacteriology. Degree of Master of Dental Surgery: Candidates shall be Bachelors of the University, shall present a Dissertation on some subject of Dental Surgery to be approved by the Examiners, and pass an examination in Dental Surgery. Diploma in Dental Surgery: Candidates need not be undergraduates, but shall have passed an entrance examination satisfactory to the University before being admitted

* Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination for either the B.D.S. or the L.D.S., and will be regarded as having completed one year of study.

† This pupilage must be taken either in the University laboratories or those of some institution recognised for the purpose by the University.

to any professional examination; the curriculum extends over four years from the date of passing a preliminary science examination in Chemistry and Physics. A three years' pupilage in Mechanical Dentistry is required† and four examinations must be passed, the subjects of which agree with those of the B.D.S. Medicine is not required for the Final Examination. Candidates who are already registered medical practitioners shall be further exempted from study and examination in Physics and Chemistry, Anatomy, Physiology and Histology, Medicine, and General Surgery.

UNIVERSITY OF DURHAM.—Every Dental student must, at the commencement of his studentship, be registered in the manner and under the conditions prescribed for Medical students.

Licence in Dental Surgery: The first examination consists of three parts, which may be passed separately. Part 1, Organic Chemistry. Part 2, Biology. Part 3, Theoretical Dental Mechanics, Dental Metallurgy (Theoretical and Practical). Second Examination: Anatomy, Physiology (including Biochemistry and Biophysics), Dental Anatomy and Dental Histology. Third Examination: Pathology and Bacteriology, Practical Dental Mechanics, Dental Materia Medica and Therapeutics. Final Examination: Medicine, Surgery, Dental Surgery and Pathology, Orthodontics, Operative Dental Surgery, and Dental Prosthetics, and Anæsthetics.

A candidate before presenting himself for examination is required to furnish certificates of instruction in the required subjects, attended after registration as a dental student at recognised Colleges or Schools.

Degree of Bachelor of Dental Surgery (B.D.S.).—(*a*) For students taking their complete course of instruction in the University. Such students must pass the same matriculation tests as medical students, and the same pre-registration examination in Inorganic Chemistry and Physics. After registration students must spend five years in the University, on attendance on such subjects as Senate, on the recommendation of the Board of the Faculty of Medicine, may from time to time determine. They must attend the practice of the Newcastle-upon-Tyne Dental Hospital for not less than two and a half years. Six months of this time must be devoted to the study of the higher branches of dental science. There are four examinations.

The subjects of the *first* examination are Biology, Organic Chemistry, and Dental Mechanics and Metallurgy.

The subjects of the *second* examination are Anatomy, Physiology, Dental Anatomy and Histology.

The subjects of the *third* examination are Pathology and Bacteriology, Dental Materia Medica and Therapeutics, and Practical Dental Mechanics.

The subjects of the *final* examination are Medicine, Surgery, Dental Surgery and Pathology, and Orthodontia and Operative Dental Surgery. In this subject knowledge of a much higher standard, and more advanced practical work, is required than for the Licence in Dental Surgery.

(*b*) For candidates possessing a Licence in Dental Surgery of a British University. Candidates must study for at least one year in the University. During such year they must (*a*) attend a course of instruction in Pathology and Bacteriology, and (*b*) spend at least six months in the Newcastle-upon-Tyne Dental Hospital in the study and practice of the higher branches of dental science. They must also pass the third and final examinations for the degree of Bachelor of Dental Surgery.

Degree of Master of Dental Surgery (M.D.S.).—Every candidate for this degree must be a Bachelor of Dental Surgery of the University of not less than two years' standing, and present an essay embodying original work and research in some subject connected with dentistry. They must also perform to the satisfaction of the examiners a piece of special dental work demanding a high degree of skill and experience.

The examinations are held concurrently with the medical examinations, and the fees payable by candidates are as follow:—For the Licence in Dental Surgery: First, Second, and Third Examinations, each £3 10*s.*; Final Examination, £5; for Licence, £3; total, £18 10*s.* For the Bachelor of Dental Surgery: First, Second, and Third Examinations, each £5; Final Examination, £8; for the degree, £6 16*s.*; total, £29 16*s.* For the Master in Dental Surgery: examination, £5; degree fee, £6 6*s.* The practical examinations in dentistry are conducted at the Newcastle Dental Hospital.

UNIVERSITY OF LEEDS.—The degrees in Dental Surgery are Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.). All candidates for the degree of Bachelor of Dental Surgery shall be required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the date of passing Parts I. and II. of the First Examination, and to have completed such period of pupilage or hospital attendance, or both, as may be prescribed by the regulations of the University. No candidate will be admitted to the degree who has not attained the age of 21 years on the day of graduation. The Diploma in Dental Surgery (L.D.S.) is awarded to successful candidates after attendance on approved courses extending over not less than four years. The curriculum for the Diploma now includes the study of Biology for the First Examination. The classes in the Department of Dentistry begin on Oct. 1st. The instruction in the Preliminary subjects of Chemistry, Physics, and Biology are given in the main buildings of the University. The classes in the other subjects and the systematic courses in Dental subjects are held in the School of Medicine of the University in Thoresby-place. The clinical instruction is given in the Dental Hospital at the Leeds General Infirmary. Applications for the prospectus should be made to the Academic Sub-Dean of the Faculty of Medicine.

UNIVERSITY OF LIVERPOOL.—The University grants a Licence in Dental Surgery (L.D.S.) and degrees in Dental Surgery (B.D.S. and M.D.S.). The management of the curriculum (lectures, practical and clinical) is in the hands of the University Board of Dental Studies. The courses of systematic instruction are given in the main University buildings, and those in Dental Mechanics, Operative Dental Surgery, &c., are given in the University School Extension (opened 1922), adjoining the Dental Hospital, the laboratory of which is in charge of a skilled dental mechanic under the supervision of the Director of Dental Education. The clinical instruction is given in the Dental Hospital. Students can take the whole curriculum, including Dental Mechanics, at the University School of Dental Surgery. The times of the lectures at the University are arranged to meet the convenience of students, thus allowing the maximum time for attendance upon Dental Hospital practice. Fees: The fees for the complete courses, including Pupilage and Hospital Practice, are as follows: Degree of B.D.S., £250; M.D.S. (by research, £32; by examination, £27); L.D.S. (Liverpool), £198. Further information may be had from the Director of Dental Education, Prof. W. H. Gilmour.

In order to be admitted to the Bachelor's Degree in Dental Surgery a student must normally, after registration as an Internal Student, have—(1) Attended prescribed courses of study for five years at one or more Schools of the University. (2) Passed the following examinations:—(*a*) First Examination: *Part A:* (i.) Chemistry, (ii.) Physics, (iii.) Biology (Zoology and Botany); *Part B:* (iv.) Dental Metallurgy. Candidates may take Parts A and B separately. (*b*) Second Examination: *Part A* (i.) Anatomy, (ii.) Dental Anatomy, Dental Physiology, and Dental Histology; *Part B:* (iii.) Physiology; *Part C:* (iv.) Dental Mechanics,

Candidates may take Part A separately but must take Parts B and C together. Third Examination: *Part A:* (i.) Elementary Bacteriology, (ii.) Clinical Chemistry, (iii.) General Pathology; *Part B:* (iv.) Dental Materia Medica, (v.) Dental Mechanics and Dental Prosthetics. Candidates may take Parts A and B separately. Students who have received not less than two years' instruction in Dental Mechanics previous to Nov. 30th, 1922, with a Dentist registered under the provisions of the Dentists Act (1921) and who have passed a recognised examination in preliminary education may, on application, be registered as students for the Licence under certain conditions.

UNIVERSITY OF LONDON.—The curriculum for the degree of Bachelor of Dental Surgery covers five years from Matriculation. The Regulations for Internal and External Students may be obtained post-free on application to the Academic Registrar, at the University.

UNIVERSITY OF MANCHESTER.—In the University of Manchester the Dental Department forms an integral part of the Faculty of Medicine. This contains a series of laboratories, lecture rooms, and museums which will bear comparison with those of any other school in the kingdom, and the fullest opportunities for study are offered to students preparing for any of the professional examinations. Instruction adapted to the requirements of students preparing for the B.D.S. Degree and the Dental Diplomas of the University, the Royal College of Surgeons of England, and of other licensing bodies is given throughout the session both at the University and at the Dental Hospital of Manchester adjoining the University. The required general hospital practice is taken at the Manchester Royal Infirmary. Women students are admitted to the classes in the Dental Department, and for them common rooms are provided. The composition fee for candidates for the University degree of Bachelor of Dental Surgery is 94½ guineas, payable in three equal yearly instalments. The composition fee for candidates for the University Diploma in Dentistry is 84½ guineas, payable in three equal yearly instalments. The composition fee for candidates for the L.D.S. of England is 94½ guineas, payable in three equal yearly instalments. Students who have already served their apprenticeship with a private practitioner, and who propose to complete the final portion of their attendance at the University and at an approved dental hospital, will be required to pay the composition fee in two equal instalments at the commencement of the first and second years of studentship. The composition fee does not include the hospital fees, the examination fees, nor the fee for the conferment of the degree or the diploma.

UNIVERSITY OF SHEFFIELD.—*Degree of Bachelor of Dental Surgery.*—A candidate must have attained the age of 22 years on the day of graduation and have pursued the courses of study required by the University regulations during a period of not less than five and a half years subsequent to matriculation and the passing of the further examination in Chemistry and Physics, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination.

First Examination: The subject of the examination is Biology. Candidates must have attended a course of instruction for one year after matriculation and the passing of the further examination in Chemistry and Physics. Second Examination: The subjects of the examination are Anatomy, Physiology, Dental Anatomy, Physiology and Histology; Dental Mechanics, Dental Metallurgy. Final Examination: The subjects of the examination are: Part I., Pathology and Bacteriology; Part II., Medicine and Surgery, Dental Surgery, including Materia Medica and Therapeutics. Candidates for Part II. must have completed five and a half years of professional study.

Degree of Master of Dental Surgery.—Candidates must have passed the examination for the degree of B.D.S. at least one year previously and before admission to the examination must have held for not less than six months a dental appointment in a hospital affording full opportunity for the study of Dental Surgery. Candidates shall not be required to but may present a thesis embodying observations in some subject approved by the Faculty and a candidate whose thesis is of exceptional merit may be exempted from any part of the examination.

Diploma of Licentiate in Dental Surgery.—A candidate must have attained the age of 21 years on the day upon which he is to receive the diploma, and have pursued the courses of study required by the University regulations during a period of not less than four years subsequently to passing the preliminary examination and the passing of the further examination in Chemistry and Physics. Two years must be passed in the University, one at least being subsequent to the passing of the First Examination.

First Examination: The subject of the examination is Biology. Candidates must have attended a course of instruction for one year. Second Examination: The subjects of the examination are Anatomy and Physiology, Dental Anatomy and Physiology, Dental Mechanics, Dental Metallurgy. Final Examination: The subjects of the examination are: Part I., Pathology and Bacteriology; Part II., Medicine and Surgery, Dental Surgery, including Materia Medica and Therapeutics. Candidates for Part II. must have completed the fourth year of professional study.

The Dental Composition Fees are as follows:—

For B.D.S.: 1st and 3rd years, £75; 2nd, 4th, and 5th years, £25.

For L.D.S.: 1st and 2nd years, £75; 3rd and 4th years, £25.

QUEEN'S UNIVERSITY OF BELFAST.—The following degrees and diplomas are now conferred: Licentiate in Dental Surgery, Bachelor of Dental Surgery, and Master of Dental Surgery. Lecturers have been appointed in Dental Surgery, Dental Mechanics, Dental Metallurgy and Materia Medica, and Orthodontia.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 18TH, 1926.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 120 (last week 106); scarlet fever, 1392; diphtheria, 973; enteric fever, 71; pneumonia, 409; puerperal fever, 45; cerebro-spinal fever, 4; acute poliomyelitis, 75; acute polio-encephalitis, 2; encephalitis lethargica, 38; continued fever, 3; dysentery, 28; ophthalmia neonatorum, 95. There were no cases of cholera, plague, or typhus fever notified during the week.

The notifications of poliomyelitis, which are 22 more than last week, come from many parts of the country, with special incidence in the county of Essex, 7; Hertford, 4; Kent, 5; Leicester, 31 (16 of these from Leicester C.B.); and Warwick, 4.

Of the 120 cases of small-pox, 96 were reported from the counties of Northumberland (10) and Durham (86). In Gateshead 19 cases (some of them since the issue of this return) are said to owe their origin to a family in which the children, although ill, were not medically examined and returned to school in an infectious condition.

Deaths.—In the aggregate of great towns including London, there were no deaths from small-pox, 5 (2) from enteric fever, 1 (0) from measles, 2 (1) from scarlet fever, 26 (1) from whooping-cough, 24 (2) from diphtheria, 217 (39) from diarrhœa and enteritis under 2 years, and 19 (4) from influenza. The figures in parentheses are those for London itself. A week with only a single death from measles is noteworthy.

Messrs. Allen and Unwin announce the forthcoming publication of "Fundamentals of School Health," by Dr. James Kerr.

THE LANCET.

LONDON: SATURDAY, OCTOBER 2, 1926.

BILIARY PHYSIOLOGY AND PATHOLOGY.

THE departments of medicine are no exception to DANTE GABRIEL ROSSETTI'S dictum

> ". . . . Till the world shall burn,
> It seems that all things take their turn;"

the nervous, respiratory, cardiovascular, and other systems have had their day of special popularity, and their intensive investigation, of course, continues. More recently the alimentary canal and its appendages, which for a time were being peacefully or otherwise penetrated by the surgeon, have been the subject of more extensive biochemical and experimental research, such as the fractional test-meals initiated by REHFUSS, of Philadelphia, and introduced into this country by Dr. ARTHUR HURST; the tests for hepatic efficiency (L. G. ROWNTREE, S. M. ROSENTHAL, G. H. WHIPPLE, H. MACLEAN and DE WESSELOW, HIJAMS VAN DEN BERGH), and the brilliant researches on biliary secretion of PEYTON ROUS and his collaborators at the Rockefeller Institute, New York; and of R. H. T. MANN and his team at the Mayo Clinic, Rochester. A sign of the times is found in the repeated discussions at the Medical Section of the British Medical Association on hepatic and biliary disease in alternate years since 1922; Prof. D. P. D. WILKIE, who took part in the recent discussion at Nottingham on Some Recent Developments in our Knowledge of the Biliary Tract (THE LANCET, July 31st, p. 234), opened by a fellow professor of surgery, EVARTS A. GRAHAM, of Washington University, St. Louis, U.S.A., now publishes (p. 689) an address delivered at St. Mary's Hospital Medical School on May 27th last on the Functions of the Biliary Passages in Relation to their Pathology. In this lecture he reviews the recent additions to our knowledge and from a wide practical experience provides thoughtful suggestions as to their bearing on the clinical manifestations of biliary disease.

The detection of the early stages of disease—that is, of a departure from normal function—necessitates an accurate knowledge of the healthy organism, and with regard to the physiology of the biliary tract there is not yet complete agreement on some points; for instance, there is considerable difference of opinion on the question whether or not the gall-bladder contracts; Prof. WILKIE speaks of its rhythmic contractions as a factor in assisting the concentration of the contained bile, and MCMASTER and ELMAN, of the Rockefeller Institute, in recent papers have proved experimentally that the gall-bladder of the unanæsthetised dog responds to the stimulation exerted by food with fairly vigorous contractions. If the gall-bladder does not possess the power of muscular contraction, as EVARTS GRAHAM and others have argued on the basis of direct observation of gall-bladders in many operations on man and in experiments under anæsthesia, while the bile-ducts are practically devoid of smooth muscle, the question arises as to the mechanism by which biliary colic—perhaps the most severe pain that human flesh is heir to—is produced. In addition to a sphincter-like collection of muscular fibres at the neck of the gall-bladder, as shown in Fig. III. (see plate) there is the well-known Oddi's sphincter at the lower end of the common bile-duct, which is tonically contracted except when bile is passing into the duodenum; from the available evidence Prof. WILKIE makes some suggestions as to the importance and results of persistent spasm of Oddi's sphincter, and mentions pain, though not frank biliary colic in so many words, as a result of spasm of this sphincter. Another result is biliary stasis, spoken of, therefore, as hypertonic stasis; and the influence of hypersensitiveness of the sphincter associated with the hypercholesterolæmia of pregnancy and arteriosclerosis in causing biliary stasis and so disposing to infection, cholecystitis, and gall-stones, is a very interesting possibility; it is suggested that the excess of cholesterol in the blood is the disposing factor to the hypervagotonia and so to persistent spasm of Oddi's sphincter. As spasm of the sphincter may cause biliary stasis and dilatation of the gall-bladder, it seems reasonable to believe that it may be responsible for the rare condition of cystic dilatation of the extrahepatic bile-ducts, and Prof. WILKIE compares the underlying want of neuromuscular coördination which leads to failure in relaxation of Oddi's sphincter, or achalazia, with that responsible for cardiaspasm, idiopathic dilatation of the colon, congenital pyloric stenosis, and some forms of hydronephrosis. He also suggests that persistent spasm of Oddi's sphincter is the cause of the pains and transient jaundice occasionally seen after cholecystectomy, which naturally suggest an overlooked stone in the common duct, but in which a second operation reveals nothing save a dilated common bile-duct. This possibility of achalazia of the lower end of the common bile-duct after removal of the gall-bladder recalls Meltzer's law of contrary innervation of the gall-bladder and Oddi's sphincter—namely, that Oddi's sphincter remains in tonic contraction until the gall-bladder contracts, when it relaxes. It might, indeed, be logically imagined that after removal of the gall-bladder Oddi's sphincter would fail to relax; the reverse, however, usually occurs, for at first at any rate, and sometimes perpetually, there is biliary incompetence and the bile flows continuously into the duodenum. It would be interesting to know what factors govern the behaviour of Oddi's sphincter after cholecystectomy. The occasional onset of acute hæmorrhagic pancreatitis in biliary disease is well established; in 1901 HALSTED and OPIE put forward the attractive explanation that this accident was due to retrojection of bile into Wirsung's duct of the pancreas as a result of impaction of a small calculus in the biliary papilla; the presence of a gall-stone in the biliary papilla is by no means constant in acute hæmorrhagic pancreatitis, and ARCHIBALD'S suggestion, modified by MANN and GIORDANO, of spasm of the terminal or papillary portion of Oddi's sphincter, which would throw the biliary and pancreatic ducts into one, is quoted by Prof. WILKIE.

In addition to biliary stasis due to spasm of Oddi's sphincter there is the hypotonic gall-bladder met with in asthenic visceroptosis and, indeed, part of that condition; the symptoms suggest gall-bladder disease, but laparotomy shows a flabby dilated gall-bladder without calculi and little if any evidence of inflammation; as this negative finding may result in nothing further being done, it is important to note that removal of the gall-bladder has been followed by freedom from symptoms. It is generally agreed that the gall-bladder, unlike the urinary bladder, never becomes entirely empty; in fact the only occasion on which Prof. WILKIE has encountered an empty gall-bladder was in a case with obstruction of both hepatic ducts at their junction to form the common hepatic duct (Fig. IV.). In the past the occurrence of "white"

bile in the dilated ducts of some jaundiced patients with obstruction of the bile-ducts was ascribed to failure of the liver to secrete bile-pigment, and, indeed, the explanation why in some instances, as in malignant disease of the head of the pancreas, the bile was tarry and deep in colour, whereas in others, such as gall-stone obstruction, it was white, has only recently been provided by PEYTON ROUS and MCMASTER. They find that it depends on the condition of the gall-bladder, a healthy one concentrating the bile to one-tenth of its volume, whereas a diseased gall-bladder cannot do so; this is illustrated on the accompanying coloured plate, and it is pointed out that the condition of the bile can be shown by cholecystography, the dark concentrated bile casting a definite shadow due to the contained sodium tetraiodophenolphthalein, whereas the white bile fails to stop the X rays. Experiments on cats, however, in Prof. WILKIE'S hands have shown that there is a limit to this concentration and that ligature of the common duct may be followed by distension of the whole biliary system, including the healthy gall-bladder, with white bile; this observation raises the obvious question as to the explanation of the divergence from ROUS and MCMASTER'S results. A clear account summarising the present state of knowledge about the aseptic formation of the cholesterol "solitaire" and the septic formation of multiple calculi is given, and the way in which an aseptic cholesterol calculus, which often remains "silent" for years, may nevertheless obstruct the exist from the gall-bladder, favour infection and the formation of "a combination" calculus and numerous secondary septic calculi, is illustrated (Fig. VI.). This process is of practical importance, for in acute obstructive cholecystitis the surgeon should not be content to evacuate pus and numerous small calculi, but must also look for and remove the ovoid combination stone from the neck of the gall-bladder or the cystic duct.

SCHOOL CLINICS.

TOWARDS the end of last century the public conscience was more or less awakened to the unsatisfactory condition of elementary school-children, and since that time, as Sir HUMPHRY ROLLESTON points out in the address which we publish on page 687, there has been a remarkable extension of medical activity. By the Education Act of 1907 local authorities were obliged to inspect their school population, and by that of 1918 they became responsible for the treatment of defects as well. The earlier clinics were no more than clearing-houses, the children being directed to the appropriate places for their treatment; but as the cases were followed up it soon became evident that facilities for dealing with common conditions were often quite inadequate. The available agencies for treatment were private practitioners, provident dispensaries, voluntary hospitals, and Poor-law institutions, but without reorganisation these could not possibly cope with the number and types of defect which inspection revealed. Many authorities evolved far-reaching schemes, and by 1910 the London County Council had made arrangements with seven hospitals for treating 12,700 children. Later on, with the help of local committees of practitioners, it became possible to start a series of treatment centres, whilst still making full use of hospital resources, and in 1925 the number of children treated in London was nearly a quarter of a million.

The new clinic at Birmingham, whilst important, is only one of many similar institutions being opened all over the country, and clearly these are going to be of very great importance in preventive medicine. The public health demands the care of children from conception to maturity; they have to be thought of in relation to heredity, home surroundings, school curriculum, school environment, hygiene, and diet. These considerations are ever behind maternity and child welfare schemes, school medical work, factory inspection, and panel or hospital practice—all of which are rapidly being coördinated to serve the one end without overlapping. As now constituted, school clinics meet the need for treatment and secure it for defects and diseases hitherto largely neglected. Regularity of attendance can be maintained, and there is increasing coöperation with local practitioners. So successful have their efforts been that "the modern tendency," to quote a recent book on school hygiene,[1] "is to increase the number of these centres rather than extend the scope of hospital work, experience showing that the treatment centres possess greater elasticity than the hospital and lend themselves in some respects more readily to the needs of the education authority."

More and more the clinic forms a link between the child, its home, its school, and the medical officer. The presence of parents and the visits of nurses and health visitors to the children's homes make it a social and educational agency of great value. The requirements of particular districts must needs vary. In the country it may be hard to arrange for the care of scattered populations, but there is scarcely any well-planned scheme of treatment that will not fully repay the money spent on it, and in some areas difficulties can be met by fitting up motor wagons for dental, aural, or ophthalmic work. At Nottingham an institution of ambitious design has recently been opened under the direction of Dr. E. M. WYCHE, and here, besides the usual facilities found in large clinics, there is an operating theatre for tonsils and adenoids, with two wards, and general and private rooms for a staff of clerks and ample accommodation for nurses and caretakers. The new building opened by Sir HUMPHRY ROLLESTON at Birmingham, besides having admirable facilities for medical, dental, and special treatment, is also to be used for lantern and cinematograph lectures and for public meetings designed to quicken interest in preventive hygiene. Such public interest is exceedingly desirable, and, thanks to the work done by medical officers, it is steadily being aroused.

RIVERS POLLUTION.

AT the end of August the Standing Committee on River Pollution presented its third report to the Minister of Agriculture and Fisheries. It was a gloomy document. The Committee stated that the deeper it delved into the problem of pollution the more complex that problem appeared. After commenting on the general difficulty of reconciling the various interests of industry, water-supply, water power, fisheries, and local amenities, the report deplored the lack of scientific knowledge necessary to devise methods of dealing with particular effluents. Beet sugar manufacture, it appears, has introduced a fresh danger. This new industry requires large quantities of water; factories are consequently erected close to streams, and the factory effluents cause injury to stream life either by direct poisoning or by developing a mass of sewage fungus or by both means. The Committee recalled the recommendation of the Royal Commission on Sewage Disposal, advocating the creation of some central authority to hold the scales evenly between the

[1] Crowley's Hygiene of School Life, sixth edition, p. 186.

various interests involved and the establishment under such authority of a sufficient technical staff to find answers to the scientific questions which arise. The Committee's report solemnly warned the country that the longer it postpones a comprehensive effort to tackle the problems of pollution the more difficult and expensive will be the task and the greater the risk of failure. The same topic occupied the attention of the National Association of Fishery Boards at its annual meeting this year when the Ministry of Agriculture and Fisheries was asked for any available information. The Ministry's representative discussed the possibility of a general survey of the rivers of the country, but admitted that rivers were being destroyed by pollution meanwhile. He was unable to report any progress in the purification of a number of specified effluents; he announced that experiments proved that all road dressings containing tar were injurious to fish, and he spoke a little vaguely of the need of creating such a public opinion that something would have to be done. Of efforts in this direction much may be hoped of the recently founded Pure Rivers Society, which intends to educate the public, to collect practical, scientific, and legal information, and to band together all the different classes of the community which suffer from river pollution. The Society laments the official admission that pollution, instead of being checked, is making progress, and it criticises the weakness of the law.

The inadequacy of the law, however, seems due not so much to the failure of Parliament and the judges to give a remedy as to the difficulty of stimulating the proper persons and bodies to ask that the remedy be applied. Quite apart from any statutory prohibition, all interference with water flowing in a defined channel which injures its purity or volume is in England a nuisance at common law. Aggrieved persons can obtain damages and an injunction to restrain continuance; action can also be taken on behalf of the public, and, as pollution to the danger of health is an indictable nuisance, the Attorney-General can be moved to institute a prosecution. But although the law-courts have readily upheld the common law right to unpolluted water, the right could be defeated formerly by Act of Parliament or prescription. If the pollution had gone on long enough the offender acquired a prescriptive right to continue his offence. The acquisition of this prescriptive right, to which we shall presently return, carried with it no right to increase the pollution; but, with the gradual increase of populations and of manufacturing activity, it proved a serious limitation on the right to pure water. Fifty years ago Parliament intervened. The Public Health Act of 1875 made it the duty of local authorities to protect water-courses from sewage pollution. In the following year came the first Rivers Pollution Prevention Act. The 1876 Act, which piously recites that it was "expedient to make further provision for the prevention of the pollution of rivers and in particular to prevent the establishment of new sources of pollution," began by making it an offence to put solid refuse, waste, or any putrid solid matter into a stream so as to interfere with its due flow or to pollute its waters. It went on to prohibit the drainage into streams of solid or liquid sewage matter and of poisonous, noxious, or polluting liquids from factories or mines. But just as the railway and steamship interests have fought recently for exemption from the proposed legislation as to smoke abatement, so in 1876 the mining and manufacturing interests procured important limitations on the right to institute proceedings in respect of river pollution. In so far as it was left to sanitary authorities to take action, these bodies often combined the dual rôles of poacher and gamekeeper, and were themselves the worst offenders. In 1888, when county councils were first formed, the county council was authorised to enforce the Rivers Pollution Act. In 1893 a second Rivers Pollution Prevention Act added that where any sewage matter falls, flows, or is carried into a stream after passing through a channel which is vested in a sanitary authority, the sanitary authority shall be "deemed to knowingly permit the sewage matter so to fall, flow, or be carried." More recently the Salmon and Freshwater Fisheries Act of 1923 authorised fishery boards to take action to enforce the Rivers Pollution Acts and to aid any person or body in this connexion. Though Section 8 was retrograde in favouring existing pollution and in limiting the general right to prosecute cases of discharge of noxious trade effluents, the 1923 Act repeated previous prohibitions of the poisoning of fishing rivers. But this sequence of statutes has failed to effect its purpose. Litigation costs money, and vested interests are strong; neither individuals nor groups of ratepayers are ready to fight the large and wealthy corporations which are often the offenders. On the whole the landowner makes the best plaintiff because the law-courts have always respected his common law right to pure water; the local authorities have more scope when it is a question of enforcing statutory prohibitions. A few years ago a most hopeful success was won when the Court of Chancery allowed the common law right to be reinforced by the statutory prohibition. This was the decision in Hulley *v.* Silversprings Bleaching Co., [1922] 2 Ch. 268. A riparian owner had brought an action against a bleaching and dyeing company upstream to restrain it from continuing to pollute his water. The main defence was a plea of a prescriptive right to pollute, enjoyed for 20 years as of right; alternatively a right was alleged by virtue of a lost grant. Mr. Justice EVE upon this point declared that the prescriptive easement claimed was contrary to the Rivers Pollution Prevention Act of 1876, Section 4 of which made this pollution a criminal offence. "A lost grant cannot be presumed where such a grant would have been in contravention of a statute; and, as title by prescription is founded upon the presumption of a grant, if no grant could lawfully have been made, no presumption of the kind can arise and the defendants' claim must fail." This important decision went far to kill the defence of prescriptive right, and it is surprising that it has not been more freely turned to account.

We noted last year that in his annual report to the Metropolitan Water Board Sir ALEXANDER HOUSTON still regarded the Thames as a potential salmon river. It is well aerated at Hampton at all seasons of the year; only in the lower reaches is there the deficiency of oxygen which is fatal to fish life. Sir ALEXANDER HOUSTON's report for the present year tells something of the romance of the New River, a 300-year old stream gently flowing into the heart of London, for many miles in an uncovered channel, its water (save for chlorination) almost untreated and used to its utmost drop for drinking. Sir HUGH MIDDLETON, the famous author of this remarkable enterprise, found at first—as is stated in the charter granted to the New River Company in 1619—"the success thereof doubtful and the oppositions made against it very strong." Some of his persistence is required to-day. Two famous southern rivers, the Test and the Kennet, have been successfully protected from fouling, but it has been said that almost all the other rivers in Great Britain are illegally polluted. The fisherman's is not the only point of view, of course, but the ideal of a tidal Thames, purified to allow the ascent of the salmon and the descent of the smolts is one which not only fishermen hope to see realised within their lifetime. The state of the law must be investigated and improved. Public opinion must be organised against the contamination of rivers so that prosecutions can be undertaken with a prospect of substantial penalties, and so that industrial concerns can be driven to find means of purifying their noxious effluents. Important companies have, in deference to popular feeling, abandoned the desecration of local amenities by advertisements which offend the eye. They must be induced to feel the fouling of streams and rivers a far more serious offence. Meanwhile the Ministries of Health and of Fisheries must somehow mobilise research workers to find practical and not too expensive methods of treating effluents which at present defy scientific purification. Even in the present state of scientific knowledge there is constant pollution because towns neglect or misunderstand the expensive

and elaborate provision which their sewage works already contain. The Royal Commission on Sewage Disposal, whose recommendations seem to have been entirely ignored, reported that the purification of trade effluents by the local authority is practicable "in the great majority of cases."

Annotations.

"Ne quid nimis."

SIR JOHN MACALISTER.

Sir John MacAlister, alike by his strenuous work and his sympathetic personality, so impressed himself upon the regard and affection of a very large range of medical men that it has been a natural idea on the part of his family to compile for private issue a small volume in his memory. The volume is not, and is not intended to be, a biography, though the history of his life emerges from the large assortment of obituary notices published in the general and medical press and the library periodicals which form the bulk of the compilation. These notices are supplemented by a collection of resolutions from various public, medical, and literary associations, and by extracts, signed and unsigned, from numerous letters of sympathy of a personal character. The little volume, which contains several excellent portraits, will fill exactly the purpose which the family had in mind. It is a tribute from all sorts and conditions of men who were brought into contact with John MacAlister's work, leisure, and aspirations which his friends will be glad to possess.

SUBMAXILLARY SALIVARY CALCULUS.

THE removal of six faceted stones from the submaxillary gland, recorded by Mr. W. I. Daggett in our last issue, is an interesting addition to the literature of salivary calculi. This form of stone, which Hamilton Bailey aptly calls[1] "the Cinderella of the stones to which human secretory and excretory mechanisms are heir," is not uncommon, though the relatively minor disabilities to which it gives rise in comparison with other varieties of calculus have detracted from its surgical importance. Yet both in regard to size and to the remarkable way in which the six stones fitted one another Mr. Daggett's case is unusual. By a striking coincidence Sir James Berry, in the *British Journal of Surgery* for April, has recorded a case of submaxillary calculus which had undergone spontaneous fracture into three pieces with eburnation of the broken surfaces. The question naturally arises whether this case might also be looked upon as one of three calculi with faceted surfaces, or, conversely, whether Mr. Daggett's example might not be one of spontaneous fracture with eburnation of the surfaces. The answer is not easy. If it is difficult to imagine spontaneous fracture of a calculus in the gland, unless there was some definite history of injury which might render it possible, it is also difficult to envisage the conditions which could lead to the formation of several stones in different parts of the gland, with intervening gland tissue which gradually became destroyed, as Mr. Daggett suggests. Until we know the actual cause of the formation of calculus in the salivary duct or gland such aberrations of the usual type of stone as this must remain pathological curiosities. It is noteworthy that in Mr. Daggett's case there was a history of 18 years' development, while in Sir James Berry's case there was evidence to show that the condition had been developing over a period of 29 years. The absence of symptoms in the latter case is in striking contrast to the former in which the periodic swelling and pain with inflammatory changes were in accordance with the text-book description of the condition.

TRYPARSAMIDE IN THE TREATMENT OF NEUROSYPHILIS.

THE new arsenical compound tryparsamide has now been tried for the treatment of syphilis, and particularly neurosyphilis, in many countries. Observations have been published by workers in France, Germany, and the United States, and we print this week a detailed report by Dr. J. D. Silverston to the Medical Research Council of his experiences with the new treatment at the Whittingham Mental Hospital, Preston, and an abstract of a report by Dr. M. Brown and Dr. A. R. Martin to the Glasgow District Board of Control. Extensive trials made at the Mayo Clinic, Rochester, U.S.A., were put on record by J. H. Stokes and L. F. X. Wilhelm two years ago, and P. A. O'Leary and Becker, who continued their work, were able in March last to include observations on 207 patients, of whom 113 had received at least two courses of tryparsamide each consisting of ten injections. In their 50 cases of early general paralysis, treated with the new drug with the addition of mercury or bismuth, 12 per cent. showed definite remissions —a figure, they point out, not appreciably higher than the proportion of spontaneous remissions; 66 per cent. of their patients were better in one or more ways, some of them only subjectively. Improvement in the state of the blood and cerebro-spinal fluid as judged by specific reactions occurred in 32 per cent., and in 20 per cent. the spinal fluid reactions became normal. These serological effects were more marked the more prolonged the treatment, and in a number of cases tryparsamide produced definite serological improvement when other preparations had failed to do so. In fact, it seemed that tryparsamide was beneficial chiefly as a "finishing-off" remedy after courses of treatment with other drugs, for when it was given alone to patients who had had no previous antisyphilitic treatment only five out of 35 showed any response. O'Leary and Becker group in a separate class 15 cases of G.P.I. without paralytic symptoms; in one of these patients the cerebro-spinal fluid became negative to specific tests, but in the others there was little improvement except such as resulted from the general tonic effect of the drug. In cases of tabes dorsalis the results were disappointing; the promise of relief in gastric crises held out by certain observations of Stokes and Wilhelm was not fulfilled. In 14 cases of disseminated sclerosis and of combined sclerosis the new treatment was without benefit. Dr. Silverston has not so many cases to record, but his observations include patients in whom tryparsamide was used as an adjunct to treatment by malaria, and he is able to compare groups treated by tryparsamide without and with fever treatment. The former comprised eight cases of G.P.I., and of these two, which were early cases, showed complete remission. In one of them after 20 injections the Wassermann reaction became negative in the blood and cerebro-spinal fluid and the colloidal gold reaction became normal, but in the other the Wassermann reaction remained positive in both fluids and the colloidal gold reaction was little changed. Of the seven cases treated with tryparsamide after malaria two again were early cases, and both showed clinically complete remission of the disease, while one more advanced case improved. Neither the clinical nor the serological results are considered by Dr. Silverston any better than those obtained by malaria alone. With more advanced cases of the disease the treatment presented difficulties and was disappointing. Of the 13 cases of neurosyphilis treated at the Gartloch Mental Hospital by Dr. Brown and Dr. Martin under laboratory control with a full course of tryparsamide alone, all except two benefited in some degree; five steady and useful workers were able to return to their homes. Three other advanced cases died during the treatment but no toxic disturbances were noted and gain in weight was the rule. At the Pretoria Mental Hospital, Dr. A. Pijper and Dr. E. D. Russell have found [1] a combination of

[1] South African Medical Record, April 24th, 1926.

tryparsamide and mercuric salicylate effective in cases of early paresis and tabes.

The use of tryparsamide is not free from untoward effects, to which several writers have called attention, the most serious of these being visual impairment, transient or permanent. It is often difficult, however, to decide in what degree this impairment is to be attributed to the syphilis and in what degree to the drug. O'Leary and Becker recorded visual defects during treatment in 10·6 per cent. of their patients with objective findings in the fundi in 4·3 per cent. and persistent functional impairment in more than half of these. Their experience is that even subjective defects, without apparent changes in the fundi, are not to be lightly regarded. In Dr. Silverston's cases four patients out of a total of 20 complained of dimness of vision, and in one of them a slight defect became permanent. It would appear from comparison of the reports up to date that for the majority of cases tryparsamide has no proved advantage over the more tried arsenical compounds. Tryparsamide injections are available for those not suited to the risks of malarial treatment, but the visual complications offer a hazard which it has not been possible to obviate.

DULL AND BACKWARD CHILDREN.

EDUCATIONAL authorities in different parts of the country are showing themselves alive to the importance of the problem of dull and backward children, as distinct from that of mentally defective children, for whom legislative provision has been made, and for whom also educational opportunities are in many areas available. The County Borough of Huddersfield has issued an account of an inquiry by its medical officer, Dr. S. G. Moore, into this problem. He took as the subjects of his inquiry all children who were one or more classes behind others of their age, constituting, as he found, 3·14 per cent. of the total number of children in the schools. This figure is considerably below the 10 per cent. suggested by estimates and actual inquiries in other areas, and it is probable that a large number of backward children have been missed, who, owing to the prevalence of the system of promotion by age, irrespective of merit, are actually working in the classes of the average children of their own age. The object of the investigation was to determine how far backwardness was due to inherent dullness, and how far to other causes—physical defect or disease, irregular attendance at school, faulty grading, mental attitudes to school and teacher. Dr. Moore used the Stanford-Binet scale of intelligence tests, and his results are somewhat startling, for they show, taking an intelligence quotient of 90 as a lower limit of normality, that, out of 288 children examined, 184 were either normal or actually superior in intelligence. It is generally recognised that among these children educational deficiency is greater than intelligence defect, but Dr. Moore's figures are so striking as to suggest either some flaw in our educational methods or in our means of testing intelligence. Dr. Moore employed a further test, apparently designed by himself, to try "the power of the child to recognise incongruities and the proportional relationships between two or more related things." He does not state the nature of the test, but if it has not been itself previously tested and standardised by trial upon normal children, it is not convenient to make it the basis of a conclusion so contrary to general experience as he does—viz., that out of 288 backward children examined, the backwardness of only 6 was accounted for by inherent mental dullness. The others are explained by either personal bodily condition or environment, but it is pardonable to doubt whether defective eyesight, for instance, unless of high degree, is in itself ever a potent cause of backwardness, or whether a general condition of ill-health, such as malnutrition, is so much a cause of backwardness as it is along with backwardness a result of an inherently feeble stock, physically and mentally. In some quarters there is a tendency to exaggerate the rôle of heredity. Dr. Moore tends to the other extreme, and as far as can be seen from the data in this report, on inadequate grounds. His protest against too early labelling of children as "inferior" or "deficient" will elicit much sympathy, but that is scarcely sufficient reason for denying to these children the benefit of the special teaching they require. The less backward cases might, as he suggests, be dealt with by correct grading in the standards, but the needs of the more severe cases, as of the feeble-minded, can only be adequately met by classes and schools with special curricula.

ALIMENTARY HYPERGLYCÆMIA.

IN our issue of Sept. 18th we published some interesting observations by Dr. C. D. Shapland on the effect of the ingestion of cane-sugar on the blood. The subject is of such importance that all new observations are worthy of record and close study. The alimentary glycosuric test put forward in 1885 by Corlat for a long time held the field as a means of investigating hepatic glycogenesis, but has been superseded by the test of alimentary glycæmia brought into notice in 1908 by A. Gilbert and A. Baudoin. Further experiments have lately been published[1] by Dr. P. Introzzi, of Pavia, which have brought some interesting facts to light and supplement those of Cammidge, H. Gray, and others. The method employed was to give the patient fasting in the morning from 40 to 100 g. of sugar (glucose, lævulose, or lactose) dissolved in 100–200 c.cm. of water, having previously taken some blood from the finger for examination. Further samples of blood are taken regularly at half-hourly intervals for four hours, the patient being kept in bed and without food. It is thus possible to obtain a curve indicative of the glycæmic reaction composed of an ascending phase, a descending phase, and sometimes of a plateau placed between these two. The typical curve which is observed in a healthy individual shows that the saccharine content of the blood, temporarily modified by the administration of even a small quantity of a monosaccharide, promptly regains equilibrium after a phase of rapid ascent, reaching a moderate height always in relation to the amount of sugar taken after 30–40 minutes. This is preceded by a phase of descent also rapid, followed, however, by a brief phase of hypoglycæmia, after which the saccharine content promptly returns to its primary value. The total duration of the reaction should not exceed two hours, in which time the glyco-regulating mechanism, if it is functioning normally, should rapidly free the organism, or rather the blood, from an invasion of sugar which would keep it in a state which is not normal. If the phase of ascent in the curve is prolonged to excess, if the summit is too high or with a plateau, if the descending phase is too slow or with a phase of hypoglycæmia out of proportion to the hyperglycæmia, if there are marked oscillations or the total duration of the reaction is unduly long, that is evidence of some insufficiency in the glyco-regulating mechanism. In the cases examined by Dr. Introzzi were included affections of the liver, of the thyroid, and mild diabetes, and they all showed in a more or less striking manner, when submitted to the test of hyperglycæmia, a deviation from the normal carbohydrate metabolism. In liver disease in general the glycæmic content while fasting was not above normal (1 per 1000), except in one case of large syphilitic liver with splenomegaly and one of chronic jaundice and ascites from a tumour of the head of the pancreas, in both of which the content was 1·36 per 1000. In affections of the thyroid (Basedow's disease and simple goitre), the values found were not above normal. Thus a normal content during fasting does not exclude a potentially compromised glyco-regulating mechanism, while marked deviations from normal are always found by the

[1] I Problemi della Nutrizione. Giornale di Fisiopatologia di Clinica e di Dietetica. Rome. February–May, 1925.

test of induced hyperglycæmia. Usually when the glycæmic curve is changed by glucose, it undergoes the same modification with lactose and lævulose, but the oscillations caused by the latter monosaccharide conform more to the normal. The renal permeability was found to vary, in one case reaching 2·30 per 1000, without any glycosuria ensuing; the threshold of renal permeability for lævulose, however, was found to be lower than for glucose and lactose. The study of glycæmic curves may be of considerable importance in morbid conditions characterised by hepatic lesions as a possible means of estimating the degree of functional alteration of the organ, and these observations of Dr. Introzzi are a valuable contribution.

THE ADULTERATION OF FOOD.

Mr. G. D. Elsdon, Lancashire county analyst and formerly Salford Borough analyst, has published some interesting notes on food adulteration as an addendum to his report for 1925 to the Salford Health Committee. The series of Acts now regulating the purity of food began with the Food and Drugs Act of 1875, which, with modifications and supplements, is still the main provision against sophistication. Local authorities taking proceedings under this Act are apt to find it hard to prove their cases; on questions of fact the evidence of inspectors or analysts is usually accepted, but questions of trade uses and public requirements are frequently brought forward by the defence, which often has large sums of money placed at its disposal by commercial organisations. The subject of "trade custom," says Mr. Elsdon, is one of great urgency and importance, since it recurs again and again where manufacturers are placed on their defence by charges of adulteration. Many interesting examples of prevalent practices are given in the report. The mixing of a small quantity of butter with margarine does not affect the flavour, Mr. Elsdon considers, and is only done so that the public may be encouraged to buy some particular article and that the use of the word "butter" may be justified. As to jams and marmalade, some half dozen of the larger firms and a few of the smaller ones do produce a genuine article, but, generally speaking, fruit pulp, fruit substitutes, glucose, pectin, gelatin, agar-agar, and artificial dyes are more in favour with the "preserve manufacturer" than fruit itself. In a recent correspondence in the *Times* it was suggested that so-called improvement by the admixture of "a little pure fruit juice" is justifiable because jam made from certain fruits, such as strawberries, is too fluid for the popular taste without some jellifying addition; but there is no doubt that often this specious phrase covers deplorable adulteration. Of flour, Mr. Elsdon says that "it is no exaggeration to say that the present position of the flour-milling industry in England should not be tolerated in any civilised country, whilst at the same time it may be admitted that only in such a country would adulteration of this type be attempted." He remarks that the use of alum to produce a white loaf is nowadays not at all common, though ozone and chlorine are being used to some extent. One form of adulteration which is now largely if not universally practised is the addition of so-called improvers to flour. An improver may be simply a substance to lighten the colour of the flour or of the finished loaf, or it may be used to produce more loaves per sack, by making the dough absorb more water. At first calcium phosphate was the substance used as an improver, but, Mr. Elsdon states, "more objectionable still are the newer forms of adulterant. A very large percentage of flours now contain persulphates, peroxides, and other compounds, which are allied to the so-called oxygen compounds used in the modern laundry. Their use should be prohibited. It can only be repeated that the bulk of the flour sold in this country to-day is seriously adulterated to the great detriment of the purchasing public." Mr. Elsdon says that probably no kind of food is more adulterated than the so-called temperance drinks, fruit cordials, and similar preparations, whilst his comments on medicated wines will confirm the opinion of those who prefer to take their wine, their meat juice, and their medicine out of separate glasses.

CONGENITAL OCCLUSION OF POSTERIOR NARES.

CONGENITAL occlusion of the posterior nares is a condition which presents itself every now and then to the rhinologist. Outside its clinical bearing and its associated relations little is definitely known about it; only two examples of the true affection seem to have come to autopsy, and only one of these has been treated by maceration. Prof. J. E. Frazer, in opening a discussion at the Post-Graduate Hostel in the Imperial Hotel on Sept. 21st, dealt shortly with the probable origin of the malformation in the course of an address on the Clinical Bearings of Embryology. The nasal fossæ, as he pointed out, during development increase their height in an upward and backward direction, and not downwards; in this growth the primitive posterior nares lengthen upwards, keeping pace with the increasing height of the fossæ, so that they finally extend from just above the premaxillary level to that of the highest part of the roof of the mouth cavity. The bucco-nasal membrane is stretched and ruptured in the growth. The lower and greater portions of these elongated openings are then closed by the palate folds, the unclosed portions forming the definitive choanæ. As the fossæ grow upward in the mesodermal bed, that part of the tissue which remains between them forms the septum, and the posterior edge of this is the part of the roof of the mouth left between the two openings, to which the palate folds have attached themselves. The presence of congenital stenosis or occlusion is best explained, in Prof. Frazer's view, by assuming that the upgrowth of the posterior opening on the side affected has not taken place in keeping with that of the fossa itself. The part of the mouth-roof concerned is formed of visceral mesoderm, derived from the maxillary process and forming a layer on the buccal surface of the paraxial mesoderm in which the fossa is embedded. Normally this visceral mesodermal layer is split by the ascending opening, and is deposited on the septum and on the outer wall of the opening; the vomer is formed in this mesoderm where it covers the back of the septum. When the layer is not opened out, but remains as a postero-inferior wall to the fossa, its mesoderm contains potential bone, belonging to the vomerine system, spread out within it. Bone is therefore to be expected in the formation, continuous with the front and upper part of the vomer. When the palate fold closes across this plate it is necessarily fairly closely apposed to it, but is only attached near the middle line. After birth, however, the height of the vomer is increased by addition to its lower and back part, so that the palatine level is pushed away somewhat from the plane of the obstructing plate, which, with reference to the palate, can now be described as inclining downwards and forwards. It may or may not possess an opening in its lower and front part, representing the original and very slightly enlarged primitive naris, from which the bucco-nasal membrane has disappeared. Sir James Dundas-Grant, who was in the chair during the discussion, spoke on this subject, and confirmed the existence of bone, which is, we believe, usually present in these formations.

BARON LARREY.

IN the *Military Surgeon* for September Captain James D. Edgar, late of the United States Army, gives an account of Dominique Jean Larrey, who was the first Napoleon's principal medical officer, and initiated modern methods of handling and evacuating war casualties. Before his time the wounded were indeed collected and dressed at once on the field, but the ambulances, heavy vehicles with 40 horses, were left behind before battle, and only reached the front after one or two days, when further time was lost

in the journey back to the surgeons and hospitals. Larrey saw that this delay meant death to many. Using as his pattern the light guns or *artillerie volante*, he devised *ambulances volantes*, small wagons with large springs and stuffed mattresses, drawn by two horses (for two lying patients or four sitting) or four horses (four lying or eight sitting). These could come up to the firing-line, and even accompany cavalry, and they carried medical staff and dressings to the line. The wounded were now collected, dressed, and taken at once in ambulances to the surgeon at what we would call the main dressing station; they were operated on very early, and then conveyed quickly to hospitals three to ten miles in the rear, where they were all in bed within 24 hours, even after the great battle of Austerlitz. There was less suffering, he discovered, in rapid evacuation than in confinement in crowded hospitals. Larrey also improved treatment, recommending that the skin round wounds should be kept very clean, that salt and chlorinated soda solutions should be used instead of ointments in the treatment of wounds, and that dressings should be done as rarely as possible. His chief insistence was on the urgency of amputation where it was required, and it is now clear why this promptness would prevent tetanus, as he asserted. Resections, he considered, should be done instead of amputations wherever possible. He found blood-letting uniformly disastrous, and blisters of no avail—the raw surface, moreover, being liable to moist gangrene—and insisted, Hippocrates notwithstanding, that wounded men require a generous diet. Larrey was much beloved by the soldiers, and treated French and enemy wounded equally; it is said that this practice saved him when he was captured by the Germans after Waterloo, and sentenced to be shot. Recognised by a German doctor, he was taken to headquarters and released by Blücher whose wounded son he once had saved. After Austerlitz Napoleon had made him Baron Larrey, giving him a pension of £200 a year, and after Waterloo he continued to be much respected, being made surgeon of the Royal Guard and having his pension restored. When he visited London in 1826 he was cordially received by the English medical profession. At the age of 76 he inspected the French hospitals in Algeria, but contracted pneumonia on his return to France, and died at Lyons in 1842. He was buried in Père la Chaise in Paris, and his name is on the Arc de Triomphe. Napoleon, in his will, left him 100,000 francs, as "the most virtuous man I have ever known," and in French, as Captain Edgar points out, the word "virtuous" means more than in English, for it conveys the idea of bravery and utility to the State. In the old days Baron Larrey used to be quoted as proof that France recognised more generously than England the services of her doctors, but he had a specially great opportunity and used it magnificently.

THE GARDENS OF MADEIRA.[1]

IN an interesting little publication, Dr. Michael Grabham assumes the mentality of the British tourist as receptive and intelligent even if uninstructed, and proceeds in friendly vein to identify for him the more prominent features in the Madeira flora, if with special reference to gardens still with wide notice of general botany. The book is certainly an invitation at this period of the year, for those who can accomplish such charming plans, to sojourn in Madeira round about Christmas time. When shortening days here give a foreboding of the approach of winter many who know the rigors ahead, with which they can cope only miserably, will feel tempted to resort to an island where "Spring is perpetual and Summer occurs in alien months." Dr. Grabham reminds those in charge of such patients that the transit from winter to summer conditions can now be made with complete comfort in less than three and a half days, and we learn that the visitor arriving at Christmas will find flowers which we associate with spring and early summer blooming in full profusion and occurring promiscuously with the numerous conspicuous and fragrant plants indigenous to Madeira, which in this country decorate glass-houses or make but a transient appearance in the open. Mid-winter vegetables continue their autumnal yield through December and January, and green peas and cauliflowers have become abundant. Speaking from the botanical point of view, he notices that in general character the flora of Madeira confirms the rule relating to an insular collection, showing many orders with one genus only, and genera with a solitary species. Analysis of the comprehensive flora of the island has been due to the descriptive and identifying work of British botanists, and a comment on the profusion of specimens as well as upon the easy circumstances of growth and reproduction is furnished by a semi-apologetic phrase in which Dr. Grabham confesses that his plan for taking the garden flowers in monthly sequence has been baffled by "the exercise of a perverse exuberance in the genera, and a tendency to transgress all limits and break forth anew in unseasonable revivals."

CHINA MEDICAL ASSOCIATION.

IN spite of the political situation the China Medical Association held its eighteenth Biennial Conference at the beginning of this month in Peking. Since the last of these conferences the Association has dropped the word "Missionary" from its title so as to become more representative of medical interests in China, and the broadened basis has brought an increase of membership. Those who administer its affairs are doing good work under considerable difficulties, and during the past year or so these have been increased by the enforced invaliding from China of the President and Vice-President of the Association and the Editor of its journal. Missionaries seldom have large financial resources and the Association is without any endowment fund. It would hardly have been possible to carry on the work at all but for assistance from the China Medical Board of the Rockefeller Foundation, which during the past five years has contributed 25,000 dollars towards its expenses. Unfortunately, the period of this grant now comes to an end, but the successful record of the Association's work should strongly recommend renewal of the subsidy. Even the précis of papers read at the Conference make it obvious that really valuable work is being done in various parts of China by members of the Association, and the programme shows that they have an efficient organisation; the *China Medical Journal*, which records their research and opinions, has become familiar throughout the world. At the suggestion of the Association the various medical societies of China have formed a joint council which is working for public health, and the courageous way in which the immense sanitary problems of that country are thus being faced makes it reasonable to hope for important if gradual reform.

ON SUSPICION OF RABIES.

OUR medico-legal correspondent on page 724 tells of a dog which was clubbed to death a fortnight ago at Balham on a suspicion of rabies and he queries whether police officers are properly instructed to deal with such an occasion. The larger question arises whether it is now reasonable for anyone in this country to suspect an animal of having rabies. With the exception of Australia this infectious disorder of animals is to be found in all parts of the world, although, as we are reminded in the most recent monograph [1] on the subject, the number of cases

[1] Lyssa bei Mensch und Tier. By Prof. Dr. R. Kraus, Dr. med. vet. F. Gerlach, and Dr. F. Schweinburg. Berlin and Vienna: Urban and Schwarzenberg. Pp. 464. M.30.

has greatly diminished in civilised countries in comparison with earlier times when epidemics were frequent. The Netherlands have, in fact, recently become quite free. Great Britain in 1895 had to record more than 600 cases in 30 counties, and it was only the quarantine for which the late Lord Long was so cruelly abused which rid us of an anxiety ever present in countries where dogs and human beings live in close proximity. From 1903 on Great Britain was free from rabies, and the relief would have remained complete had it not been for the thoughtless or criminal evasion of quarantine regulations by those who reached this island by sea or air. In 1918, as the result of an outbreak in Devon and Cornwall, introduced by aeroplanes reaching Plymouth, 30 persons were bitten by dogs ascertained to be rabid, and in the following two years 150 cases were notified from 14 counties and 33 from 9 counties, so that the Ministry of Health felt itself obliged to set up a number of centres at which Pasteur treatment could be initiated without delay. In the House of Commons at that time Sir A. Griffith-Boscawen remarked that dogs suffering from rabies had been known to wander great distances from their homes, although the farthest recent excursion was one of 50 miles. The incubation period in one case was as long as seven and a half months, although the disease did not occur in any dog following release from its six-month quarantine, and the Ministry of Agriculture then and since was satisfied that existing regulations are adequate. Happily, since 1921 this country has remained completely free from imported rabies, and while the smuggling of dogs must still be regarded as a conceivable possibility, the risk of reintroduction of the disease should be very small indeed.

WHAT IS A SAUSAGE?

THE answer of the Edinburgh city analyst, Mr. A. Scott Dodd, to this conundrum is "a bag of mystery." In examining 50 samples of sausages made in various parts of the country Mr. Dodd found that the moisture varied from 31·2 to 58·2 per cent.; the fat from 7·0 to 42·9 per cent.; the starch, flavouring, &c., from 5·3 to 33·7 per cent.; the proteids from 5·6 to 12·9 per cent., and the meat from 29·6 to 80 per cent. During the meatless days of 1918 sausages were included in the Meat Rationing Order as meat, and the minimum quantity of meat was fixed at 67 per cent. for first quality and 50 per cent. for second quality sausages. Even in this Order, which has now been revoked, no distinction was made between fat and lean meat. In view of the possibility of sausages being made mainly of fat and "starch filler," Mr. Dodd thinks it would be advisable to limit the permissible proportion of fat. It would be impossible to determine accurately the proportion of liver, gristle, &c., but the proportion of nutritious fat-free meat may be satisfactorily deduced from the percentage of proteid nitrogen present, as gristle does not contain much nitrogen. As the result of his experience Mr. Dodd suggests the following standards: (1) sausages to be of two grades only; (2) first-grade sausages (to be indicated by a band and conspicuously labelled) to contain not less than 67 per cent. of meat, second grade not less than 50 per cent.; (3) fat to be included as meat but not to exceed half the total meat present.

Dr. Charles J. Martin (Director of the Lister Institute and Professor of Experimental Pathology in the University of London) and Sir Frederick G. Hopkins (Professor of Biochemistry in the University of Cambridge) have been appointed members of the Medical Research Council to fill the vacancies caused respectively by the death of the late Lieut.-General Sir William B. Leishman and by the retirement of Prof. T. R. Elliott.

ALTHOUGH arrangements for the coming session of the Royal Society of Medicine are not yet complete, there is every indication that it will be very successful. Besides the ordinary meetings of the sections there will be one special discussion on Blood-letting by the the Society as a whole, and ten discussions held jointly by two or more sections. The first social evening will be held on Monday, Oct. 18th, when the guests will be received by the President, Sir James Berry, and Lady Berry, at 8.30 P.M., and at 9.30 P.M. Sir Arthur Keith will give a short address entitled John Bull: a Study in Anthropology, with lantern illustrations. It has been found necessary to make a rule that guests at these receptions, unless accompanied by a Fellow, Member, or an Associate of the Society, will need an invitation card; this may be obtained by Fellows, Members, or Associates on application to the Secretary of the Society. The annual dinner has been arranged for Thursday, Nov. 18th, at 8 P.M., at the Hotel Victoria, Northumberland-avenue. The Prime Minister has consented to be the Society's guest of honour if his duties permit.

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Lts. H. M. Petty, F. M. B. Allen, and E. E. Henderson to be Surg. Lts.

ROYAL ARMY MEDICAL CORPS.

Col. E. T. Inkson retires on ret. pay.

Lt.-Col. C. C. Cumming to be Col., vice Col. E. T. Inkson, to ret. pay.

Maj. H. Harding to be Lt.-Col., vice Lt.-Col. C. C. Cumming.

The undermentioned Capts. to be Majs.: W. Bird (Prov.), A. C. Jebb, J. B. Minch, T. I. Dunn, C. Popham, A. J. O'B. O'Hanlon, W. G. Shakespeare (Prov.), O. C. Link (Prov.), E. E. Holden (Prov.), W. Campbell, W. H. Cornelius, R. G. Martyn (Prov.), N. Cameron (Prov.), C. F. Burton, S. D. Robertson, and R. H. Hodges (Prov.).

ROYAL ARMY RESERVE OF OFFICERS.

Lt.-Col. C. F. Wanhill, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

MILITIA.

Maj. R. Magill retires on reaching the age limit.

TERRITORIAL ARMY.

Capt. H. P. Gabb, from Active List, to be Capt.

Capt. J. S. Cooper having attained the age limit, is retd. and retains his rank.

Lt. C. C. Taffs is secd. under para. 137 T.A. Regulations.

W. H. M. Jones to be Lt.

ROYAL AIR FORCE.

Flying Officer D. Magrath is transferred to the Reserve, Class D.2.

INDIAN MEDICAL SERVICE.

Maj. C. R. O'Brien to be Lt.-Col.

Ephraim Benjamin to be Temp. Lt.

The King has approved the retirement of Lt.-Col. Padmâkar Krishna Chitale.

Summer Time, which commenced on April 18th, will cease on Sunday next, Oct. 3rd, at 3 A.M., when the clock will be put back to 2 A.M. The hour 2–3 A.M. summer time will thus be followed by the hour 2–3 A.M. Greenwich time.

KING EDWARD'S FUND.—This great Fund's twenty-ninth annual report, which has just been issued, shows that the income for the last financial year was £413,872, and the expenses £312,420. The receipts included £50,000 from the estate of the late Mrs. John Wells, and £85,000 from that of the late Lord Mount Stephen. The unexpended balance was placed to the Funds and Capital Accounts. Since the establishment of the Fund in 1897 the receipts have amounted to £8,846,357. Of this total the British Red Cross Society and the Order of St. John of Jerusalem have contributed £259,000, the Combined Appeal produced £395,000, and £383,000 has been provided by the League of Mercy. The distributions to hospitals, convalescent homes, and sanatoria for consumption come to £5,263,000, and the working expenses are less than 3½d. in every pound received.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXCI.—THE TREATMENT OF CHOLERA.

CHOLERA has been defined by Manson as an acute infectious epidemic disease characterised by profuse purging and vomiting of a colourless serous material, muscular cramps, suppression of urine, algidity and collapse, the presence of a specific bacillus in the intestines, and a high mortality. The passage of profuse colourless watery stools (often containing white flakes of denuded intestinal epithelium) accompanied by copious vomiting of watery fluid is pathognomonic of cholera. Later diagnostic signs are muscular cramps and suppression of urine, absence of the pulse at the wrist, cold and clammy skin, shrunken features, shrivelled extremities, and feeble, husky voice.

The golden rule for guidance of the practitioner in endemic areas and during epidemic times is that all diarrhœa accompanied by vomiting should be regarded as incipient cholera and immediately treated as such. Failure to appreciate the value of this rule has caused the loss of many lives. Since the patient's prostration is sometimes out of all proportion to the catharsis, cholera must be partly a toxæmia due to absorption of the toxins of the cholera vibrio from the intestines. But the collapse, suppression of urine, and subsequent uræmia are in most cases due to loss of fluid from the system, and if this loss of fluid is arrested collapse and other serious symptoms do not develop. This being so, the treatment of cholera naturally resolves itself into two stages: (1) the medical treatment of the stage of evacuation by intestinal astringents, with the object of arresting the diarrhœa and thus preventing the onset of collapse; and (2) the surgical treatment of collapse by intravenous saline injections in an effort to restore and maintain the circulation until the loss of fluid from the bowel naturally ceases.

As most cases of cholera, owing to the fulminating character of the disease, come under notice only when collapse has already set in or is impending, by which juncture the time for medical treatment is past, the great value of this treatment is not adequately realised.

The Stage of Evacuation.

For the treatment of cholera in the stage of evacuation the most popular and widely used of all remedies is opium, either alone or in mixtures with acids or carminatives. Doubts have frequently been expressed as to whether such treatment can cut short the disease, since it is impossible in any given case to declare that the disease would have developed into collapse had treatment been withheld. Some writers hold that the use of opium is dangerous, basing their arguments on the erroneous theory that opium is excreted by the kidneys. However, from records extending over many years of the results of treatment of a large number of cases of cholera in the endemic area of the Asansol Mining Settlement, it is now clear that opium combined with acids or carminatives is capable of cutting short the disease in the stage of evacuation in the great majority of cases. The mortality-rate in the mining settlement of cases of the fully-developed disease, most of them being collapsed, treated with such mixtures was only 50 per cent., compared with a *constant* annual mortality-rate of approximately 90 per cent. in wholly untreated cases. The great value of opium in the stage of evacuation of cholera was well summed up by the late Dr. A. J. Wall, who held—from a large experience of cholera in India and Europe—that if in the primary stage of the disease the evacuations are stopped the course of the disease will be stopped also, and that opium administered hypodermically before collapse has set in will in a large number of instances save the patient from this complication.

Drugs.

A doctor called in to treat a patient with cholera in the stage of evacuation should immediately give a hypodermic injection of morphia gr. $\frac{1}{4}$ c. atropine gr. 1/100. One of the antidiarrhœics mentioned below should then be prescribed and administered in the manner indicated.

℞ Sod. bicarb., gr. 15; creta preparata, gr. 15; spt. æther, ℥ 15; spt. ammon. aromat., ℥ 15; tinct. opii ammoniatæ, ℥ 30; aq. chlorof., ad ℥i. ℥i every 20 minutes until purging and vomiting have definitely ceased.

℞ Acid sulph. aromat., ℥ 15; tinct. camph. co., ℥ 30; tinct. chlorof. et morph. co., ℥ 5; aq. menth. pip. ad ℥i. ℥i every half-hour until purging and vomiting have definitely ceased.

Kaolin or China clay, known also as bolus alba, is a native white aluminium silicate, which in addition to being an intestinal astringent in large doses, possesses the property of adsorbing toxins from solutions, thus rendering them inert. It is used with great success in the primary stage of cholera—one ounce or more suspended in a glass of water being swallowed slowly by the patient every hour until diarrhœa and vomiting have ceased. Half doses are then continued every four hours during the succeeding 24 hours, and quarter doses subsequently until the risk of relapse is past—i.e., until the end of the third day.

I have reintroduced the use of the essential oils in the treatment of the stage of evacuation in cholera with much success in the form of the following mixture:—

℞ Ol. anisi., ol. cajaput, ol. juniper, āā ℥ 5; acid sulph. aromat., ℥ 15; spt. æther, ℥ 30.

Of this mixture half-drachm doses should be administered in an ounce of water every quarter of an hour for two or three hours, by which time all symptoms have usually disappeared. Doses vomited should be repeated. As the mixture contains no opiates it can be safely placed in the hands of any intelligent person for administration. For this reason it is particularly valuable in the treatment of cholera during epidemics when large numbers of cases have to be treated simultaneously. It is a powerful carminative, stimulant and astringent, quickly arresting diarrhœa, and thus aborting the disease. Relapses after its use are unknown, and no serious restriction of diet is necessary on apparent recovery.

The Stage of Collapse.

When owing to lack of treatment in the primary stage of the disease a dangerous amount of fluid has been lost from the system and collapse has set in, intravenous saline injections must be resorted to without delay if life is to be saved. It should be clearly appreciated that collapse from loss of fluid in cholera does not differ fundamentally from collapse from hæmorrhage, the principles underlying the treatment of the latter applying with equal force to that of the former. Success depends on the introduction of a sufficient quantity of fluid rather than on its quality. The rôle of intravenous saline injections in the collapse stage of cholera is purely symptomatic and non-specific—viz., to replace as often as may be necessary the fluid lost from the circulation until the violence of the attack has spent itself and the flux from the bowel spontaneously ceases. Repeated injections are in many cases necessary over a period ranging from two to six days. Owing to its protracted and exacting nature, the treatment of collapse in cholera is much less successful in private practice than in hospitals specially organised and staffed to carry it out assiduously.

Leonard Rogers, following Gaertner and Beck, has advocated the use of intravenous hypertonic saline injections (120 gr. of salt to the pint of water) on the theoretical grounds that by oversalting the blood diarrhœa would be arrested by osmotic attraction of fluid from the intestines into the blood-vessels and the circulation thus be effectively maintained. Many years experience in India has convinced me that hypertonic salines possess no such specific actions, repeated injections of these, as of other salines, being in many cases necessary to maintain the circulation.

Isotonic salines (90 gr. of salt to the pint of water) have been found to answer all physiological requirements for the replacement of the fluid lost in cholera and the maintenance of the circulation until the flux from the bowel ceases. They are used intravenously, subcutaneously, and rectally as circumstances require. Intravenously they are administered preferably in the form of alkaline isotonic salines, which were first introduced by Sellards. He had observed that in cholera very large doses of alkalies were required by mouth to render the urine alkaline, and concluded that alkalies administered intravenously in conjunction with isotonic salines would probably relieve suppression of urine after collapse, and thus prevent the onset of uræmia. In practice this has proved true. Alkaline salines should therefore be used as a routine measure in the treatment of collapse in cholera, 60 gr. of sodium bicarbonate being added to each pint of isotonic saline solution.

In totally collapsed patients 3–4 pints of saline may be required at once to restore the pulse at the wrist, the solution being run into the vein at the rate of 2 oz. per minute. Should collapse recur, as it frequently does, either because of the absorption of the fluid by the dehydrated tissues or by its leakage through the denuded intestinal mucous membrane into the gut, further injections must be given until the circulation is adequately maintained, ½–2 pints being administered slowly on each occasion as circumstances demand. Intramuscular injections of pituitary extract are of considerable value in combating collapse, in conjunction with intravenous saline injections. Where the pulse at the wrist is very feeble, showing that collapse is impending, subcutaneous injections of isotonic saline under the skin of the flank are often successful in avoiding it. Rectal injections of hyperalkaline saline—150 gr. of sodium bicarbonate to the pint of isotonic saline—should be administered slowly every 2–4 hours in cases where collapse has been overcome but suppression of urine still persists.

Vaccination, either by hypodermic injection of ordinary vaccines or by oral administration of Besredka's bilivaccine, conveys immunity lasting for several months. These vaccines are thus useful where there is continued exposure to infection in endemic areas. In my experience the mixture of essential oils mentioned above, taken three times a day in doses of a drachm, during epidemics afford almost absolute protection against the disease.

Special Articles.

TEACHING OF PSYCHIATRY TO MEDICAL STUDENTS.

BY W. S. DAWSON, M.D. OXF.,
ROCKEFELLER MEDICAL FELLOW.

A NEED for alteration in the teaching of psychiatry in British medical schools has long been apparent, and has now been commented upon by the Royal Commission in Lunacy. A revision of the present curriculum is all the more imperative on account of the mental hygiene movement which, already well established in the United States and elsewhere, is beginning to assume activity in this country. Moreover, it is likely that before long the medical profession will be called upon to deal more effectively than hitherto with the problem of mental disorders. The graduate who wishes to specialise is already provided for in several comprehensive courses of instruction, while the general practitioner embarks upon his work with an all-too-narrow outlook resulting from the scanty attention paid to psychiatry in his student years. Under the present régime not a few medical students carry away with them an unduly restricted and pessimistic impression of mental disorders derived from their experience of demonstrations at mental hospitals, and from instruction which is often limited to descriptions of neurotic and psychotic types, with scanty attention to the underlying principles of investigation and treatment. Not until this attitude is corrected and broadened by a revision of the present methods of teaching will the general practitioner be prepared to play that adequate part in the early treatment of mental disorder which modern knowledge is rendering possible and which the general public is beginning to demand. The matter has been receiving attention in the United States, where the teaching of psychiatry in some medical schools is free from the defects of our system and has certain features which might be adopted with advantage.

Teaching of Psychiatry in America.

Some years ago the American Medical Association made a survey of medical schools in the United States, and categories were drawn up according to the standard of teaching. More recently an inquiry was made concerning instruction in psychiatry, and, while it was found that even in the "A" class schools there was a great variation in the importance attached to this subject, yet it was the general opinion that 60 hours, divided equally between didactic and clinical work, was the minimum time which should be set apart. Several schools in which psychiatry was taught as part of the neurology course reported that their schedules were in process of revision, so that the former might receive the attention demanded by modern requirements. The following are the courses in psychiatry required by certain universities.

1. *Chicago.*

Two year pre-medical courses in psychology are optional, but are strongly urged (48 to 96 hours lectures and practical work).

Clinical Psychiatry.—Demonstration and conference courses at the Psychopathic Hospital (a hospital for early mental cases run in connexion both with the university and a general hospital), 24 hours. Clinical and conference course of 24 hours at a public mental hospital.

2. *Colorado.*

Third Year.—Lectures on the fundamental laws of psychology as applied to the relation of physician and patient, and to diseased states; psycho-analysis.

Fourth Year.—Clinical instruction in psychiatry and neurology, 42 hours. The class is divided into small sections, each spending one and a half hours daily for three and a half weeks. Lectures in neurology and psychiatry, 66 hours. In the lectures in psychiatry special attention is paid to the neuroses and to the principles of psychotherapy.

3. *Columbia, New York.*

Second Year.—Fifteen lectures and demonstrations in psychopathology. 1. Introductory: Mind and medicine. 2. Structural basis for mind (mind and body). 3. General concepts of intellect and emotion. 4. The "ego instinct" group. 5. The "sex instinct" group. 6. The "herd instinct" group. 7. Cultural modifications of instinctive behaviour. 8 and 9. Mental mechanisms. 10. Abnormal types of mental adaptation; Psychoneurosis. 11. Psychosis. 12. Anomalies of mental development; crime, drug, and alcohol addiction. 13. Psychopathology of general illness. 14. Foundations for social psychiatry. 15. Foundations for mental hygiene.

Third Year.—Psychiatry, 15 lectures.

Fourth Year.—Thirty clinical lectures.

A total of 60 hours is required from all students. Certain additional courses are available, but are not obligatory.

4. *Harvard.*

First Year.—Medical psychology, 10 lectures. The topics include: Environment; emotional reactions; modification of experience; rôle played in these reactions by the various systems; ability to receive, elaborate, store, and reactivate impressions; variations in constitutional endowment; special lines of weakness; importance of personal factors in medicine in general and especially in relation to nervous and mental disorders.

Third Year.—Sixteen clinical lectures at the Boston Psychopathic Hospital. Examples of all the more important

varieties of mental disorder; special emphasis on mild and incipient cases which are frequently treated by the general practitioner. More attention is given to the dynamic analysis and practical problems of the individual case than to questions of formal classification. Examples of nervous and mental diseases of childhood are presented. Each student is given an opportunity to study individual cases. Instruction is also carried on in 12 periods of two and a half hours each, in which small groups of students examine and discuss cases under the supervision of members of the staff.

5. *Johns Hopkins Hospital (Phipps Institute).*

The following courses are obligatory.

First Year.—Personality study as a concrete basis on which to become familiar with the data and methods of descriptive and dynamic psychobiology. Ten hours of class discussion followed by group discussion in which personal problems and experiences are reviewed.

This course enables the student to gain some insight into the working of his own mental processes, so that later he may handle patients with greater understanding of the determinants of conduct, emotional factors, intellectual assets and deficits, and so forth. The student is encouraged to think out his own problems rather than to accept some definite school of psychological thought. In many respects this course is more of a mental exercise than a set form of instruction.

Second Year.—Course familiarising the student with the methods of examination of cases with well-defined problems and reaction types. Emphasis is laid on: Methods of taking the life-history; study of assets and determining factors; intelligence tests; mental status; principles of getting at dynamic determining factors of the patient's life; study of orientative activity, associative processes and resources, affective assets, and habit formations.

This course takes 20 hours of group work. The success with which the student approaches this stage of his work will have been determined largely by the thoroughness with which he entered into the course of the preceding year.

Third Year.—Examination and discussion of cases. Review of fundamental psychopathological reaction types. In this course stress is laid on the study of types and problems, on the observation of symptoms and signs in an orderly manner, and on the recognition of outstanding problems of adjustment. Somatic therapy, the principles of treatment by rest, graded re-education and other measures also receive attention. There is a recapitulation and study of psychogenic and constitutional problems. The course is completed in eight periods of two hours each in groups of five students.

Fourth Year.—Eleven clinical demonstrations of psychiatric cases, groups, and topics. Individual study and report of at least six cases (out-patient or ward) during the fourth year.

All the courses of instruction at the Johns Hopkins total not less than 65 hours, spread over the four years of clinical study. The aims of this teaching have been expressed by Dr. Adolf Meyer, Professor of Psychiatry at Johns Hopkins, as follows:—

"The most fundamental departure from current tradition is the emphasis not on the question whether the patient presents one or other of a set of diseases, but rather on the question how many facts and conditions enter into the state of the patient, what reaction complexes are recognisable as relative entities, and what psychopathologic, cerebral, general, somatic, endocrine, toxic, and infectious components. Let us get away from the dominant notion of classification of each patient as having just one exclusive disease."—Progress in Teaching Psychiatry, *Jour. Amer. Med. Assoc.*, vol. lxix., 1917.

The courses at the Johns Hopkins are the most comprehensive and liberal of all, and have served as an example to other medical schools in the United States, in many of which Hopkins graduates hold teaching positions. With the growth of scientific aids to medical diagnosis, and with the development of laboratory methods, there is an increasing danger of overlooking the personalities of the patients and the psychological factors in the clinical picture. How often does a diagnosis of "functional" after exhaustive physical examinations spell the cessation of efforts in further investigation and treatment on psychological lines! Some time ago Dr. G. E. Vincent, of the Rockefeller Foundation, spoke on this topic:

"It has been asserted with some reason that in its preoccupation with the diseases of the body scientific medicine has too much neglected the psychic and social factors. The rapid spread of the cults which invoke various forms of mental suggestion is probably due in some measure to the failure of modern medicine to include in its scope the relations of mental and physical states, to study these in a scientific spirit, and to utilise the healing power of rationally controlled suggestion. Recent progress in psychiatry, war-time experiences with disorders of the mind, the rise of mental hygiene, and the increased attention being given to these subjects in medical schools and at professional meetings, are evidence that the mental aspect of disease is being recognised more fully."

The Ends in View.

The leading medical schools in the United States aim at training the future medical practitioner to deal with the "functionals," the neurotics, and the psychotics which form no inconsiderable part of his practice with some understanding of scientific principles, instead of leaving him to learn by sad experience that many of his problems are psychobiological rather than physical.

Certain features in the schedules given above call for special comment. In the first place the student is introduced to psychology in his preclinical or early in his clinical years, so that he comes to the study of psychiatry with a certain amount of preparation and with some understanding of the dynamic factors which underlie normal and abnormal conduct; secondly, he is prepared to appreciate psychological factors in other departments of his clinical work; thirdly, clinical instruction in psychological medicine is wider and more intensive than is required by our examining bodies, and assumes an importance equal to that of other branches of medicine instead of remaining an unconsidered trifle. The actual handling and reporting of cases gives the student an understanding of psychopathological problems and of methods of treatment which lectures and demonstrations alone could scarcely do.

If, as is hoped and as the Royal Commission has urged, facilities for early treatment of mental disorders are multiplied, it may be expected that out- and in-patient clinics will work in close association with the general (teaching) hospitals. There should be no difficulty in finding adequate material for students even under existing conditions. Additions to an already overburdened curriculum are hardly to be contemplated. But modification of present teaching in psychiatry should receive serious attention.

Lectures in medical psychology have already been instituted in one or two British universities and should be available for students in all medical schools after the second professional examination has been passed. Quite general topics might be selected, provided that their bearing on psychiatry is kept in mind. A course of six lectures might be given as follows: (1) Relation of mind and body; (2) dynamic concept of psychology; (3) emotion and instinct; (4) mental mechanisms; (5) study of personality; (6) the individual and society.

In the teaching of clinical psychiatry greater attention might be paid to the actual handling of cases. The demonstration of severe and chronic types of mental disorder found in mental hospitals and of the more pronounced forms of congenital mental defect is of at least questionable benefit for the general practitioner, provided that he is taught to recognise suicidal risks and other dangerous anti-social tendencies. If no addition to the present curriculum is feasible, at least four of the 10 or 12 demonstrations which are usually given in mental hospitals might usefully be replaced by attendance and instruction in the psychiatric out-patient department of a teaching hospital. The value of investigating and reporting on cases, as is done in internal medicine, cannot be overestimated as a means of familiarising the student with the problems which have to be faced in psychiatry. It will be noted that this is made a special feature of the teaching at Harvard and Johns Hopkins. It is difficult in the dozen or so lectures which are usually given to cover all the ground which is desirable. A lecture devoted to the principles of case-taking and the evaluation and interpretation of symptoms would be of the greatest benefit. Other topics, such as the handling of neurotic and psychotic cases in general practice, the aims of mental hygiene, and the psychopathology of childhood, would be of more practical use

to the general practitioner than instruction about idiocy and dementia. Above all, it is desirable to inculcate a wider appreciation of psychiatry as not being limited to incurable "insanity." Questions on psychiatry should find a regular place in the papers, and cases should be presented for commentary in the clinical part of the final examinations.

It may be anticipated that if the student is given greater encouragement to regard psychiatry as a subject which is as important as other branches of medicine, he will not only reap the benefit in practice by feeling better able to cope with the psychiatric problems which come before him, but also that he will be in a position to further the aims of mental hygiene. Psychiatry has not yet said the last word on the question of the difficult and "nervous" child, the juvenile delinquent, and many other varieties of mal-adjusted personality. In the developments which have already taken place in the United States and which are being attempted in this country the general practitioner must be a sympathetic agent.

MEDICINE AND THE LAW.

Forceps Left in the Body after Operation: "Negligence but not Gross Negligence."

AT an inquest held last week upon a woman, aged 47, who died in St. George's Hospital, the verdict recorded by the coroner (Mr. Ingleby Oddie) was that "death was due to peritonitis following an operation for the removal of a pair of artery forceps negligently left behind in September, 1923, during an operation for the removal of a cyst." The coroner added, "and I further say that the said negligence was not gross and culpable."

The history of the case appeared from the hospital notes of the date in question, which were produced by Dr. R. A. Burns, at present resident assistant surgeon at St. George's Hospital. The deceased had been admitted to hospital on Sept. 16th, 1923, for immediate operation. She recovered and was discharged a month later. On Sept. 15th of the present year an operation was performed and a pair of Littlewood's forceps were found in the pelvis. They were six inches long and were still held together by erosion though broken. The patient progressed favourably and there were hopes of her recovery, but on Sept. 17th she died. Dr. H. B. Weir, who made the post-mortem examination, said death was due to peritonitis following the operation for removal of a foreign body from the intestines; he said he had read of such cases but had never seen one.

The coroner's verdict, it will be observed, distinguishes between simple negligence and negligence which is gross and culpable. This distinction corresponds with the difference between the lesser degree of negligence which is necessary in a civil action for damages and the more serious degree of negligence which must be present to justify a criminal charge. As the deceased did not survive there can be no question of a civil action for damages for negligence; her right to claim damages died with her. Otherwise it would have been strange if a jury in the High Court or in a county court had not considered it negligent to leave a pair of forceps in a patient's body after operation. The legal duty not to do so is so plain as to admit no denial; as the lawyers say, *res ipsa loquitur*—the damage tells its own story. It might, of course, have been difficult for the plaintiff to fix the personal responsibility. Dr. Weir, in his evidence at the inquest, stated that at St. Thomas's Hospital it is the custom to make a sister responsible for looking after all the instruments of an operation; he added, "the surgeon, however, is responsible for everything." The hospital itself would not be legally liable in damages. "A hospital authority," said Lord Justice Kennedy in Hillyer *v.* Governors of St. Bartholomew's Hospital (1909), "does not make itself liable in damages if members of its staff, of whose competence there is no question, act negligently towards a patient in some matter of professional care or skill or neglect to use or use negligently in his treatment the apparatus or appliances which are at their disposal." But the individual physician or surgeon may be sued provided that the action is begun within the period prescribed by the Statutes of Limitations. It is perhaps worth noting that, if the deceased had survived and had sued for damages, the period of six years within which she would have had to begin her action would have dated from September, 1923, when the alleged negligence occurred, and not from the later date when the unfortunate consequences were discovered.

To turn back to the criminal aspect of the case, Mr. Ingleby Oddie's verdict is a refusal to set the criminal law in motion. A coroner's verdict of murder or manslaughter against a named person is technically sufficient to send that person for trial before a criminal court. In practice, however, the coroner's verdict is seldom relied upon for this purpose, but proceedings are initiated before magistrates in order to have the accused committed for trial in the ordinary way. Where, as in the present case, the coroner's verdict has the deliberate effect of exonerating all concerned from any charge of criminal negligence, it would be most unusual to take any further criminal proceedings before magistrates with a view to placing anyone upon his trial.

Destruction of Dog Suspected of Rabies.

A police-sergeant stationed at Balham was summoned on Sept. 23rd for ill-treating a dog by killing it in such a manner as to cause it unnecessary suffering. The dog, it seems, was brought to the police station under suspicion of suffering from rabies. The officer, believing the suspicion reasonably well founded, killed the dog with three blows of his truncheon. It was alleged that the animal's cries aroused the neighbours, and ultimately the Royal Society for Prevention of Cruelty to Animals prosecuted the sergeant. Section 61 of the Metropolitan Police Act of 1839 authorises a constable of the Metropolitan Police Force to destroy any dog or other animal "reasonably suspected to be in a rabid state." The prosecution said there might have been adequate reasons for destroying this dog, but there could be none for killing it in this particular way. The magistrate held that the sergeant had not intended to cause unnecessary suffering but had in fact done so; he should not have hit the dog at random with his truncheon. The case was dealt with by ordering the defendant to pay 5 guineas costs but no penalty.

Parliament has made other provisions for the disposal of unwanted dogs. The Metropolitan Streets Act of 1867 (Section 18) authorises a magistrate, if he has cognisance of a complaint that a dog has bitten or attempted to bite any person in the metropolis, to direct its destruction, "and any police constable may destroy the same accordingly." Stray dogs seized and detained by a police officer under the general powers of Section 3 of the Dogs Act of 1906 may, if unclaimed after seven days, be destroyed "in a manner to cause as little pain as possible," and a warm-hearted legislature added that no dog so seized should be given or sold for the purpose of vivisection.

Rabies is a disease of which, happily, the present inhabitants of this country know very little. Probably, however, they know enough to take no risks. If a dog, alleged to be mad, is seen running at large in a public place, prudence may dictate its immediate destruction by any means possible. But if a dog is chained up at a police station, the same precipitancy may not be necessary. In the recent proceedings, when the police-sergeant quoted the 1839 Act as his authority to destroy upon reasonable suspicion, the representative of the prosecuting Society submitted that that provision applied only to dogs in the public street, not to dogs tied up at a police station. The submission is probably wrong as a matter of law, and in any case sympathy cannot be withheld from the police officer who undertakes an unpleasant and

possibly dangerous duty. But the incident suggests various questions. Are adequate official instructions issued to the police for dealing with occasions of this kind? Is the possibility of veterinary examination and of using a painless killer borne in mind? And was any post-mortem or other investigation made to ascertain if this was in fact a case of rabies?

Dangerous Drugs Regulations: A Severe Sentence.

The prosecution recently undertaken under the new Dangerous Drugs Regulations, which specially prohibit a drug addict from obtaining morphia preparations through several practitioners without disclosing the fact, has ended in a severe sentence. Mr. Gill, the Westminster police-court magistrate, at a previous hearing, seemed willing to release the accused on condition of his entering a home. At the final hearing, however, on Sept. 15th, a detective-inspector gave evidence of the man's criminal record which made a considerable difference to the magisterial disposal of the case. It appeared that the defendant had been convicted in different names of both fraud and housebreaking and that, though it was true that (as he had stated) he was gassed during the war, he was sentenced to three years' penal servitude in January, 1923. Mr. Gill passed a sentence of four months' imprisonment. It is hardly to be supposed that a drug addict who infringes the new Regulation will be so severely dealt with if his character is reasonably good.

NATIONAL HEALTH INSURANCE.

NEW ARRANGEMENTS FOR DENTAL BENEFIT.

SINCE July last a greatly increased number of insured persons have become entitled to dental benefit, the amount of money available for its provision exceeds £2,000,000 per annum, and a large majority of the approved societies and of the practising members of the dental profession are now concerned. During July a Dental Benefit Joint Committee, consisting of 14 members representative of approved societies and 14 of the dental profession, considered a new scale of fees and conditions of service, and early in August the report of this committee was approved by the Consultative Councils in England and Scotland.

It is understood that private contracts between patients and dentists for the payment of additional fees are only permissible under this agreement in exceptional conditions or where some form of treatment or appliance is desired not provided for in the scale, and the insured person is prepared to meet the additional charge. The committee recommended that the adoption of the new scale of dental charges should be conditional upon the institution of a service of regional dental officers charged with duties somewhat similar in character to those of regional medical officers, and the Ministry of Health and Scottish Board have undertaken to frame a scheme for such a service, the expenses to be defrayed out of the funds available for dental benefit. Under the schemes of dental benefit now in operation it is a condition that the whole of the cost of dental treatment shall be defrayed by the society, except that as regards provision of artificial teeth and repairs and remodelling of dentures a society may decide to pay a proportion of the cost, not being less than one-half. This provision was adopted on the advice of the Consultative Council with the object of encouraging conservative treatment. Apprehension having been expressed by certain societies that benefit under the new conditions may exhaust the available funds, the central health departments are considering the possibility of amending the scheme so as to permit a society in suitable circumstances to pay a proportion only of the cost of treatment, the principle of encouraging conservative treatment being maintained. The Dental Benefit Joint Committee will also prepare a model dental letter and formulate procedure for disciplinary action.

Agreed Scale of Dental Charges.

The following is the scale of dental charges for members of approved societies, which has been approved by the Dental Benefit Joint Committee, and is to operate from Oct. 1st, 1926, to July 6th, 1930:—

	£	s.	d.
1. Scaling and treatment of the gums—per individual	0	7	6
2. Fillings—per filling	0	7	6
3. Root treatment—			
Six front teeth, upper or lower—per tooth	0	5	0
Remainder, upper or lower—per tooth	0	7	6
4. Crowns, gold or other—per crown	1	11	6
Where root treatment is necessary, this may be charged for at the rates shown in (3) above.			
5. (*a*) Extractions—			
With or without local anæsthetic—per tooth	0	2	6
Maximum fee for upper or lower	0	15	0
Maximum fee for upper and lower	1	5	0
(*b*) General anæsthetics: (i) Administration fee—			
Upper *or* lower	0	7	6
Upper *and* lower	0	10	0
Where nitrous oxide or similar anæsthetic (simple administration) is used, only one administration fee to be charged to each patient. Maximum fee for extractions, including simple administration of general anæsthetic—			
Upper *or* lower	1	2	6
Upper *and* lower	1	15	0
(ii) Under prolonged anæsthesia. Where not less than 12 teeth are extracted at one operation under prolonged anæsthesia, excluding the simple administration of nitrous oxide or similar anæsthetic—			
Dentist's fee (including all extractions)	1	5	0
Anæsthetist's fee	*1	1	0
* Or such lower sum as the anæsthetist is ordinarily prepared to accept.			
6. Dentures—			
For first two teeth on a denture	1	0	0
For each additional tooth	0	5	6
Fee for a full or nearly full (ten teeth or more) upper or lower denture	3	0	0
Fee for full or nearly full (ten teeth or more per denture) upper and lower dentures	6	0	0
Where the fee for full or nearly full denture applies to the single denture, no charges under items (1), (2), or (3) above to arise in respect of the jaw concerned. Where the fee for full or nearly full dentures applies to the double dentures, no charges under items (1), (2), or (3) above to arise.			
7. Repairs, additions, and emergency treatment—			
Repairs and emergency treatment up to 10*s.* without previous submission of estimate—account to be rendered to the society on the society's recognised dental letter.			
Minimum fee for repairs and/or additions	0	7	6
Maximum fee for repairs and/or additions	1	10	0
8. Remakes—			
Fees to be calculated at two-thirds or, within 12 months, at one-half of the scale, with necessary additional teeth at 5*s.* per tooth.			
Maximum fee, including additional teeth, per denture	2	10	0
9. Examination and report—			
Where patient does not return for treatment	0	2	6

Conditions and Specification of Materials.

An appendix to the scale sets out the conditions and specification of materials approved by the committee, and to come into force over the same period. The dentist shall apply to each case he undertakes the degree of skill and attention necessary, irrespectively of whether the patient comes to him under the terms of this agreement or as a private patient. The agreed scale is based upon the understanding that the dentist shall not be required to accept instalments or to incur the risk of bad debts, and may decline to commence or proceed with the work until he has received the proportion of the cost payable by the member. Any society which does not undertake liability for the full cost of dentures shall make this position clear to its members by an appropriate notice upon its dental letter. Other conditions binding on the dentist are these:—

Bands, wires, and fastenings must be of gold without extra charge.

After multiple extractions impressions for a permanent denture are not to be taken, except with the consent in writing of the approved society, within a period of three months from the date of the final extraction, but when it is necessary to fit dentures before the mouth is ready for permanent work, and the society approves this course, these must be of a permanent character and charged for at scale fees. These and all other new dentures are, if necessary, within 12 months to be remodelled or remade at one-half the original fee. It is understood that any necessary adjustment of the dentures within a reasonable

time after completion will be made by the dentist without additional charge.

The term " root treatment " is understood to mean either of the following: (1) The devitalisation of the pulp of a tooth and the subsequent removal of the pulp followed by the necessary treatment and filling of each root of the tooth. (2) The treatment of septic root canals and subsequent filling of each root. It does not include any dressing or treatment of the pulp of a conservative nature.

The anæsthetist's fee includes the cost of the anæsthetic as well as the cost of its administration. The choice of an anæsthetist will rest with the dentist performing the extractions. The anæsthetist must in all cases of prolonged anæsthesia be either a medical practitioner or a dentist (other than the dentist performing the extractions) skilled in the administration of a suitable general anæsthetic and included in a list to be approved by the Dental Benefit Joint Committee.

A dentist will be required to accept a dental letter only if it is produced to him within 21 days of the date of its issue and within six weeks of the commencement of treatment. He will be entitled to be paid, for such treatment as is then completed, at the original rates agreed upon between him and the patient. For the remainder of the treatment he will be entitled to the scale fees only. If a dental letter is produced either more than 21 days after the date of its issue, or more than six weeks after the commencement of treatment, the dentist will be entitled, if he so desires, to be paid for the whole of the treatment at the fees originally agreed upon. In order to avoid subsequent difficulties, the dentist before arranging on the occasion of a patient's first visit to charge on the basis of his private fees, should endeavour to satisfy himself as to whether the patient is or is not an insured person.

If a dentist is unable for any reason to complete the treatment authorised in respect of any insured person, he should notify the society concerned of the amount of treatment completed, of any payment already made by the insured person, and of the reasons for his inability to complete the remainder of the treatment.

If any doubt arises as to the correctness of interpretation of the scale of dental charges, the matter should be referred to the Secretary of the Dental Benefit Joint Committee, Ministry of Health, Whitehall, London, S.W. 1.

In the case of unforeseen conditions or unforeseen developments arising during treatment after diagnosis and acceptance of the estimate, the dentist may submit an additional estimate.

When any estimate has been submitted to an approved society and the society has questioned it, there shall be provision for an appeal by either party to a professional referee or committee to be recognised by the Dental Benefit Joint Committee.

The specification of materials to be used in work for members of approved societies provides that filling material is to be of first-grade quality manufactured by the best-known manufacturers and suitable for each individual cavity. In prosthetic work it is laid down:—

In vulcanite work, if pin teeth are used, all pins to be of (*a*) platinum, (*b*) nickel gold-cased, or cased with other precious metal, or (*c*) nickel alloy gold-cased, or cased with other precious metal, such as are made by the best-known manufacturers. Pins, gold or platinum, sheathed (i.e., anchored) within the porcelain, are permissible. If diatorics are used for anterior teeth, they are only to be used in cases where artificial gum is necessary and the upper anterior teeth must be wired in. All vulcanite partial cases must be sufficiently rigid. Metal strengtheners must be compatible with vulcanite and not liable to corrode in the mouth. Where gold has to be used for dentures by special estimate, it must not be less than 16 carat and must be of adequate strength. Bands and wires to be of not less than 16-carat gold, and bands to be not less than 7 gauge.

CALEDONIAN MEDICAL SOCIETY.—The annual meeting of this society was held at Storrs Hall Hotel, Windermere, on Sept. 24th. Dr. W. E. Henderson, the President, M.O.H. for Westmorland, delivered an address on the Historical and Literary Associations of Westmorland to a large audience. Sir Robert Jones, of Liverpool, and Sir Samuel Scott, High Sheriff of Westmorland, were elected honorary members, the annual dinner being held in the evening. The 1927 meeting is to take place at Dundee under the presidency of Dr. Angus MacGillivray, while in 1928 the society will celebrate its jubilee at Edinburgh under the joint presidency of its founders, Dr. S. Rutherford Macphail and Dr. W. A. Macnaughton.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Courses for Health Visitors.

LAST year the Scottish Board of Health arranged some four courses of lectures, demonstrations, and special visits for the health visitors of Scotland. A course was conducted in each of the four large cities. The educational value of post-graduate training is much higher than that of primary courses, since, to use a term less common than it used to be in psychology, the post-graduate's apperception masses are greater and better organised when, through experience, the weak points in his or her knowledge have been discovered. The functions of the health visitor are so novel and have developed at such a pace within the last ten years that most of those appointed in the earlier stages of the child welfare movement welcome the opportunity of seeing the great new developments at the city centres, and last year local authorities gave the movement their cordial support. The attendance was considerable, but it was felt that four such courses were rather more than the circumstances justified, and the Board has now decided that requirements will be met by courses held in the autumn and spring at either Aberdeen, Dundee, Edinburgh, or Glasgow. Local authorities may pay to their health visitors the fee for the course, travelling expenses (third class), and subsistence not exceeding £7 for the period. This expenditure ranks against the maternity and child welfare grant, or, in the case of whole-time tuberculosis nurses, against the tuberculosis maintenance grant. Since in Scotland the local education authority is an ad hoc authority, these two grants cannot apply to the school nurses, but the Board is " prepared to approve the attendance of school nurses at such refresher courses as part of the Education Authority's scheme for school health administration," and in this way the whole ground is covered.

It may be added that the Scottish National Association for Health Visitors, Women Sanitary Inspectors, and School Nurses is a thriving body. At its annual meeting some special subject—for example, ultra-violet light or venereal diseases—is discussed by a group of experts, and the Association is entertained every year by some local authority. In this way both the health interest and the administrative interest are kept in touch.

Nursing in Scottish Health Administration.

To a booklet issued by the Alexandra Memorial Fund Sir John Gilmour, Secretary of State for Scotland, contributes an article on the Place of Nursing in Scottish Health Administration. He states that for health visiting in maternity service, child welfare, tuberculosis, school nursing, and combinations of these, the Scottish local authorities (town and county) employ about 430 whole-time trained health visitors. There are also about 400 part-time official health visitors, or part and whole-time school nurses. He emphasises strongly the need for special social training along the lines followed at the Edinburgh University School of Social Study and Training. Courses on similar lines are being organised in Glasgow. It is now fully recognised by medical officers and local authorities alike that a nurse's training, indispensable as it is, is somewhat too restricted for the full development of a health visitor's work. In the cities, of course, there is always a preference for whole-time officers, but in the counties the large federations of county associations are coming into greater favour.

Women Citizens and Health Work.

The Edinburgh Women Citizens Association is one of the most active educational bodies in Scotland. For the coming winter some 80 lectures have been arranged, as well as visits to civic institutions and industries. Some of the lectures are public, others are given at special study circles and are paid for by fee. Such subjects as mental deficiency and maternal

morbidity are considered by study circles and general public meetings are devoted to discussions on juvenile delinquency, the milk-supply, the hospital patient, and like topics. The public meetings are usually very well attended and the study circles are said to be well maintained. Certainly the efforts of the women to educate themselves in the social aspects of medicine are receiving every encouragement from specialists, both clinical and administrative.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Condition of County Hospitals.

Dr. Brendan MacCarthy, one of the medical inspectors of the Department of Local Government and Public Health, has recently made a tour of inspection of the county hospitals of some of the counties of Leinster and Connaught, and has written a devastating report of the conditions of the hospitals in counties Longford, Leitrim, and Roscommon. In the Longford hospital he found the instruments rusty, the glasses broken, the water-supply and sanitary arrangements bad, medical stores in disorder, clothes caked with dirt, beds unmade, and floors blue-moulded. "It would be difficult," he says, "to exaggerate the conditions of disorder and neglect which were to be seen everywhere. . . . The conditions of the institution threatened the lives of the patients who came in for treatment." In the district hospital at Carrick-on-Shannon, co. Leitrim, he found no disinfecting apparatus, no provision for coping with fire, a primitive laundry with no heat for drying, and only one bath, that being on the top floor. In Roscommon surgical hospital "the cleanliness was bad," the cooking arrangements were poor, hot water was not obtainable, and there was no disinfecting apparatus. The clothes came home from the wash dirty and torn. The conditions of these hospitals comes as a shock and a disappointment to those who had accepted the statements made by the Department of Public Health and Local Government that the county hospitals were organised to meet the normal requirements of a county in regard to hospital treatment, and were provided with all necessary scientific equipment. To make matters worse, in two of the counties reported on, the local authorities had been superseded by commissioners appointed by the Minister for Local Government and Public Health, and the responsibility for the scandalous state of the hospitals cannot, therefore, lie with the local authorities. Up to the present the system of administration by commissioners had commended itself to the public on grounds both of efficiency and economy, but these reports will give it a set-back.

Public Health Appointments in Cork.

The resignation is announced of Dr. Denis D. Donovan, who has been superintendent medical officer of health for the city of Cork for more than 40 years past. Dr. Donovan was not a whole-time medical officer of health, but a physician in busy practice, and there is now an opportunity to organise a system of health administration for the city under the charge of a whole-time medical officer. Cork is the second city in the Irish Free State, with a population of 78,468. Its death-rate last week was 21·9 per 1000 per annum. It is clear that such a city affords ample scope for the services of an expert sanitarian. Unfortunately, the commissioner administering the city takes another view, and he proposes to appoint a person to the combined office of medical officer of health and tuberculosis officer at a salary of £800 a year, rising to £1000. The salary is, of course, inadequate, and the proposal to combine public health and clinical duties is bad in principle.

The Medical Register.

The Executive Council issued a further order last week continuing the present system of medical registration for another month.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Infectious Diseases in Germany.

According to statistical records the number of deaths from puerperal fever has risen from 6935 in 1924 to 7005 cases in 1925. The incidence of hydrophobia shows a decrease from 48 to 20, the suspected cases having fallen from 2417 to 1160. Encephalitis lethargica has been diagnosed in 217 cases, against 156 last year; and trachoma in 2777, against 1809, the cause of the last-named increase being that agricultural labourers coming from the East have conveyed the infection to Germany. Infantile paralysis had decreased from 507 to 387 cases, the majority occurring in September, the smallest number in January. It would seem, however, that this disease again shows a tendency to spread; cases are reported from many places, and some schools are being closed.

The Cinema and the Child.

The influence of the cinema on the child described in the report of Dr. Newsholme, quoted in your issue of August 21st, has also been observed in Germany. In some cases a visit to a film featuring crime has been held to have instigated the child to wrong-doing. According to the present law in Germany, children under 16 years of age are not admitted to cinemas. Exceptions are granted only for selected performances—for example, humorous episodes or films of historical character, where neither cruelty nor battle, nor dominance and submission are represented. When the film control office has granted permission to admit children to any performances, the programme and advertisements must bear the words, "children admitted," otherwise entrance is refused.

QUEEN ALEXANDRA SANATORIUM FUND.

THIS Fund in its report for 1925–26, just issued, points out that for several years the policy of the Council had been to engage the whole of the rooms at a pension at Davos for the winter months, and to concentrate there all the patients helped by the Fund. This arrangement gave the patients the advantage of the society of a number of their own countrymen and women, while their supervision by the visiting physicians was easily arranged for. It was, in fact, the nearest approach possible to a British sanatorium on the old lines. While Davos was still only recovering from the depression caused by the war, an arrangement of this sort was welcomed by pension proprietors, who were assured of a full house. But with the return of prosperity, the terms the Fund could offer ceased to be attractive, and a new system had to be devised. In theory there were two possibilities, either to hire vacant premises and equip and staff them, a course full of financial and administrative difficulties, or to give up trying to keep the assisted patients together, and to allow them, within limits, to choose their own pension or sanatorium. As no premises were forthcoming, force of circumstances led to the adoption for 1925–26 of the simple £2 a week grant system. This amount was made up of the old allowance towards board and lodging of Frs.35 per week, with an additional Frs.15 per week for treatment expenses. The new scheme proved popular with the patients, as they were no longer known as "fund" or "institution" patients. While the advantage of unified supervision and control which concentration in one building would offer, was missing, there occurred no serious failure to carry out strictly the prescribed régime. Of the 26 patients, 9 were in sanatoriums, the remaining 17 in 7 other approved buildings. All except 1 remained in Davos till the end of April, when the grants terminated. Disease was arrested in 2 cases, much improved in 12, and improved in 12. Four cases were treated with tuberculin injections, 3 by artificial pneumothorax, 5 had light treatment. There was 1 case of tuberculous peritonitis and 1 of intercurrent appendicitis. The number of inquiries about the Fund and of applications increases each year, and shows that there is a real need of assistance in some such form. Many persons cannot afford to go to Davos without some help, and the Fund has been instrumental in bridging over the difference between possibility and impossibility in nearly all the cases which have come under its operations. The London address of the Fund is Mr. D. Vesey (hon. secretary to the Council), 97, Warwick-road, Earl's Court, London, S.W. 5, and the local secretary is Mr. C. Healy, Davos Platz, Switzerland.

Correspondence.

"Audi alteram partem."

REFORM IN MIDWIFERY.

To the Editor of THE LANCET.

SIR,—I have been greatly interested in Prof. G. W. Theobald's plea for reform in the teaching of midwifery for students of medicine, and as a general practitioner of an experience of over 2500 maternity cases in private practice, I am giving the result of my own experience during many years in the practice of midwifery. In the first 1500 consecutive cases I tabulated my clinical observations with the object of elucidating the cause of sex, and since then midwifery has been the subject of my choice.

I think I can fairly say that among the 2500 cases every conceivable difficulty in delivery has been presented to me. I have managed every case alone, and on only three occasions did I call in another practitioner to give the anæsthetic to help me to deliver. None of my mothers died as the result of parturition although a stillbirth occurred occasionally, due to other causes. Miscarriages and abortions I pass over. Strange to say, the very first case in my own practice, although a natural delivery of a living child which is alive now, the mother, a syphilitic, died six weeks after delivery of meningitis. I had three cases of Cæsarean section, mothers alive now; one case of diabetes mellitus, when the mother, aged 35, died from that disease, the child being alive; one case of macrocephalon, the fœtus being dead but the mother alive; and a few cases of placenta prævia, mothers doing well.

Without going into any details as regards my own experience, my object is to endorse Prof. Theobald's plea for a reform in the method of teaching students in midwifery. No teaching is of practical use unless the student is required to spend the time necessary in practical midwifery to enable him to observe the cases as they occur under skilled guidance by a teacher in obstetrics. He will learn to observe the natural phenomena of labour, to be patient until action is required, and then to act with acquired professional skill. He will hesitate with both digital as well as instrumental interference, and probably save valuable lives. Nature in labour works aseptically and contamination by external interference must be prevented. Digital examination must be strictly aseptic and abdominal palpation is most valuable as a guide. I can strongly recommend to the student to either do practical midwifery under guidance at a maternity hospital or to assist a general practitioner in a large practice as I did. Theory alone is not sufficient; he gets plenty of instruction from his teachers. When I was a student I attended 250 maternity cases before I did any hospital work, and I feel glad that I did. Midwifery in the hands of insufficiently trained nurses should not be permitted and the expulsion of the placenta by them strictly forbidden. In skilled professional hands I advocate the judicial expulsion by manual pressure on the abdomen. As for binding the mother after delivery, I think that, generally speaking, it need not be done, but in cases of excessive abdominal distension before labour binding up is to be preferred. As to laceration of the perineum, I think the doctor can do a good deal to prevent it by bimanual pressure on the perineum at the time of delivery of the head. In all my cases I scarcely remember using the long forceps; I always use the short. I happen to be intimately acquainted with surgical instruments, their history, and their use, and this knowledge is the very reason why I hesitate to use them until expediency demands. In protracted labour I give morphine and atropine sulphate by the sublingual method direct. No hypodermic injections. Scopolamine I have not tried. Under proper circumstances a whiff of chloroform is much appreciated by the parturient woman, and it has the advantage of hastening labour. In an occipito-posterior presentation I do not think it good practice to turn it by means of the forceps into an anterior one. Although the man I worked under did this before my eyes, and showed me how to do it, I have never done it in any of my own cases. Asepsis during labour is most essential.

I had the honour of being taught by Lister himself, whose in-patient dresser I was, and I have always strictly observed antiseptic precautions. My finger-nails are cut very close, and my hands never touch the patient unless they are sterilised. Gloves I only use in suspicious cases. I do not agree with examining the patient per rectum in order to observe the progress of labour, but I give a strong aperient to clear the bowel and perhaps use a catheter before labour has advanced. If a douche is required I always use the biniodide of mercury and potassium 1 : 1000.

In all my cases I have only troubled the maternity institution with my three cases of Cæsarean section and one case of perforation. Speaking of these urgency operations, I think there should be cordial relations between the maternity institution and the general practitioner, and while this has been the case with all institutions, not maternity, with which I have been in contact, I could point out one or two where such cordiality has been completely absent.

I am, Sir, yours faithfully,

A. P. MURTZ, L.M.S.S.A., L.S.A.

Finsbury Park, N. Sept. 26th, 1926.

THE RIGHTING REFLEXES IN ENCEPHALITIS.

To the Editor of THE LANCET.

SIR,—The Cameron prize lectures, delivered by Prof. Rudolph Magnus and just published in your columns, are of the greatest interest and importance. Those of us who during the past four years have had an opportunity of hearing the addresses by Prof. Magnus on this subject have been impressed by the enormous amount of careful and brilliant work which forms the basis of his excellent addresses. The righting reflexes appear from clinical observations to be of considerable importance in man in whom the development of the erect posture has apparently caused certain slight alterations in these reflexes.

In confining himself to the subject in hand Prof. Magnus does not stress the importance of these reflexes either in the normal man or in the pathological states. The righting reflexes in man, in so far as they are shown in the neck muscles, can be very easily demonstrated if, on placing a hand anywhere at the level of the scapulæ, we give a person a push in a forward or backward direction. It is then seen that the head carries out a rapid movement in such a direction that the centre of gravity, if the push is a mild one, is instantly brought back to the normal. After this the shoulders, body, and head return relatively slowly to the normal posture and equilibrium. The same can be demonstrated for sudden lateral movement if the patient is standing on one foot. If we are testing the righting reflexes by causing a forward movement of the trunk, we stand behind the patient and can see the posterior muscles of the neck carry out a typical contraction which is apparently of reflex origin. In certain pathological states this reflex may be lost or impaired, and various degrees of loss or impairment may be observed in post-encephalitic manifestations. In the post-encephalitic the mental changes are in the majority of cases the most disabling, but the loss of the righting reflexes produces very great disability in that this loss appears to be one of the most important factors in the impairment of coördinated automatic movements such as walking, and particularly in any movement which demands sudden change of direction.

The work of Rademaker which Prof. Magnus quotes shows that the righting reflexes are lost if a section is made through the mid-brain of an animal behind the third nerves, and he regards the red nuclei as the centre of origin for the righting reflexes. Partial

destruction of centres which have been demonstrated to have important efferent paths which are afferent to the red nucleus or of the red nucleus itself have been shown to be constantly present in encephalitis lethargica. There is thus evidence that in encephalitis the loss of the righting reflexes is determined by impairment of the function of the red nucleus. Rademaker points out that the rubro-spinal tract is probably the efferent path from the red nuclei. During the last year and a half I have had an opportunity of examining something over 70 cases exhibiting the post-encephalitic state, and I have found that in all of them the righting reflexes are either impaired or absent.

Led by these considerations I have endeavoured by special exercises to restore the impaired righting reflexes in these cases, and was astonished to find that with such training the righting reflexes reappeared, and I think that I may go as far as to say that the post-encephalitic improved both subjectively and objectively in proportion to the degree of reappearance of his righting reflexes. The only explanation that has occurred to me is that alternative paths can by re-education be brought to function in relation to the red nucleus. The post-encephalitic forms the most interesting study of neck reflexes in man that I have encountered, but altered righting reflexes are also found in cases of labyrinthine disturbances and in other conditions. A cinematograph film of the exercises for retraining the righting reflexes in post-encephalitics has been prepared.

Finally I wish to make it clear that any observations that I have been able to make are entirely dependent upon the data which, as a result of his researches, Prof. Magnus has brought forward in his addresses, and I am indebted to Dr. P. C. P. Cloake and Dr. G. Eden, of the Nerve Hospital, Birmingham, for much valuable assistance in dealing with the neurological problems involved. I am, Sir, yours faithfully,

A. LOWNDES YATES.

Newhall-street, Birmingham, Sept. 26th, 1926.

STRETCHING THE INTUSSUSCIPIENS.

To the Editor of THE LANCET.

SIR,—In the encouraging article on intussusception by Mr. Hamilton Bailey in your last issue I note that he obtains help by Daw's method of stretching the intussuscipiens by forceps. There can be little doubt that reduction is often facilitated and resection avoided by some such method. In dealing with friable and œdematous tissues, however, the finger is a very safe and convenient instrument. By inserting the little finger between the entering and returning layers of the intussusceptum the surfaces can be separated and the œdematous fluid expressed out of the returning and ensheathing layers. I think if this method were used resection would be less often needed. I described and illustrated this method in the *British Journal of Surgery*, Vol. IX., p. 558.

I am, Sir, yours faithfully,

Harley-street, W., Sept. 26th, 1926. ZACHARY COPE.

"MICROBE HUNTERS."

A PUBLIC DENIAL.

To the Editor of THE LANCET.

SIR,—Our attention has been drawn to a book called "Microbe Hunters," recently published by Harcourt, Bruce and Company, New York, and alleged to have been written by one Paul de Kruif—a gentleman whose name is quite unknown to us. The work evidently aims at being a kind of popular history or rather romance regarding medical discovery, and mentions us among others. We should like an opportunity to say, for the information of your readers, that the author's statements about ourselves and our researches are almost entirely apocryphal; that they are not supported by reference to the original literature; that they are clearly derived almost only from his own imagination or from spurious prompting by others; and that his knowledge of the subjects with which we have been concerned is obviously incomplete.

We have been legally advised that some of his assertions regarding ourselves are libellous according to British laws, but in America we have no means of protection except a public denial of the truth of his allegations, and we therefore trust that you will allow us to publish such a denial, as emphatically as we may, in your columns.

Dr. Cuthbert Christy's signature does not appear on this letter as he is in Africa; before sailing, however, he left us the following statement: "With regard to Chapter IX. of Paul de Kruif's book, 'Microbe Hunters,' I beg to emphatically state that it contains statements which are totally erroneous, misleading, and some of them libellous. As an example I will quote paragraph 2, page 264, which reads: 'The third member (viz., myself) became disgusted with the ignorance and failures of his two colleagues and went off prospecting for rubber . . .' This paragraph is absolutely untrue and libellous. I never abandoned my colleagues, and, as a matter of fact, I did not get interested in rubber until 1906, which was three years after the labours of the First Sleeping Sickness Commission were completed."

We are, Sir, yours faithfully,

ALDO CASTELLANI. DAVID NABARRO.
GEORGE C. LOW. RONALD ROSS.

Sept. 27th, 1926.

HELIOTHERAPY IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—Dr. Chandler's letter in your issue of Sept. 11th (p. 574) advances a reasoned plea in favour of an extended trial of heliotherapy in pulmonary tuberculosis. In the light department of the Royal Free Hospital we have been giving ultra-violet light treatment to cases of active and quiescent pulmonary tuberculosis not only without harm, but with considerable benefit to the majority. These favourable results have not been secured without "buying our experience." For instance, in one case, a patient who had had a persistent backache following an injury, was freed from this pain by one strong erythema dose only to fall a victim to a serious flare up of an old (and unsuspected) pulmonary lesion.

As far as our present experience goes ultra-violet light can be safely given to cases of pulmonary tuberculosis if the following rules be observed.

1. That the initial dose should be one-quarter of the dose that will give the patient an erythema at 20 in., as tested by the "spot" method on the forearm.

2. That this quarter dose be secured by the appropriate increase of distance and not by a diminution of time.

3. That the skin first exposed be the legs and that a gradually increasing area of skin be added day by day. This being the only increase in dosage until the whole body is receiving this quarter erythema dose.

4. That subsequent increase in dosage be obtained by increasing the time of exposure with little or no diminution of the distance.

An accurate record of the weight and morning and evening temperature of these cases should, of course, be kept. In some way which I do not, as yet, understand, certain cases respond better to doses of ultra-violet light from a distance (and among these are cases of pulmonary tuberculosis) than to precisely the same dose, calculated on the inverse square law, when given close to the patient. I should be glad to know whether any of your readers have formed the same opinion from their clinical experience as regards this physical law not being strictly applicable to patients. I am, Sir, yours faithfully,

Park-crescent, W., Sept. 25th, 1926. C. B. HEALD.

PASTEURISATION OF MILK.

To the Editor of THE LANCET.

SIR,—I read Dr. Moore's letter with regret, as I had hoped we were in for a reaction against artificial interference with Nature. Dr. Moore asks for a specific case of the "deplorable results" of sterilised milk. Living in an out-port in China, my little girl was fed on an expensive brand of sterilised fresh milk supplied by a well-known firm; she developed scurvy and paralysis, which was cured by orange juice, raw meat juice sent from Shanghai, and milk supplied by a dirty Chinese from a more or less dirty goat. People to-day seem to forget that the marvellous human system is supplied with means to cope with a certain amount of poison. I have never lived in big cities, but in those places I have been we have never found it necessary to sterilise milk. As to the closing question "if we may cook most foods, why may we not cook one particular food?" surely Dr. Moore has not been reading his LANCET. One case reported there will suffice for many. Two Indian regiments suffered much from beri-beri; it was found that their vegetables were cooked too much; when the amount of cooking was reduced the nerve symptoms ceased. Is it not a recognised fact that the nearer we get to Nature the healthier we are?

I am, Sir, yours faithfully,

C. G. S. BARONSFEATHER.

Bournemouth, Sept. 25th, 1926.

Obituary.

WILLIAM EDWARD MARSHALL, *M.C.*, M.B., CH.B. EDIN., D.P.H.

NEWS has reached this country of the death at Khartoum on Sept. 24th of Major W. E. Marshall, who had only ten days previously taken up his new appointment of Principal Medical Officer, Sudan Defence Force. His death at a comparatively early age removes an officer of proved capacity in the many spheres in which his lot was cast and one who by his unfailing cheerfulness and resource had endeared himself to all with whom he came in contact.

Marshall was a native of Perth and graduated in medicine at the University of Edinburgh in 1902. He was appointed an assistant in the Bacteriological Department of the Lister Institute, London, in 1905, and in the three years during which he held this post he made a number of valuable contributions to bacteriological literature. In 1908 he entered the Royal Army Medical Corps, being attracted by the facilities that service might afford to one possessing his laboratory training combined with a very definite leaning towards the clinical side of medicine. From 1909 to the outbreak of war he was more or less continuously resident in the Sudan, and was largely occupied in the investigation of kala-azar in the region of the Blue Nile. During the war he served in Egypt and France, and in the Hedjaz, where he came into intimate personal contact with Colonel Lawrence and other notables of that picturesque campaign. He was again seconded for service in the Sudan in 1919, and in 1921 his special and sympathetic knowledge of local conditions, language, and people led to appointment as British Agent and Consul at Jeddah, where he successfully combined the duties of physician, administrator of quarantine, and political agent. He returned to this country in 1923, and until a few weeks ago was pathologist at Netley. It was apparent, however, that the spell of Arabia and Egypt clung to him in his post at home and it was with great eagerness that he looked forward to a further sojourn in the Sudan—a sojourn which has proved so brief.

Marshall was unmarried. He leaves behind him a pleasing memory of cheerful and unselfish devotion to duty and the ties of friendship.

Medical News.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A special demonstration on common injuries of the eye will be given by Mr. W. H. McMullen at the Royal Westminster Ophthalmic Hospital on Friday, Oct. 8th, at 5 P.M. This will be open to members of the medical profession without fee. A series of Fellowship lectures on emergencies in medicine and surgery will begin on Thursday, Oct. 14th; they will be given at 5 P.M. in the lecture-room of the Medical Society of London, 11, Chandos-street, W.; the full programme may be had on application. The Central London Throat, Nose and Ear Hospital will hold an intensive course in laryngology, rhinology, and otology from Oct. 4th to 23rd. The clinical course may be taken in conjunction with the operative, or separately, but early application is requested for the operative course as the entry is limited. (Fees, 5 guineas and 7 guineas.) From Oct. 18th to 30th there will be an all-day course in diseases of children in which the staffs of the Paddington Green Children's Hospital, the Victoria Hospital for Children, and the Children's Clinic will take part. Beginning on the same day there will be a two weeks' course in gynæcology at the Chelsea Hospital for Women. A two weeks' course in genito-urinary diseases will start on Oct. 18th at St. Peter's Hospital; there will be clinical work, including cystoscopies, every afternoon, as well as lectures. A series of eight clinical demonstrations of tropical diseases will be held twice weekly at 2 P.M., beginning on Oct. 5th, at the London School of Hygiene and Tropical Medicine. Copies of all syllabuses, of the General Course Programme, and of the *Post-Graduate Medical Journal* may be had from the Secretary at 1, Wimpole-street, London, W. 1.

HEALTH WEEK.—The committee appointed by the Royal Sanitary Institute has organised a Health Week from Oct. 3rd to 9th. More than 50 cities and towns are taking the opportunity to emphasise the importance of health problems and arouse the interest of their citizens in personal and social hygiene.

POST-GRADUATE COURSE AT ST. MARY'S HOSPITAL. During the week-end Oct. 2nd to 4th, a course for medical practitioners will be held at St. Mary's Hospital, Paddington, as follows:—Saturday: 10 A.M., Prof. C. A. Pannett, Acute Intestinal Obstruction; 10.45 A.M., Prof. F. H. Langmead on Mental Deficiency in Children; 12 noon, Mr. S. Maynard Smith, Errors in Surgical Diagnosis; 2.15 P.M., Mr. Zachary Cope, Common Fractures and Common Sense; 3.15 P.M., Mr. Aleck Bourne, the Scope of Cæsarean Section. Sunday: 11 A.M., Mr. R. M. Handfield-Jones, Common Surgical Problems (cases); 12 noon, Dr. C. M. Wilson, New Methods and Old Maladies (cases). Monday: 10 A.M., Mr. C. W. Gordon Bryan, Diagnosis of Some Disorders of Joints; 10.45, Dr. Reginald Miller, the Rheumatic Problem in Children; 12 noon, Sir William Willcox, Enteric Infections; 2.15 P.M., Mr. T. G. Stevens, Radium in Gynæcology; 3.15 P.M., Dr. A. F. Hurst, New Applications of Some Old Remedies. These meetings will be held in the library of the Medical School, and are open to all medical practitioners without fee.

LECTURES ON CHILD WELFARE AND CARE OF INFANTS.—A special refresher course of lectures on child welfare for health visitors, nurses, midwives, and others, will be held at the City Hall, Cardiff, on Saturdays, from Oct. 2nd. to 30th. The lecturers will be Dr. J. S. Fairbairn, Lady Barrett, Mr. W. Kittow, Dr. Eric Pritchard, Dr. J. C. Gilchrist, Dr. Ralph Picken, and Dr. Letitia Fairfield. The fee is 10*s.* 6*d.* for the whole course or 1*s.* 6*d.* for single lectures, and application for tickets should be made to the hon. secretary of the National League for Health, Maternity, and Child Welfare, 117, Piccadilly, London, W. 1, or to Dr. Picken, City Hall, Cardiff.—A course of post-graduate lectures on Infant Care, for health visitors, nurses, midwives, superintendents of welfare centres, and others will be given at the Infants Hospital, Vincent-square, Westminster, on Mondays, Oct. 4th to Dec. 6th, from 6.30 to 7.30 P.M., the lecturers being Dr. Margaret Lowenfeld, Dr. Donald Paterson, Dr. Eric Pritchard, Dr. W. E. Robinson, Dr. Margaret Emslie, Dr. A. F. Tredgold, and Dr. F. J. Poynton. Fees: whole course 7*s.* 6*d.*, single lectures 1*s.* Particulars may be had from the secretary, National Association for the Prevention of Infant Mortality, 117, Piccadilly.—A course of elementary lectures on Infant Care especially intended for creche nurses and probationers will be given by Dr. Prudence Gaffikin, at 117, Piccadilly, on Thursdays, Oct. 14th to Dec. 16th, at 7.30 P.M. Tickets (whole course, 10*s.* single lectures 1*s.*), may be had from the secretary of the association at the same address.

UNIVERSITY OF LONDON.—A course of eight lectures on the Special Senses will be given at University College by Dr. R. J. Lythgoe on Mondays and Wednesdays, beginning on Oct. 4th, at 5 P.M.—A course of ten lectures on Histology of Nerve Tissues and Paths of Conduction in the Central Nervous System will be given by Dr. C. Da Fano at King's College, on Thursdays, beginning on Oct. 7th, at 5 P.M.—A course of eight lectures on Biological Oxidation-Reduction will be given by Mr. R. K. Cannan at University College, on Fridays, beginning on Oct. 8th, at 5 P.M. Admission to these lectures is free, without ticket.

University of London: University College. — Dr. L Reuvid and Dr. E. R. P. Williams have been appointed demonstrators in anatomy, and Mr. L. E. Bayliss Sharpey Scholar in Physiology for the coming session.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—On Wednesday next, Oct. 6th, the inaugural sessional address to the Society will be delivered by Dr. James F. Tocher, B.Sc. Aberd., F.I.C., who will be presented on the occasion with the Pereira Medal, a silver medal provided and endowed out of the proceedings of a fund raised by subscription in 1853–54 as a memorial to Dr. Jonathan Pereira, M.D., F.R.S., a former professor of materia medica of the Pharmaceutical Society. The promoters of the fund resolved "that the medal should be awarded as a prize for researches or proficiency in materia medica," and the medal is presented annually for competition among the students in the advanced course in the Society's school. The medal was won this year by Mr. John George Jones.

MEDICAL DEFENCE UNION.—The annual general meeting was held on Sept. 23rd, when the President, Sir Herbert Waterhouse, moved the adoption of the annual report, which has already been referred to in THE LANCET (Sept. 25th, p. 663). In the course of his address he stated that the Council had decided to afford protection to members against whom actions were brought in consequence of the acts or omissions of locum tenents who were not members of a defence society, and had made a reciprocal arrangement with the London and Counties Medical Protection Society about such actions. The report of the Council and the financial statement for the year 1925 were adopted unanimously. Mr. W. T. Lydall, Mr. R. F. Jowers, and Dr. Seymour Taylor were unanimously re-elected members of the Council.

PEOPLE'S LEAGUE OF HEALTH.—The League has arranged a course of eight lectures on the Mind and What We Ought to Know About It, which will begin on Nov. 1st and continue on the following Mondays at 6 P.M. Among the lecturers will be Dr. E. Mapother, Dr. H. Crichton-Miller, Sir Maurice Craig, Sir Robert Armstrong-Jones, and Dr. A. F. Tredgold. A second course to be held on Nov. 3rd and the six Wednesdays after it, will deal with Diet: What We Should Eat and Why; among the lecturers will be Dr. Harry Campbell, Dr. Leonard Hill, Prof. Winifred Cullis, and Prof. W. E. Dixon. All the lectures will be held at 6 P.M. in the rooms of the Medical Society of London, 1, Chandos-street, W. 1. A fee of 10*s.* will be charged for the first course and a fee of 7*s.* 6*d.* for the second. For tickets and other particulars application should be made to Miss Olga Nethersole, at 12, Stratford-place, London, W. 1 (Tel.: Mayfair 0386).

OPENING OF THE MEDICAL SCHOOLS.—The following arrangements have been made in connexion with the opening of medical schools:—

Charing Cross Hospital.—Distribution of prizes by Field-Marshal Sir William Robertson, Wednesday, Oct. 6th, at 3.30 P.M., in the Out-patients' Hall of the Hospital. Annual dinner of past and present students on the same day at 7 for 7.30 P.M., at the Hotel Victoria, Northumberland-avenue.

University of Durham.—At the opening of the winter session of the University of Durham College of Medicine, Newcastle-upon-Tyne, an introductory address will be given by Dr. Charles Oliver Hawthorne, in the Examination Hall of the College, on Friday, Oct. 8th, at 4.30 P.M.

Guy's Hospital.—Distribution of prizes and an inaugural address by Dr. John Fawcett, Tuesday, Oct. 5th, at 3 P.M.

London Hospital.—Annual dinner of past and present students, Thursday, Oct. 21st, at the Trocadero Restaurant, at 7.30 for 8 P.M.

St. Mary's Hospital.—Annual dinner of past and present students, Monday, Oct. 4th, at 7 for 7.30 P.M., at the Connaught Rooms, Great Queen-street, W.C.

St. Thomas's Hospital.—Annual dinner of old students on Friday, Oct. 29th, at 7.30 P.M., at the Hotel Victoria, Northumberland-avenue.

ST. MARK'S HOSPITAL.—The festival dinner of the hospital will be held at the Mansion House on Tuesday, Oct. 26th, at 7 for 7.30 P.M.

NATIONAL INSTITUTE FOR THE DEAF.—Mr. C. M. R. Balbi, Associate Member of the Institute of Electrical Engineers, has been appointed honorary consultant to the Institute.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.—The office of the Association has removed from 20, Hanover-square, London, W. 1, to 19, Tavistock-square, London, W.C. 1 (Telephone: Museum 2577).

QUEEN MARY'S HOSPITAL FOR THE EAST-END.—A new block is to be erected that will give 24 additional beds, house the whole of the office staff, and provide a new board room and committee rooms. The cost will be between £30,000 and £35,000.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—Dr. Logan Turner, President of the Royal College of Surgeons of Edinburgh, will deliver an address on Some Aspects of Intracranial Infection of Nasal Origin at the opening of the winter session of the hospital on Friday, Oct. 15th, at 4 P.M.

NEUROLOGICAL CONFERENCE AT OSLO.—The Third Scandinavian Neurological Congress was held in Oslo on Sept. 17th and 18th under the presidency of Prof. Monrad-Krohn. The first day was devoted to reports and communications on neurosyphilis, and an interesting communication was read by Dr. Dahlström, who said that metalues was exceedingly rare amongst patients treated according to the principles of the late Prof. Boeck, of Oslo, an antimercurialist. On the second day Dr. Gundersen, of Oslo, raised the question of a possible close relation of epidemic encephalitis to epidemic parotitis. From epidemiological observations in Norway he showed the probability of a very close connexion between the two diseases. Prof. F. Henschen discussed the physiology of binocular vision, and in another communication pleaded the necessity of assuming the existence of an agraphic centre. Dr. Hansen related observations of a disease which he considered to be identical with Huntingdon's chorea and claimed that this disease was observed and described by a local practitioner in Norway long before Huntingdon. It was decided to hold the Fourth Neurological Congress at Helsingfors in 1929.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

PARLIAMENT reassembled on Monday, Sept. 27th, in order to renew the Regulations under the Emergency Powers Act in connexion with the stoppage in the coal industry.

HOUSE OF COMMONS.

MONDAY, SEPT. 27TH.

Hours of Work in Poor-law Hospitals.

On the motion for the adjournment of the House,

Miss SUSAN LAWRENCE said that many boards of guardians were becoming seriously indebted and were coming within the ambit of the Act passed last summer with the result that the Minister of Health could supersede them and administer relief through official nominees. It was therefore important to know on what principles the Minister of Health was administering relief. If, as appeared to be likely, more and more guardians came under the direct control of the Minister it was only reasonable to ask what were the principles upon which he acted. One of the first things which was done in the West Ham Union was to increase the hours of labour in the infirmary from 48 to 56 per week. The people concerned were sick nurses, sick attendants, and other officials of the hospital. Their union approached the nominee guardians and these admitted, according to the union's statement, that it was intended that consequent upon the increase in hours dismissals should take place. Eleven sick room attendants had already been dismissed, and it was anticipated in the locality that more were going. It would be bad enough if this were done in the London infirmaries, but it was much worse in connexion with the West Ham Infirmary for this reason—that in the case of the London infirmaries cancer and venereal disease cases were removed

to the Metropolitan Asylums Board hospitals where there was a 48-hours week. In adopting the 48-hours week the Metropolitan Asylums Board had no doubt borne in mind the notorious fact that there was no nursing so difficult, or which made so great a claim on the attention and physical strength of the nurses, as the nursing of the last stages of cancer cases or venereal disease cases. It was only by constant lifting of these patients that they escaped suffering in a very painful manner, and the first fruits of the model administration by the Minister of Health was just this—that the dying got less alleviation of their pain than formerly. These women and men were only human and they could not put as much work into a 12-hour shift as they did into a 8-hour shift. The nurses were on duty for two 12-hour shifts instead of three 8-hour shifts and with fewer numbers and longer hours it was impossible that the sick could be nursed as well as they were previously.

Mr. LAWSON said that in the coal-fields the situation was terrible. In the Chester-le-Street area, which he represented, gentlemen who were taking charge of affairs were more interested in giving proof of their ability to practise economy than in carrying out the principles of the Poor-law. The reason why the work of the Chester-le-Street guardians was taken over primarily was a dispute as to whether the young men were destitute or not. He thought that the Minister of Health might have done what the Scottish Board of Health did when there was a dispute and they could not get doctors to examine the cases. He might have sent doctors from headquarters in order to settle the question as to whether the men were destitute or not.

Mr. NEVILLE CHAMBERLAIN (Minister of Health) said that he must point out to Miss Lawrence and Mr. Lawson that under the Act passed this summer the present boards of guardians in West Ham and Chester-le-Street were not Special Commissioners, but boards of guardians for those unions—at any rate, for the time being—and the relations between them and the Ministry of Health were precisely the same as those between the Ministry and any other board of guardians. He had no more power over them than he had over any other board.

Mr. LYNN: You choose them.

Mr. NEVILLE CHAMBERLAIN: The hon. Member does not seem to remember the wording of the Act of Parliament. Parliament gave me the power to choose them, but it did not give me the power to dictate their policy. Continuing, the right hon. gentleman said that all he could do if he had a complaint of these guardians' action was to draw their attention to the complaint and to inquire what observations they had to make. That was precisely the course he had taken in the matter of the hours of the infirmary employees in West Ham. A deputation had been received at the Ministry of Health and the statements of the deputation were forwarded to the board of guardians for their observations, which had not yet been received. It was quite untrue to say that the dismissals of these servants were subject to his sanction. If the hon. Member had cases which he thought were cases of hardship or where guardians were not carrying out their duties he asked him to let him have particulars and he would forward them to the board and ask for their observations.

Dr. WATTS said he was continually struck by the objections to putting in more hours of labour on a healthy occupation such as that of mining. Mining was with one exception the healthiest occupation in the country. It was second only to that of the agricultural labourer. If hon. Members doubted that statement he would refer them to the statistics of the Registrar-General. There were very few diseases to which miners were specially prone and they were certainly not fatal diseases.

TUESDAY, SEPT. 28TH.

Boards of Guardians and Relief.

In reply to questions,

Mr. NEVILLE CHAMBERLAIN said that it was not the duty or the practice of boards of guardians to report changes in their administration or scale of relief, which they might use for their guidance, but he had been informed of reductions in scales made since May 1st in 42 instances. He knew of no case where a board of guardians ceased to grant any relief to dependants of those involved in the present coal stoppage, but six boards were reported to have decided that only indoor relief should be granted in these cases. Such a decision was within the discretion of the guardians so far as regarded applications considered by them, but nothing could interfere with the duty of a relieving officer to deal as might be required with any case of sudden or urgent necessity. He had no reason to suppose that boards of guardians were not fully discharging their duties in the matter.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, Oct. 5th.—5.30 P.M., ORTHOPÆDICS (Cases at 5 P.M.). Mr. Alan H. Todd, Mr. D. McCrae Aitken, and others. Mr. Paul Bernard Roth: Osteitis Deformans Affecting Chiefly the Skull and Pelvis. *Presidential Address:* Dr. W. T. Gordon Pugh: Orthopædics at a Country Children's Hospital (illustrated).
FRIDAY.—5.30 P.M., CLINICAL (Cases at 5 P.M.). Dr. L. S. T. Burrell, Dr. Bernard Myers, Dr. J. H. Sheldon, Dr. C. F. T. East, Dr. Douglas Firth, and Dr. J. L. Livingstone.—8.30 P.M., OPHTHALMOLOGY (Cases at 8 P.M.). *Presidential Address* by Mr. Ernest Clarke. *Epidiascope Demonstration:* Dr. Rayner Batten: Drawings of Macula Colobomata.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Oct. 4th, to SATURDAY, Oct. 9th.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross. Special demonstration on Common Injuries of the Eye, by Mr. W. H. McMullen, at 5 P.M. on Oct. 8th. This demonstration is open to medical men, without fee.—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road. Intensive Course in Clinical Laryngology, Rhinology, and Otology. Operative class also.—LONDON SCHOOL OF TROPICAL MEDICINE, Endsleigh-gardens, N.W. Tues., 2 P.M., Dr. G. C. Low, clinical demonstration. Thurs., 2 P.M., Dr. Manson-Bahr, clinical demonstration. Further information from the Secretary of the Fellowship of Medicine.
POST-GRADUATE HOSTEL, Imperial Hotel, Russell-square.
WEDNESDAY, Oct. 6th.—9 P.M., Sir James Dundas-Grant will open a discussion on Some Clinical Experiences.
THURSDAY.—9 P.M., Mr. Bedford Russell will open a discussion on Tonsillar Remains. All medical practitioners cordially invited.
LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Oct. 5th.—5 P.M., Dr. J. H. Stowers: Introductory Lecture.
THURSDAY.—5 P.M., Dr. J. M. H. MacLeod: Anatomy of the Skin.
HOSPITAL FOR SICK CHILDREN, Great Ormond-street.
THURSDAY, Oct. 7th.—4 P.M., Dr. Cockayne: Rickets as it is seen to-day.
NATIONAL HOSPITAL, Queen-square, Bloomsbury, W.C.
MONDAY, Oct. 4th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Adie: Disseminated Sclerosis.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Bernard Hart: The Psychoneuroses.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Martin: Hemiplegia.
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Symonds: The Pathogenesis and Treatment of Cerebral Vascular Disease.
MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSES.
TUESDAY, Oct. 5th.—4.15 P.M., Dr. F. Craven Moore: Early Diagnosis of Cancer of the Stomach.
FRIDAY.—4.15 P.M., Dr. C. Powell White: Modern Views as to the Cause of Cancer.
ST. MARGARET'S HOSPITAL FOR WOMEN, Acomb-street, Whitworth Park, Manchester.
WEDNESDAY, Oct. 6th.—4 P.M., Dr. N. C. Haring: The Treatment of Consumption in Young Girls.
ANCOATS HOSPITAL, POST-GRADUATE COURSE.
THURSDAY, Oct. 7th.—4.15 P.M., Mr. Harry Platt: Treatment of Common Injuries, Sprains and Minor Injuries of Joints, Muscles, and Tendons.
JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, ST. ANDREWS.
TUESDAY, Oct. 5th.—4 P.M., Dr. A. Maitland Ramsay: Introductory Address: The Muscle of the Heart, the Intestinal Tract, the Iris and the Ciliary Body—an Analogy and a Contrast. Discussion to be opened by Prof. Waterston.

Appointments.

BACK, MARJORIE, M.D. Lond., D.P.H., has been appointed Maternity Doctor under the Swansea Health Authority.
HOWELL, B. WHITCHURCH, F.R.C.S. Eng., Orthopædic Surgeon to St. Michael's Home for Crippled Children, Clacton-on-Sea.
YOUNG, W. A., M.D., Ch.B. Edin., D.P.H. Camb., Medical Officer of Health for Poplar.
Certifying Surgeons under the Factory and Workshop Acts: CHADWICK, J. W., L.R.C.P. Lond., M.R.C.S., Bollington District of the County of Chester; SUMMERHAYES, J. O., L.R.C.P. Lond., M.R.C.S., Newhaven District of the County of Sussex.
Royal Manchester Children's Hospital: STENT, Miss L., M.B., Ch.B., Assistant Medical Officer at Out-patients' Department; BACON, W. B., M.B., Ch.B. Manch., Resident Medical Officer at Pendlebury; SEED, N. F., M.B., Ch.B. Manch., Resident Surgical Officer at Pendlebury.
Salford Royal Hospital: ROANTREE, W. B., M.B., B.Ch., B.A.O. Dub., House Physician; SAVAGE, W. E., M.R.C.S., L.R.C.P., House Surgeon (attached to Orthopædic Department); WARBURTON, E. J., M.B., Ch.B. Manch., M.R.C.S., L.R.C.P., House Surgeon.

Vacancies.

For further information refer to the advertisement columns.

Barbados General Hospital.—Senior Res. S. £300.
Belgrave Hospital for Children, 1, Clapham-road, S.W.—H.S. and Asst. H.P. At rate of £100 each.
Bloomsbury Dispensary, 12, Bloomsbury-street, W.C.—Surg. 100 guineas.
Brighton, Royal Alexandra Hospital for Sick Children.—Hon. Consulting S., Hon. S., and Hon. Asst. S.
Cambridge, Addenbrooke's Hospital.—H.P. At rate of £130.
Cardiff City Mental Hospital, Whitchurch.—Sen. Asst. M.O. £550.
Croydon County Borough.—Asst. M.O. £600.
Croydon General Hospital.—Pathologist and Bacteriologist (Part-time.)
Derbyshire Royal Infirmary, Derby.—Two H.S.'s and Asst. H.S. and Cas. O. Each at rate of £150.
Edinburgh University, Physiology Dept.—Asst.
Gravesend Hospital, Kent.—Jun. H.S. £150.
Grosvenor Hospital for Women, Vincent-square, S.W.—Hon. Reg.
Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—H.P. and Cas. M.O. Each at rate of £100.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Asst. Res. M.O. At rate of £150. Also Pathologist, &c. £750. Also H.P. £50 for six months.
Leeds, St. James' Hospital, Beckett-street.—Chief M.O. £1000.
Liverpool City.—Medical Visitor under Lunacy Act, &c.
Manchester, Royal Infirmary, Roby-street.—Asst. M.O. At rate of £100.
Manchester, St. Mary's Hospital.—Two H.S.'s. Each at rate of £50.
Middlesex Hospital, W.—Phys. and Asst. Phys.
National Dental Hospital, Great Portland-street, W.—Hon. Anæsthetist.
North Middlesex Hospital, Edmonton, N.—Surgeon-Oculist. £1 1s. per hour.
Otago Hospital Board, Dunedin, N.Z.—Med. Supt. £1000.
Paddington Green Children's Hospital, W.—H.P. and H.S. Each £150.
Preston Royal Infirmary.—H.P. £190.
Queen's Hospital for Children, Hackney-road, E.—P. in charge of Skin Dept.
Reading, Royal Berkshire Hospital.—Third H.S. £150.
Royal Chest Hospital, City-road, E.C.—Res. M.O. At rate of £150. H.P. At rate of £100, and Anæsthetist. 10 guineas.
Royal Free Hospital, Gray's Inn-road, W.C.—Sen. Res. M.O. £150. Also Res. Asst. Pathologist. £150.
Royal National Orthopædic Hospital, 234, Great Portland-street, W. Surg. Reg. 100 guineas.
Salford City.—Bacteriologist. £600.
Salford Royal Hospital.—Radiologist. £300.
Stockton and Thornaby Hospital, Stockton-on-Tees.—Third Res. M.O. £150.
Swansea Hospital.—H.P. At rate of £150.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Cas. O. and Reg. £150.
Walsall General Hospital.—Sen. H.P. and Jun. H.S. At rate of £200 and £125 respectively.
West End Hospital for Nervous Diseases, Welbeck-street, W.—Hon. Reg.
Willesden General Hospital, Harlesden-road, N.W.—Res. H.S. and Non. Res. Cas. O. Each at rate of £100.
Windsor, King Edward VII. Hospital.—Hon. Asst. Anæsthetist to Ear, Nose, and Throat Dept.
Worksop, Victoria Hospital.—H.S. At rate of £170.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Birmingham, West (Warwickshire), and Newquay (Cornwall).

Births, Marriages, and Deaths.

BIRTHS.

FABER.—On Sept. 24th, at Chichele-road, Cricklewood, N.W., the wife of Dr. Hamilton S. Faber, of a son.
RODD.—On Sept. 25th, at Avenue-road, N.W., the wife of Captain A. Rodd, R.A.M.C., of a daughter.
SMITH.—On Sept. 25th, at Peckham-road, S.E., the wife of Dr. Kenneth V. Smith, of a son.

MARRIAGES.

ELLIOTT—ROBINSON.—On Sept. 23rd, at the Parish Church, Knotty Ash, S. E. Y. Elliott, M.R.C.S., L.R.C.P., to Irene, only daughter of A. Robinson and of the late Mrs. Robinson, Broadgreen, Liverpool.
HORNE—MOCLAIR.—On Sept. 8th, at St. Andrew's, Westland-row, Dublin, Andrew J. Horne, M.A., M.D., to Delia Moclair, M.B., D.P.H.
MOOR—STORRS.—On Sept. 21st, at Rochester Cathedral, Frewen Moor, *M.C.*, M.A., M.D., of Westgate-on-Sea, to Lucy Petronella Noel, younger daughter of the Very Rev. John Storrs, D.D., Dean of Rochester, and the late Hon. Mrs. Storrs.

DEATHS.

IEVERS.—On Sept. 22nd, suddenly, at St. Leonards, Eyre Ievers, M.D., C.M., late of Tonbridge, aged 78.
NICOLL.—On Sept. 25th, suddenly, at Braemar, Aberdeenshire, P. J. S. Nicoll, M.D., J.P., of Romford-road, Stratford, London.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE POST-GRADUATE HOSTEL.

SOME RECENT ADDRESSES.

THE evening meetings at the Post-Graduate Hostel (now housed at the Imperial Hotel, Russell-square, W.C.) have provided already an opportunity for the reading of interesting addresses upon clinical and upon broadly professional subjects, which have given rise to informal debates. These interchanges of views and experiences will become more useful as the facilities offered by the hostel are more widely recognised and the audiences grow larger. The activities of the organisation have been announced from time to time in THE LANCET, the subjects of debate and the openers being stated, with dates and times. All members of the medical profession are invited to be present and to participate in the discussion.

Among recent addresses, given as openings to debates, have been one from Prof. J. E. Frazer on the clinical bearings of certain embryological defaults—this is referred to elsewhere (see p. 718); one from Dr. Clark Trotter, the medical officer of health for the Borough of Islington, who dealt with the relation of the general practitioner to the health officer; and one from the Editor of THE LANCET upon signed contributions by medical men to the lay press.

The General Practitioner and the Health Officer.

Dr. Trotter reviewed the relations of the general practitioner to the health officer from a view which enabled him to give anecdotal illustrations of the particular principles which should regulate the relations. Dr. Trotter said that he began the study of medicine when unqualified assistants were in existence and, while admitting that in the general interests of the public and the profession they had to disappear, he was of opinion that with their disappearance there went also a large amount of that interest in the problems of midwifery and in the treatment of women and children which was at one time a feature of general practice; while the panel system had replaced club practice it had also altered a whole side of private practice. The following description of an old-time practitioner will be recognised as sufficiently accurate. "This man started from his medical school equipped with the up-to-date teaching of his time and possessed with one of the earliest clinical thermometers about a foot and a half long, which took about half an hour to register the temperature. His business instinct was strong; he kept up the counterfoils of his notification book, to make sure his fees tallied. Visiting a poor house with him when asked to see a case, one noted he lagged behind when leaving to collect his eighteenpence. With such fees this general practitioner acquired wealth, erecting a statue in his town to Queen Victoria, for no other object than to show his nephews that he might spend as he liked and not necessarily leave his money to them."

Dr. Trotter went on to mention his experiences with a general practitioner "who specialised in specialists," and and with others who were too ready to suppress clinical instincts and to substitute for considered diagnosis indiscriminate swabbing; and added a short review of the responsibilities incurred by both general practitioner and medical officer under the increasing array of enactments and orders in respect of public health and especially of housing. He commended the activities of welfare centres and child welfare schemes, but found that such schemes were not always regarded with favour by doctors who here failed to meet a public demand upon them which was reasonable if they wished to maintain the position of family physician. In detailing the duties of the health officer in respect of home sanitation and the incidence of disease, he urged that the health officer should give close attention to applications for housing accommodation, and to all questions of overcrowding, for here he should come into contact with the general practitioner of his area in a manner which must be mutually advantageous. A health officer cannot provide housing accommodation, he said, adding that, in the opinion of a High Court Judge, any family could keep poultry in a bedroom if they liked, as there was no law to prevent such an action. A stimulating address closed with the warning note that public health work is becoming now so specialised that health officers who have had no opportunities of studying the conditions of general practice should take every chance of doing so in their own areas.

Medical Communications to the Lay Press.

The Editor of THE LANCET began by pointing out that the apparently logical general conclusion that the public dissemination of medical information is good must be received with considerable reservations. It was necessary, he said, to consider the way in which the information is published as well as its character; where the public need for the information was clear the public ought to be able to get it from responsible

medical authorities, but this did not necessarily mean that a particular medical man should write a signed article. He held that it ought not to be beyond the ambition of responsible newspapers to provide these sound medical articles in editorial unsigned form, as is done, for instance, in the matter of political communications. Newspapers should be proud to rely upon their own prestige as a guarantee to their readers that only information was being given which was needed, and which was obtained from properly informed sources. At the same time it was admitted that, as the public laid particular stress upon the signature, the attitude of editors in trying to obtain the signed information was reasonable. The kind of article was then indicated briefly which clearly could be signed, both with public advantage and without professional inconvenience, and it was shown how this differed from the kind of article which would fall under the unfavourable notice of the General Medical Council or of the ethical committee of the British Medical Association. The articles which led to censure, and in the case of the General Medical Council to penal interference, were especially those whose contents wore an advertising appearance, this usually taking the form of giving advice on disputed pathological questions with an assumed superiority of knowledge. The speaker allowed and deplored the difficulty of exactly appraising communications as professional or unprofessional, because the situation led to public criticism of the General Medical Council for subjecting some members of the medical profession to penalties while leaving others alone. He wished accordingly that the General Medical Council would publish more details of some cases which had come under their penal jurisdiction, thus enabling the public to appreciate the reasons for any action taken, and doing away with a good deal of mischievous misunderstanding.

In a debate which followed, Mr. McAdam Eccles drew attention to the various kinds of signature employed by writers of articles, and referred especially to the printing of accompanying photographs and noticeable headlines.

Dr. Alfred Cox said the whole subject was a source of much anxiety to the British Medical Association, which was constantly charged with inconsistency. He thought it desirable that the public should have sound information about medical matters, but that the prestige of the profession was being lowered by the flood of signed communications to the press. He agreed that the appearance of medical articles in journals of good repute should be a guarantee of the author's standing without any signature, and that further information from the General Medical Council would be helpful.

Dr. P. H. Manson-Bahr, Dr. Clark Trotter, and Dr. Andrew Balfour also thought that sound medical information should be disseminated to the public, and the last, citing an experience in the United States, pointed out that medical news might be examined by a medical authority before it was published.

"MYOPLASTIC SUSPENSION."

UNDER this title Dr. E. M. Neville describes a method which his anatomical studies have led him to advocate for the support of displaced abdominal organs. His method is based upon the surgical principle that musculo-tendinous flaps cut in appropriate manner from neighbouring musculature are the most effective means for ensuring strength and adequate function in any suspension mechanism. Its application is manifold.

(1) *To the Misplaced Uterus.*—Instead of using the weak round ligament in the modified extraperitoneal Gilliam method a musculo-tendinous flap, cut from the distal and mesial portion of each half of the rectus abdominis muscle, is used for suspending the uterus, the defect in the abdominal wall being easily repaired.

(2) *To Severe Gastroptosis and Dilatation of the Stomach.*—A musculo-tendinous pedicle flap is cut from a selected part of each external abdominal oblique muscle, brought through the anterior abdominal wall, external to the rectus muscle and embedded, after reflection of suitable flaps of the serous coat, in the anterior wall of the stomach. The serous flaps are then wrapped and sewn round the intraperitoneal portions of the musculo-tendinous pedicle flaps. The stomach is thereby suspended in hammock-like fashion, retaining its freedom of mobility. The anterior abdominal wall is easily repaired.

(3) *To the Movable Kidney.*—A musculo-tendinous flap of the posterior part of the external abdominal oblique muscle is brought through the internal abdominal oblique muscle and the transversalis muscle and attached to the kidney which thereby is underslung. The latissimus dorsi muscle is utilised for covering over any defect by means of a suitable tendinous flap cut from it and sewn to the edge of the oblique muscle. The method may be combined with a suspension from the twelfth rib.

Dr. Neville goes on to suggest that myoplastic pedicle flaps may be used for other surgical purposes, such as the repair of a weak abdominal wall, especially after herniotomy and for recurrent and secondary ventral hernias. A myoplastic pedicle flap may be cut from the tensor fasciæ femoris muscle, brought across the inguinal region deep to Poupart's ligament, and implanted on the region selected for strengthening or repair. In certain cases this muscle may be used for suspending the uterus extraperitoneally.

LOOKING AT PICTURES.

IT was a happy idea of Messrs. Duckworth and Company to issue "The Picture Galleries Series," [1] being brief notes on the contents of the large art galleries of the country, written in each case by an official of the gallery and including a certain number of illustrations which are particularly explanatory of the text. To medical men, so many of whom delight in pictures and not a few of whom have some measure of artistic accomplishment, these publications may specially appeal because of the explanations which are given of the place which particular painters hold in the estimation of judges. The notes supply information on the influences which prevailed at certain dates in the schools of the different countries, so that we learn to perceive what one master derived from another and who made the great departures which have influenced pictorial art permanently. All the volumes, like the two under notice, should make the time spent in the galleries both more interesting and more informatory. The assistant keeper of the Tate Gallery is very frank in his criticism of certain later nineteenth century Academicians, but all his views will not be endorsed. He does not seem to understand that the motives for making a picture may be complex in his desire to keep the illustrator in his place.

A REGISTER FOR RECORDING THE PURCHASE OF DANGEROUS DRUGS.

A CONVENIENT register arranged for recording the purchases of Dangerous Drugs, by practitioners who do not do their own dispensing, has recently been issued by H. T. Woodrow and Co., 3, Cook-street, Liverpool. We may remind our readers that the keeping of such a register is now compulsory. The register is divided into four sections for entries of purchases containing morphine, cocaine, diamorphine, and medicinal opium respectively. Columns are provided for the date on which the supply was received, the name and address of the person, or firm whence it came, the amount of the drug, and the form in which it was obtained. A column headed "remarks" is to be used for correction or alteration of any entry, no obliteration or erasure being allowed. A summary of those clauses of the regulations now in force that relate to medical practitioners is included in the register, also a list of preparations exempted from the regulations.

GROWTHS IN PLANTS AND MAN.

WE have received from Dr. John Brown, in the course of his conduct of a campaign against cancer, a request for views on free clinics in relation to the disease and on, among other things, the biological range of cancer. The arguments for and against free clinics in this connexion were briefly stated in our columns a fortnight ago (see THE LANCET, Sept. 18th, p. 611). With regard to the biological range of cancer, Dr. Brown suggests that a book is needed as "An Introduction to the Study of the Etiology and Prevention of Tumours in Plants, Trees, and Animals, with special reference to the Racial Incidence of Cancer in Man." There is a huge medical and a huge botanical literature to consult already, and until, by study of these and experimentation, some more definite analogies between the action, say, of lichens and galls and the pathological manifestations of malignant disease are established, it is difficult to know what the terms of reference of the book which he asks for would be. Dr. Brown considers that it should be "complemental to human cancer by experts in the new sciences of modern biology," words which certainly open up a large field if we understand them rightly. It may be admitted that the cancer problem is linked with the problem of neoplastic growths in general, and it is common knowledge that many people have been studying kindred conditions in the animal and in the vegetable kingdom in the attempt to arrive at some deductions which should be of general use. Revelations of practical application have not yet been made, probably because there are not yet sufficient indications for a path of research along which scientific medicine and scientific botany can proceed in company.

ERRATUM.—In a note last week upon a new tracheotomy tube the original model should have been attributed to the late Mr. R. W. Parker, and not to Mr. Rushton Parker.

Addresses to Medical Students.*

SCIENCE OF CLINICAL MEDICINE.

Delivered at the Opening of the Winter Session of the Westminster Hospital on Oct. 1st, 1926,

BY SIR ARCHIBALD GARROD, K.C.M.G., D.M., F.R.C.P., F.R.S.,

REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD; CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

[Sir Archibald Garrod, having noted the complete revolution which the work of the bacteriologist and protozoologist has produced in the conception of the nature of disease during the last half century, pointed out that the demands of the medical student of the present day run along two separate paths: first, they must acquire a working knowledge of the science upon which medicine, using the word in its widest sense, rests; and secondly, they must study at bedside and in laboratories the signs and symptoms of disease, that they may acquire the technique of the therapeutic measures. He would omit, he said, from his address all reference to the personal characteristics needed for the work of a doctor, while emphasising at the outset the importance of the human aspects of our calling. He would make the scientific side of clinical medicine his theme. He continued:—]

THE SCIENTIFIC SPIRIT AND CLINICAL MEDICINE.

The student of 50 years ago almost always entered upon his studies with the intention of taking up some branch of practice or of entering one of the public services. Few alternatives were open to him. There were no bacteriologists, pathology was synonymous with morbid anatomy, and the men who, from the end of the eighteenth century onward, had laid the foundations of biochemistry in this country were all practising physicians. They, and others of scientific bent, pursued their researches in the period of waiting for practice and in its intervals, but nevertheless they were pioneers, not only of the medical, but of other sciences also.

Nowadays the position is very different. In addition to the physiologists, most of whom still go through the medical curriculum, not a few qualified men turn aside from the path of practice and devote their lives to teaching and research in the various branches of pathology or in pharmacology.

This has its advantages and its disadvantages. On the one hand, some men of scientific tastes and interests—for whom the work of the laboratory has great attractions, whereas the practice of medicine has none—enter the profession, and by their researches contribute greatly to the advance of our science and art. In that way medicine is the gainer. But, on the other hand, there is real danger that the great majority of men of scientific bent will turn aside and desert clinical work, in order to devote themselves to work in the laboratory. This tendency is increased by the attitude of some of the laboratory workers, who regard clinical medicine as a subject hardly worthy to attract men of scientific ability. So there has been a drift apart of the ward and the laboratory, which is far more pronounced in this country than elsewhere, since it is only recently that complete clinical units, with wards and laboratories under a single head, with trained assistants, have been established amongst us.

It will be my endeavour to convince you that here is abundance of work to be done on clinical subjects by strictly scientific methods; and seeing that much of the information to be sought can only be got by clinical research, it would be nothing short of a disaster if all, or nearly all, those qualified by tastes, training, and opportunities to pursue clinical investigations on such lines should desert the wards for the laboratories.

The study of pure pathology and of the problems of immunity entails experimental investigations by men highly trained in the subjects and the methods employed, in bacteriological technique, and chemical manipulation. Those who devote their lives to such work are most valuable members of the profession; but, on the other hand, the mere fact that a piece of work is done in a laboratory does not make it a scientific research. The routine of clinical pathology is not more scientific than the examination of a chest, the diagnosis of a lesion of the brain, nor even than the careful taking of notes at the bedside.

It is not to be expected that everyone who enters upon the practice of medicine will approach his work in a strictly scientific spirit and with zeal to contribute to the advancement of knowledge, although he must employ scientific methods. It must needs be that the bulk of the members of our calling will, owing to the incessant demands upon them, have little time or opportunity for investigation on broad lines. They must be content, willy-nilly, to carry out the day's work with practical skill and common sense, making good use of what they have learnt from their teachers and from their own experience. Yet not a few of those so circumstanced make important contributions to medical knowledge.

On the other hand, it must not be forgotten that the knowledge upon which the art of medicine is based has been gained by work done on scientific lines, by methods of observation and experiment. All the great therapeutic advances of recent times have been the outcome of scientific investigation; and in medicine, as in other sciences, investigations carried out with no practical aim have proved very fruitful in practical results. It is to scientific research that we owe aseptic surgery and all that it has rendered possible, the conquest of insect-borne diseases, the banishment of the typhoid terror from campaigns, the discovery of the vitamins, and the utilisation of hormones. No better example can be quoted than the history of insulin, from the experiments upon dogs of von Mehring and Minkowski to its widespread benefits in the present day.

[Having referred to the crowded state of the curriculum and deprecated any suggestion that it should be lightened by less attention to anatomy and physiology, Sir Archibald Garrod pointed out that the aims of the practitioner, though they are immediately the making of a diagnosis and the discovery of the appropriate therapeutic measures, must go beyond these; there is the study of disease as it manifests itself in the living human subject—the gaining of new knowledge for the advancement of medicine. Of the science of diagnosis he spoke as follows:—]

THE MEDICAL CURRICULUM AND THE SCIENCE OF DIAGNOSIS.

The science of diagnosis is, in the main, a science of observation, the aim of which is to detect in the living patient processes and lesions which are beyond our reach, but which would, in most instances, be revealed at a post-mortem examination. Yet it rests largely upon post-mortem teachings, and all who aim at becoming capable diagnosticians should take advantage of every opportunity afforded to them of seeing, and whenever possible conducting, such examinations. Such opportunities are most common during student days, and only too many of us regret in after life that we have neglected them; for morbid anatomy, one of the most important subjects in the medical curriculum, can only be learnt by personal observation. Do not forget that there is an immense difference between facts which we *know* and facts with which we are merely acquainted. Facts which we know are not those about which we have read, or have heard lectures, but those which we have observed, apprehended, and confirmed for

*With the consent of the authors all these introductory addresses are reproduced in somewhat abridged form.

ourselves. We need no *memoria technica* to recall a fact which we *know*.

Some diagnostic methods are simple and involve merely the use of senses—of our eyes, ears, nose, and fingers; others require the use of instruments of more or less complexity; and others, again, involve chemical or bacteriological examination of the blood or excreta, by methods usually carried out in the laboratory. It is hard to realise how recent most of our diagnostic methods are. Auscultation and percussion were only brought into use at the end of the eighteenth century; the clinical thermometer came into general use in our hospitals as recently as the 'seventies of last century. Blood counts began in the same decade, and the importance of leucocyte counts was only recognised in the 'nineties. Since then our diagnostic resources have been largely increased. The discovery of the tubercle bacillus, and its ready detection in the sputum of many sufferers from pulmonary tuberculosis, opened the way for wide applications of clinical bacteriology—the detection of various bacteria on the one hand, and the agglutination tests on the other. More elaborate means, such as the Rontgen rays and the electrocardiograph, have rendered our findings far more precise, and we now have methods of testing the functional efficiency of such organs as the liver, kidney, and pancreas.

As long ago as the middle of the last century uric acid was detected, and estimated, in the blood of the gouty, but in recent years methods have been devised which render possible the estimation, not only of uric acid, but also of glucose and urea, in small specimens of blood from a prick in the ear.

All these refinements and advances have not superseded the older and simpler methods. It is as necessary as it ever was that the medical man shall be trained to make use of all his senses, supplemented by the stethoscope and thermometer. A laboratory is not always within reach, and it is often necessary to act before a bacteriological report can be had. Moreover, the older methods have been improved, and pulmonary tuberculosis is now usually diagnosed by auscultation and percussion at a stage at which it would have escaped recognition 50 years ago.

Auscultation and percussion are strictly scientific methods. Consider for a moment how by such means it is possible in very many instances to ascertain beyond all doubt that a patient's lung is consolidated, or that his pleural cavity contains fluid; that his heart is hypertrophied or dilated, or that there is narrowing of a valvular orifice or leakage of a valve. Such diagnoses involve accurate observation and sound interpretation of the signs observed, and the confidence with which we make them is due to confirmation of such diagnoses at many post-mortem examinations.

Lesions of the nervous system often present difficult problems of localisation, for the brain and spinal cord are wholly out of reach of direct examination. Yet by making use of the findings of experimental physiology, and the teachings of morbid anatomy, it is usually possible to make a correct diagnosis of the seat and nature of a cerebral or spinal lesion; just as a man who is thoroughly conversant with the telephone system may, by comparison of observations made in several branch offices, diagnose accurately the place, and form a shrewd notion of the cause, of an interruption in a central office which he cannot visit.

A diagnosis often involves replies to two questions—namely, Where is the lesion? and What is its nature? —but the answers often hang together. For example, the signs and symptoms, in a particular case, point to a lesion of the head of the pancreas, and experience teaches that such a lesion is almost certainly a carcinoma. Yet a diagnosis may be right in one respect and wrong in the other.

There are some people who possess a natural diagnostic insight, and others who acquire such an insight by long experience. The accumulated impressions, derived from cases seen at various times, may point to a right solution. Just as a child spells out the letters of words, and a beginner translates laboriously what he reads in a foreign tongue, so the medical student runs over in his mind the possible causes of an observed sign or symptom. But experience allows such conscious effort to be dispensed with, the foreign words come to convey their meaning directly, the clinical picture points to a correct diagnosis.

One of the dangers which beset the medical student of to-day is that he may be tempted to neglect that thorough grounding in auscultation and percussion and the simpler chemical and microscopic tests which can be made at the bedside, and may come to rely upon reports from the laboratory of examinations which he has not himself carried out. To this danger all examiners in medicine and surgery are keenly alive.

MEDICAL TREATMENT AND NATURAL FORCES.

[Coming to treatment, Sir Archibald Garrod alluded first to the advances in surgery rendered possible by Lister's researches, and indicated that the physician, while unable to obtain definite results comparable to those which follow, for example, the removal of an inflamed appendix, has to help the patient to hold his own whilst Nature works a cure. One of the most important lessons learnt during the last half century was that Nature has provided the patient with power to produce far more potent drugs than any used by our forefathers, but that their utilisation demanded the keenest pursuit of clinical research. The extensive use of serums and vaccines represent, he said, the attempts to utilise Nature's own remedies, and he trusted that in due course it would be possible to give them as pure products and free from undesirable admixtures. The study of dietetics and the discovery of the vitamins, the employment of Rontgen rays, radium, and its emanations, light and ultra-violet rays, electrical treatment, massage and manipulative measures, as well as the nursing methods of the present day he alluded to as the great modern additions to the weapons against disease.]

PURSUIT OF CLINICAL RESEARCH.

So far I have spoken of scientific knowledge and method, as applied to the recognition, control, and treatment of disease, but what I particularly wish to emphasise is the fact that the clinical observer has abundant opportunities for the study of disease as seen in the human subject—in other words, for the pursuit of clinical research. Much of the knowledge so obtained is not to be had from experiments on animals; for a human patient can describe his sensations with greater or less accuracy, and can tell us of the medical history of himself and his family. Such work as that on the sensory nerves which we associate with the name of that great observer, Henry Head, could not be done in any other way.

Although it is established that, in the majority of instances, illness results from the invasion of the body by micro-organisms, vegetable or animal, or by poisons of inorganic origin, and although such immense help has been got from the culture and study of such organisms and of their effects upon lower animals, and by the experimental study of the phenomena of immunity, we cannot learn in the laboratory all that we need to know about disease.

What we call disease is the response of the organism to the invasion of the agents of disease, and, seeing that no two individuals are exactly alike either in structure or in chemistry, sickness does not conform to any single model; each individual case calls for careful observation. Owing, as I believe, to their chemical individuality, different human beings differ widely in their liability to individual maladies, and to some extent in the signs and symptoms which they exhibit. Hence it will be found a useful maxim that there is no such word as "never" in medicine. Rules which appear to be immutable turn out to have their exceptions.

Many idiosyncrasies are obvious and notorious, such as the sensitivity of individuals to special drugs, or particular articles of diet, which have no ill-effects upon others. As examples may be quoted the manifestations of sensitivity to proteins, seen in the various forms of urticaria, in hay fever, and in varieties of asthma. Light also is an agent which affects various individuals in very different ways. Usually beneficent, it produces unpleasant effects upon the skin of some individuals, and to a very few who are victims of congenital porphyrinuria it is a veritable poison.

Again, the minor injuries which are necessary accidents of the wear and tear of life vary greatly in their effects. In the bleeder a trifling knock may produce grave trouble in a joint; in victims of that strange anomaly fragilitas ossium it may cause a fracture; in a gouty subject it may induce an attack. So do our idiosyncrasies and our circumstances contribute to the moulding of our maladies. All this is the true basis of the doctrine of diatheses now unduly neglected.

THE GREAT PIONEERS.

[Here the lecturer, recalling that by clinical observation, controlled by morbid anatomy, almost all the maladies with which we are familiar had been differentiated, enumerated the work of certain pioneers in clinical research whose studies had led to particularly progressive results. Among the famous men whom he particularly brought to the attention of his hearers was Thomas Addison, who was able to diagnose by the close observation of a certain group of associated symptoms, disease of the adrenals, a condition where the diagnoses could be verified in the majority of cases by autopsies. His next example was William Jenner, who differentiated typhoid and typhus fevers from close observation of a series of fatal cases of continued fever which had come under his own observation, in all of which autopsies had been made. He spoke, in connexion with neurology, of Hughlings Jackson, whose "contributions to science, from the discovery of the association of convulsive attacks with lesions of the cerebral cortex to the wide and important generalisations upon which his fame largely rests, were the outcome of bedside observation controlled by morbid anatomy." Other names in the list were those of Parry, Graves and Basedow in connexion with exophthalmic goitre, Brown-Séquard, Marie, Fröhlich, James Paget, Jonathan Hutchinson, W. B. Cheadle, and Harvey Cushing; and he concluded by pointing out to the students that, despite the wonderful work done by these pioneers or because of the new vistas opened out by them, there are still large blank spaces in our knowledge to be filled.]

SCOPE FOR SCIENTIFIC WORK IN CLINICAL MEDICINE.

If, as I have tried to convince you, there is abundant scope for scientific work in clinical medicine, why is it necessary to point this out, and why do we so often hear the contrary opinion maintained, especially by laboratory workers? Is it not because medical men too often do not realise the requirements of scientific method? If we are to hold our own as members of the army of research, we need to see that our work is up to the required standard; that our observations are sufficiently precise, and are confirmed by the method of control; that our statistics will bear examination by statisticians, people whom it is not easy to satisfy, and that our hypotheses are legitimate inductions from facts which are clearly established.

There are, however, obvious difficulties which make it hard and often impossible for the clinician to be as exact in his methods as he would wish. Medicine is always in a hurry. The patient and his friends are only too apt to mistake scientific caution for incompetence; to demand a cut-and-dried diagnosis in an impossibly short time; and to estimate a ready dogmatism above a reasoned uncertainty. Time is often pressing, and the doctor is obliged to act upon very incomplete evidence, lest, whilst he waits for certainty, valuable hours may be lost. He cannot always put his treatment to the test by trying one measure at a time; and, again, he is bound to forego any diagnostic test, or even a thorough examination, if it appears to him that it might in any way be harmful to the patient. These are only a few of the hindering factors which are familiar to all practitioners.

You will have to realise that to a large section of the public all science is under suspicion, and scientific medicine is distrusted. A profession which makes a free gift to mankind of all its discoveries is widely regarded as a close corporation of people who look askance at men cleverer than themselves, merely because they have not a medical education, or because they base their treatment upon heterodox theories. This phase of thought is by no means helpful to him who would advance the knowledge of disease, and, through knowledge, its treatment.

In conclusion, let me repeat that for the clinician, as for the laboratory worker, and especially for both working in coöperation, there is abundant scope for original investigation—that highest product of the scientific spirit. We are not all built to do such work, and there are excellent investigators for whom an obvious practical aim is a necessary stimulus to research; but for those who are content to seek knowledge for its own sake there are great rewards; for the discovery of a new fact, however small a one, or the framing of a conception which throws a beam of light into some dark corner, brings a satisfaction which is without alloy.

Yet the way of the investigator is rough, and there are many disappointments to be faced. In the words of Ecclesiasticus:—

> "For at the first Wisdom will walk with him by crooked ways and bring fear and dread upon him, and torment him with her discipline, until she may trust his soul and try him by her laws. Then will she return the straight way unto him, and comfort him, and show him her secrets."

May she show her secrets to those of you who elect to tread her path.

PROFESSIONAL CAREERS.

An Address delivered at the Opening of the Winter Session at King's College Hospital on Oct. 1st, 1926,

BY SIR HUMPHRY ROLLESTON, BART., K.C.B., M.D., F.R.C.P.,

REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE, AND CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL.

[Sir Humphry Rolleston commenced his address with a warning against too early specialisation, inasmuch as the medical profession presented for its acolytes a wide choice of activities, comparing in this respect favourably with other professions. He continued:—]

In the first place, with the expansion and rapid development of medicine, there are more opportunities and varied openings than ever before. Secondly, apart from accidents, illness, and grave misconduct, a competence or living wage is within the reach of practically all qualified medical men who choose to work. The panel system has, in spite of the initial forebodings and opposition, really improved conditions for the rank and file of the profession. As a profession medicine does not bring wealth or a great position to more than a few, while it has an immense amount of gratuitous work to its credit, and is exposed to the frequent danger of infection from attendance on the sick and the occasional risk of vexatious legal actions for supposed malpraxis and improper certification of the insane. To enter on the physic line as a means of livelihood is justified by the results, but as a path to great material prosperity the way is long, treacherous, and may land the traveller in a slough of disappointment. In spite of Sir Robert Peel's dictum that "Nothing is so misleading as facts except figures," it may be a comfort to remember that statistics got out at various dates by Sir James

Paget, Sir Squire Sprigge, and Mr. E. M. Corner show that on an average over 75 per cent. of medical students obtain a qualification, and that according to the first two authorities 66 per cent. of those qualified have reason to be satisfied with their professional success.

[Contrasting the financial rewards of the medical and legal professions, he pointed out that, though the number of briefless barristers was large, the prizes at the Bar were greater and more numerous than in medicine, the position agreeing, therefore, with Adam Smith's dictum that in a perfectly fair lottery those who draw prizes should gain what is lost by those who draw blanks; as the vast majority of medical men succeed in earning a living the winners of great prizes should be exceptional, and so it is. Of the work of the great majority of the medical profession he spoke as follows:—]

General Practice.

General practice is still, in spite of increasing specialism, the future field of activity for the largest number—probably three-quarters—of qualified medical men, and there is plenty of scope and opportunity. Any medical man or woman can be on the panel for the 15,000,000 insured persons in England and Wales, and the financial and other conditions on the panel are superior to those of its predecessors the clubs and friendly societies. In England there are at present 12,696 men on the panel, or nearly half (46 per cent.) the estimated 27,600 men practising in England, but there are only 434 women on the panel, or one-fifth (19 per cent.) of the 2209 women in practice. For these figures I am indebted to Dr. Smith Whitaker, of the Ministry of Health. This rather striking difference in the sex personnel of panel practice may be in part due to women preferring to confine their work to their own sex and to children. But this is not the whole story, for unfortunately at present the public as a whole have not become accustomed to women doctors and as a rule the panels of women doctors are not crowded. Time no doubt will cure this, as other inequalities, but in the meanwhile women doctors are not finding it so easy to earn a livelihood in general practice as their brothers. The profession received a large influx of women during and of both men and women after the war, and the peak of the wave in qualifications has only recently been reached, so that there is some reason to fear a temporary overcrowding in the profession. A number of official posts in public health, infant welfare, and so forth in this country, in India, in the Zenana Mission, and elsewhere in the mission field are available, in which women doctors can find congenial occupation and a living. It is sometimes thought that the public medical services encroach on the general practitioners' preserves, and in time will lead to their exclusion. But Sir George Newman, who is in the best possible position to know, points out that in reality the reverse is true—

> "For the Poor-law Medical Service has 4000 medical officers for outdoor medical relief, practically all of whom are private practitioners; the post office list of 3500 medical men are all practitioners; out of 1450 medical officers of health, 1100 are private practitioners, and only 350 are whole-time officers; of the 1800 medical men engaged by local education authorities in the inspection and treatment of school-children, 1000 are in private practice; of 1770 certifying factory surgeons, all, hardly with exception, are private practitioners; and the whole of the national insurance service is in the hands of private practitioners."

Some other lines of work allied to general practice may be briefly mentioned. Examining for life insurance is usually a small item in a general practitioner's life, but some men by holding appointments under several offices spend most or even all of their time in this work. It is, of course, true that the chief medical officerships of large insurance companies are usually held by consultants and hospital physicians.

With the progress of medicine to a preventive standpoint the logical importance of establishing periodic overhauls of the adult population may be expected to be more widely recognised and acted on, as in this way the causes of early disorders may be removed and so the sequence of serious results prevented. If and when periodic overhauls, twice or three times a year, become recognised in much the same light as a visit to the dentist is now, a fresh line of work allied to insurance practice will be opened up. Police surgeoncies and appointments to big business firms, to look after their staff, again are nearly always part-time occupations, but in the future it is probable that industrial medicine will bulk more largely than it does at present and provide more berths for medical men who will devote their whole time to this branch of work, which provides much opportunity for interesting investigation. A good example of this is the recent recognition of squamous-celled carcinoma, usually of the scrotum, amongst the "mule-spinners" or cotton operatives, who during their work lubricate with a mineral oil the spindles of the spinning mules. The Home Office's Departmental Committee Report (1926) records 539 cases, 450 of the scrotum.

[Sir Humphry Rolleston next categorised the factors which determined the choice of general practice. Some men, he said, were individualistic and desired to be under no bureaucratic or regimental control; some were influenced by heredity—here he instanced "Georges Clemenceau," the medical ex-Premier of France, and the seventh medical member in lineal descent of a family which followed the profession for 300 years without a break; while the desire to earn sufficient income for marriage was another factor to be taken into account. He continued:—]

Development of General Practice.

With the changes time has brought about, men in general practice who become the guide, philosopher, and ultimately familiar friend of their patients whom they bring into and see out of the world, have also changed, for their medical education and general equipment have greatly improved. They have thus become less dependent on the help of specialists and consultants with whom to some extent they therefore compete. It has been thought by some that eventually general practitioners will become squeezed out by specialists and consultants on the one hand and on the other hand by preventive and social medicine, such as school, tuberculosis, and venereal clinics, and maternity and child welfare centres. But the general practitioner is the essential element in the medical service, and his elimination would be a most serious loss. Just as they have altered in the past so should they accommodate themselves to changing conditions to a larger measure of team-work, to a greater share in preventive medicine, and to take their part in public health organisation. A general practitioner has to possess a knowledge of every branch of medicine, in fact to be in miniature an all-round specialist with the proviso that he also knows his limitations—what he can safely do and what he should leave to others; for in these days, with the great and ever-increasing complexity of medicine, a real all-round specialist is, of course, impossible. This difficulty has to some extent been met by team-work; firms of general practitioners so constitute themselves as to cover the ground of the various branches of medicine, surgery, and gynæcology more or less completely, each partner devoting himself to some particular line of work. Thus in choosing a new partner consideration is given to applicants with such qualifications as a special surgical or even radiological bent, and the existing partners may from time to time take post-graduate courses so as to become recognised locally as experts in the diseases of the throat, eye, urology, and so forth. It is thus possible for a general practitioner to develop into an expert specialist and eventually to set up in a big centre; indeed, his all-round knowledge of the whole art of medicine is a very valuable asset to him as a specialist.

[After pointed allusions to the competition in the sphere of everyday medicine of "amateur doctors" and to numerous cults or "stunts," he warned his

hearers against the too easy dismissal of everything that does not appear orthodox, inasmuch as what in one generation is regarded as the obsession of a crank may subsequently become recognised as a valuable form of treatment. In this connexion he recalled to his hearers the essential part often played in extra-professional success by the imagination of the patient and the force of suggestion, quoting Oliver Wendell Holmes as follows: "So long as the body is affected through the mind no audacious device, even of the most manifest dishonest character, can fail of producing occasional good to those who yield it an implicit or even partial faith."

Sir Humphry Rolleston went on to analyse the prospects and promises of the careers, other than in general practice, open to medical men:—]

SPECIAL CAREERS.

Careers in the Services.

In the past men sometimes entered our profession because, being debarred by bodily defect or failure in negotiating examinations from the executive branches of the army or navy, their ambitions were to some extent met by being medical officers in the services. The call of adventure and itch to travel attract some entrants into the fighting and colonial services; a life of varied interests, an assured rate of pay, and the prospect of a pension to provide for retirement also weighed in the choice of the services, but the shortage in the services at the present time, possibly an aftermath and revulsion from the war, shows that these factors are somewhat in abeyance, and accordingly short commissions of four years or so with a gratuity on leaving, which helps in starting a practice, have been established. The opportunities for research and investigation have much increased in the naval and military medical services, and that devotion to scientific work is compatible with gaining the highest offices in the medical department of the army was shown by the appointment of the late Lieutenant-General Sir William Leishman as Medical Director-General. The new problems in connexion with aviation attract keen men of the kind wanted in the Royal Air Force. Tropical research with its great potentialities is specially open to those in the Colonial Service.

The increasingly active *health services* provide a large number of official positions, not only part-time which, as already mentioned, are chiefly occupied by general practitioners, but whole-time appointments, and these posts are likely to increase in number and importance. Appointments in fever and mental hospitals and sanatoriums are, of course, whole-time, and provide opportunities for research and openings for men who are attracted to these special branches of medicine.

Careers as Specialists.

Wise specialism is of the greatest advantage for the progress of medicine, but its followers should know something about everything medical as well as everything about their own branch. Without taking a reactionary view, there is a danger that specialism may be exaggerated and that parts of medicine which should be within the reach of every competent medical man may be prematurely elevated into a specialty; in ancient Egypt there was a phase (500 B.C.) when each disease had its practitioner who confined his activities to that one condition. To be a clinical specialist has mercenary advantages, for practice comes earlier and the lucrative rewards may be considerable.

The *pathologist*, *bacteriologist*, *serologist*, and *biochemist* belong to a special branch of medical practice which has a progressively increasing scope of activity, as is shown by the overwhelming flood of new work on these fundamental sciences; from a material aspect the recommendations of the Royal Commission on Health Insurance, if carried into effect, will increase the number of official posts available for those whose abilities and temperament render them better suited for laboratory investigations than for clinical practice, and who, therefore, prefer the quiet pursuit of truth in the laboratory to that of wealth in a limousine or a Ford. Intellectually, laboratory research with the possibility of making a permanent addition to knowledge which will advance scientific medicine and so benefit suffering humanity, has an appeal of the highest order, and all honour to those who are able and willing—for we are not all so gifted—to follow the call. It can hardly be too often emphasised that in the best interests of all concerned the clinician and the laboratory worker should be in constant and close touch, and, indeed, in the whole-time directors of professorial units they are combined. The laboratory worker should for his own sake have a full and experienced training in clinical medicine.

[After brief allusion to the work of the anæsthetist as a branch of therapeutics not so sharply marked off as a specialism, and to the new and particularly special work done in radiology, he continued:—]

Careers in Consulting Practice.

Consulting physicians and surgeons, though often dubbed "specialists" by the public, are not usually regarded by their professional brethren in the same category as those who practise ophthalmology, gynæcology, laryngology, otology, psychiatry, orthopædics, and other legitimate specialties. The general consulting physician and surgeon have had their wings somewhat clipped by the growth of specialism, and, indeed, hospital physicians now commonly pay more particular attention to some branch of their subject, such as diseases of the heart, lungs, nervous system, or alimentary canal. It is more especially the general consulting physician who has suffered, and the wait for monetary success may be so long that without private means the struggle is disheartening. Few consulting physicians were more successful than Sir Andrew Clark (1826–93), who said that he had to work ten years for bread, ten years for bread-and-butter, and 20 years for cakes and ale; it is not given to all to practise for 40 years, or if they do to reach the material rewards of the last stage. Money may be a mark of success, but there are other conceptions of success, and it has been written "What shall it profit a man if he gain the whole world and lose his own soul?"

With surgeons the outlook is very different, for their technical skill in operating has been enabled by the discoveries of anæsthesia and antiseptic and aseptic methods to become most successful in combating disease in all parts of the body, especially cancer and acute inflammation in the abdominal organs. But in large centres surgeons are largely concentrating their activities on some group of disease, such as the abdomen, malignant disease of the breast, surgery of the brain. Of the two great, if artificial, divisions of the healing art, pure medicine and surgery, the second is naturally the more attractive, for the benefits wrought by operation are much more obvious and spectacular than those in a physician's practice. The operating surgeon has invaded, and with good justification, realms of disease formerly regarded as sacrosanct to the physician, and the rewards are much greater; thus gynæcology in its advance has become surgical, and much of the treatment of digestive disorders is on operative lines. A budding gynæcologist should now be a Fellow of the Royal College of Surgeons. Time was when the physician was paramount, but now there are not wanting definitions of a surgeon which point to his supremacy, such as "A surgeon is a physician who can use his hands," "A surgeon is a physician and something more," and perhaps the arresting, if somewhat intriguing, autodefinition of the distinguished President of the Royal College of Surgeons, "A physician doomed to the practice of surgery." The financial rewards are much greater and begin earlier than in the physicians' earthly course, but on the other hand a surgeon's flood of activity ebbs sooner, and the wear and tear of a surgeon's exacting life are much greater than in the case of his medical brother; writing last year about this subject as illustrated by the staff of the Manchester Royal Infirmary in 1900, Mr. A. H.

Burgess pointed out that the death-rate on the surgical side was nearly five times higher than among the physicians. The future of the general surgeon is a matter for careful consideration by those who are thinking of reaping a harvest 20 years hence. The various specialties, laryngology and otology and proctology, which tend to spread from the orifices further into the alimentary canal, orthopædics, genito-urinary and venereal diseases have narrowed the former vista of the general surgeon. Further, if, as is within the bounds of imagination, discoveries such as that of Gye and Barnard lead to prevention and cure of cancer, and the immunology of the future to the prevention of inflammation of the vermiform appendix, gall-bladder, and other forms of inflammatory abdominal disease, the activities of the operating surgeon would be greatly curtailed and little more than accidents and deformities would remain.

[Sir Humphry Rolleston then pointed out that the differentiation between physicians and surgeons was artificial in principle, and closed as follows, repeating the warning against the precipitancy in the choice of any particular side of the medical career :—]

It is better to utilise a year or so at the beginning of the waiting period, when the mind is elastic and fertile in ideas, to do some work of permanent value. So often a man seizes the opportunity of gaining an assistant physiciancy or assistant surgeoncy at a hospital without a medical school and becomes a slave to seeing out-patients in an unprofitable race against the clock, when by spending the same time in experimental research he would establish a claim to a better appointment, even though he may appear to be somewhat later in the start of the race with his peers.

THE FUTURE OF WOMEN IN MEDICINE.

An Address delivered at the Opening of the Winter Session at the London (R.F.H.) School of Medicine for Women on Oct. 1st, 1926,

BY SIR WALTER FLETCHER, K.B.E., F.R.S., M.D., F.R.C.P.,

SECRETARY OF THE MEDICAL RESEARCH COUNCIL.

Dr. J. G. Adami, Vice-Chancellor of Liverpool University, whose death so lately has brought very heavy loss to a host of friends and to many good causes, was to have delivered the opening address. He would have brought some encouraging greeting and good counsel, ripened by a long life of active work in research, in teaching, and in administration, at Cambridge, at Montreal, and at Liverpool. I owe him a heavy personal debt for his constant and warm-hearted friendship. He showed this to me, then a stranger to him, when I was a freshman only a few days old at Cambridge, at a time when he was a Fellow of Jesus College, elected there after his work with Roy on the mammalian heart. Later at Montreal, as professor of pathology, later again during the war, when I worked in very close touch with him in some directions, and finally at Liverpool during his many-sided work there for the University and for education, he never failed to show me, as he showed to all, an instant sympathy and an eager impulse to help and to give rather than to take. His high technical achievements are well known and have been lately well described. His success at Liverpool in his work for the University will become increasingly recognised and measurable as the long harvest follows his sowing. But I think that if we had any right means of calculation we should probably come to know that his greatest service of all lies really in the unseen chain of events flowing from his innumerable and unrecorded acts of unselfishness and of kindness.

Our chief object, I take it, is to greet and cheer members now beginning work here and to welcome them into the common fellowship of work and study in this place. To do that is both easy and agreeable, and may I congratulate your freshmen upon entering their apprenticeship to a profession which has so much to claim and so much to offer for any who join it with the right qualities of mind and heart ?

But it is expected that our greeting should be coupled with some kind of friendly admonition or advice, and it is here I feel that the difficulty begins. I am not troubled by the general dubiety of giving advice. You will remember Lord Morley held that there were two kinds of fool in the world—those who give advice and those who take it. We can evade that condemnation by giving not direct advice but helpful information. Yet what accurate information about the coming years can we now give to inquiring beginners ? What the freshmen now seeks, surely, is information about the probable professional opportunities open to her in the early and distant future, so that she may take the best way to making the most of her powers. The difficulty of helping her is the difficulty of forecasting the future, and I think that the problems here are more pressing and more puzzling at the present time than ever in the past.

GENERAL AND SPECIAL PROBLEMS.

We are faced by two sets of problems : those which belong to all medical education, as well as those special problems which belong to women as such. The very rapid development of science in the past generation and its growing application to medical practice are making it year by year more difficult to predict the course which medical practice is likely to follow in its next progress and to direct the lines of medical education more fitly to their ends. Great changes are taking place, and the rate of change is likely to become more rapid rather than more slow. The progress of surgery, of which the development in the last generation has been so phenomenal, seems likely now to follow the law of diminishing returns and to be approaching something like stability. If science, indeed, could give us preventive control over cancer the volume of surgery would at once be immensely reduced. It is not very bold, again, to think that the physician is likely to find his powers and scope changing rapidly in many ways as we lay hold of the elements of a scientific knowledge of nutrition and begin to use its enormous latent powers. The work of preventive medicine in all its branches is in a period of great expansion, and many new forces are now at work which will open up the possibilities of extending this throughout the Empire and of removing the long-standing waste and disgrace of preventable but unprevented disease under the British flag. The growth of biochemistry holds obviously untold possibilities, some almost within our grasp, which, when applied to human affairs, may deeply affect the future of medicine and indeed may bring startling changes to the whole of our social structure. In large and in detail the problems of the kind thus briefly indicated must be in the minds of all those who are serious about medical education.

THE MEDICAL EDUCATION OF WOMEN.

All these general considerations, of course, are relevant to women's education no less than to that of men. But I would venture to urge now that there are problems of women's education in medicine which are not the same problems as those for men, and that women should resist the present assumption that their medical education should follow exactly the lines laid down for men, and that their outlook towards their future practical work should be the same. Hitherto the medical education of women has followed in almost every detail the traditions and practice evolved for men. This has been an historical necessity. The early pioneers of women's medical education had no choice. I need not in this place touch on the history of this great movement, so well known to all here. It was a movement of which some of the great leaders have their names enshrined for ever in this school. *Si monumentum requiris circumspice.*

The battle now, however, has been fought and won, and almost complete freedom has been gained for

the future development of women's medical education. The time seems to have come when close parallelism at every stage of the medical education of men and women should no longer be assumed. Better reasons, at least, must be found for it than custom and convenience, which sprang from older necessity. It may be that to maintain too close a parallelism is wasteful and even disastrous. As biologists we cannot fail to be awake to this. "Male and female created He them." We should be slow to think that the very best powers of a woman can be developed and employed by following exactly the same course and by working in just the same fields as those in which the best powers of a man may be brought out. We must believe that the highest service of each will be given in differentiation of function, and that coöperation between man and woman, each working in the best sphere, is to be far preferred over rivalry. Closer adaptation of the nature of the work to the qualities of the workers by no means involves any inequality or any lowering of intellectual standards. On the contrary, it is likely to call for higher standards on each side and to give room for effort which will be more effective because it will be more intensive.

I touch upon these problems here with the greatest diffidence. I am much more certain of their existence and importance than I am of the right way to their solution. When I speak of divergence or differentiation in the educational courses to be followed by men and by women, I am thinking, of course, of the whole period of training, and more especially of post-graduate training. How far, or at what points, or if at all, there should be a difference in the minimum courses for qualification are other problems not now considered. I am thinking rather of what a woman student should be inclined or recommended to select than of what she should be made to do by regulation.

In this matter we should think first of the fields of work specially appropriate to either sex, and without looking at all closely now to see where the exact boundaries of the fields may lie. It seems to me obvious that the rough and tumble, if I may use those words, of general practice make it much less suitable as a general rule for women than for men. It seems evident, too, that only exceptional women are likely to join with men on equal terms in specialised surgery. It will be long, to give another instance, before medical work in the tropical and many other parts of the Empire will be so suitable for women as for men.

THE SCOPE OF WOMEN IN MEDICINE.

On the other hand, there are large fields of service calling peculiarly for the special gifts of women, in which it seems to me that they could give far more abundant and more progressive service than is given now. I think here specially of the study of nutrition, of children's diseases, and of maternity in all its phases. Here are immense fields offering problems of the greatest interest, and giving opportunities for service of inestimable value both to the individual and to the nation. Closely linked with these are the possibilities of work in preventive medicine, in the study and management of child welfare, whether in the city, in the school, or in the factory, and in all the applications of physiology and medicine to the lives of women and children engaged in industrial work.

Problems of Nutrition.

I said earlier that the first beginnings of our knowledge of nutrition were already promising to affect deeply the practice of medicine. Is not this a direction in which women should strive to make themselves, so to speak, mistresses in their own house?

It happens here that much of the basic knowledge we are beginning to collect has been gained in the laboratory by medical and by non-medical women. Miss Chick and her colleagues at the Lister Institute have given invaluable service here by work, more particularly, upon the several vitamins. They gave help of the first importance to our naval and military forces during the war by their work upon the anti-scurvy vitamin C and the vitamin B. Miss Chick, again, and her colleagues, Miss M. Hume and Miss Henderson Smith, together with Dr. E. J. Dalyell and Dr. Helen Mackay, of this School, as clinicians, made valuable studies of rickets in Vienna from 1919–22, and to this expedition we owe among other things the first experimental demonstration that ultra-violet light and the vitamin of cod-liver oil are interchangeable in the prevention or cure of rickets in babies. In the past year Miss Chick, with Miss Roscoe, has shown, by refined and laborious experiments, that the growth vitamin A and the antirickets vitamin D for their abundance or deficiency in cow's milk, depend upon the diet of the cow and its access to sunlight. The growth vitamin depends simply upon the supply of vitamin in the cow's fodder. The cow can only transmit it. But the antirickets vitamin, though it may be supplied in the fodder and transmitted by the cow, may also be manufactured afresh in the cow's body under the influence of sunlight. When we think of the dependence of our industrial populations upon the milk of cows commonly stall-fed and kept in the dark, we can realise the inestimable practical value of new knowledge of this sort.

Another woman, again, and another non-medical woman, Mrs. Mellanby, in following up her husband's pioneer work upon rickets as a deficiency disease, has revealed a fundamental relation between the diet before and during dentition and the formation of teeth, the effects of vitamin deficiency being shown both in damage to their general structure and arrangement and in failure of their minute, invisible architecture—that prismatic architecture of the enamel which gives it hardness and its resistance to disease. It seems likely that this discovery will not only transform our outlook on the national problem of dental decay, but give us the true key to its practical solution.

All these studies and others like them give ground for confident hope of an immense increase in our practical powers of repelling disease and of increasing the happiness and the beauty of our people. Research here is costly, painful, and slow, yet the due application in effective practice even of the little we know already seems often to be slower still.

The new knowledge of the vitamins of milk which we owe to Miss Chick and her colleagues has immediate relevance to the problems of human lactation, to the treatment of the expectant and nursing mother, and the management of breast-feeding. This seems to be a field crying aloud for the better attention of women. If the truth were known I venture to think that my sex has done far too little in the proper advocacy of breast-feeding; men have tended, I am afraid, to throw their influence in fact, if not on paper, rather on the other and the wrong side. But even with the better knowledge and the better weapons that research has given, a man after all can only know and apply the physiology of lactation. A woman may know both its physiology and its psychology, and without a knowledge of both the physician is incomplete.

The application of nutritional study to medical practice, whether curative or preventive, surely offers a field of work peculiarly fitted for women. It is not a soft option. It calls for arduous work and highly technical study; it offers problems of great intellectual interest, and at the same time promises high rewards in practical usefulness. In spite of this, however, it does not seem that any significant body of medical women are turning their special attention in this direction.

Defects in Food-supply in Women's Institutions.

This seems in itself to be a phenomenon worth examining. I would ask you to allow me to touch here upon a point which may possibly have some relevant connexion with it. I will put a bold question and hope that you will forgive my candour. Why is it that women following a communal intellectual life are so prone to neglect both the quantity and the

quality of their own food? It is notorious that, speaking generally, women's colleges and other institutions governed by women provide food which is often inadequate in amount, badly chosen, badly cooked, and badly served. All men who have sisters or daughters at college or some similar place become aware of this. It is not enough to say that women are less greedy than men. The deficiencies I have in mind often take the diet below the minimum for due nourishment, while bad cooking is at least as wasteful and indefensible as greed itself. I venture myself to think that the phenomenon I describe, now perhaps beginning to disappear, was originally due to the intellectual fervour of the movement for women's higher education, and that in the pursuit of high thinking plain living was allowed to become bad living. Here has been a great opportunity for medical women, and I believe that enlightened action from your professional side has still immense potency for helping the nation by improving the food and the health of the very girls and women upon whom our best hopes for the national future depend.

Conclusion.

May I finally touch upon one consideration which must be borne in mind in all discussions of divergence between the medical courses of men and of women? The high function of marriage rarely takes a man out of the profession; it must, on the other hand, in most or many instances, remove a woman from practice. This elementary difference is inevitably a large factor in decisions that have to be made when men and women students stand together in competition for educational facilities within hospitals or elsewhere. Time and money spent upon, say, ten men will go to make nearly ten future doctors. The same effort spent upon ten women must give a far smaller future effective output. I hold myself that few, if any, schemes of education are better than a sound medical education as a preparation and equipment for marriage. It should guide and strengthen a woman to perform "justly, skilfully, and magnanimously," all the high and all the lowly tasks of married life. I think a wise student will see to it that in the absence of special reasons she will try to emphasise in her professional training and work those parts of the subject not only best fitted for a woman if she remains in professional practice, but most likely to be serviceable if and when marriage comes to her afterwards.

I know well that I have touched upon several points still the subject of high controversy. Yet it is those who are most in earnest about the future of women in medicine who will be the most desirous that these problems should be raised fearlessly, and that they should find their discussion and their right solution at a place like this, so rich already in the highest traditions of work and service.

DOCTORS AND THE PUBLIC.

An Address delivered at the Opening of the Winter Session at St. George's Hospital on Oct. 1st, 1926,

By E. GRAHAM LITTLE, M.D., F.R.C.P., M.P.,
PHYSICIAN IN CHARGE OF SKIN DEPARTMENT, ST. MARY'S HOSPITAL.

[Dr. Graham Little commenced his address with a eulogy of the personal and teaching qualities of Dr. Howship Dickinson, under whom he worked in close contact at St. George's Hospital, made the closer because the late Lee Dickinson, Howship Dickinson's promising and only son, lived in Dr. Little's house. He went on to say that in dealing with his subject, Doctors and the Public, he intended to take as the text of his address a letter which appeared in the *Times* of Oct. 23rd, 1925, written by Mr. Bernard Shaw. He said:—]

My illustrious countryman is handicapped, but of course not deterred, by a complete ignorance of the subject he criticises, and perhaps for this very reason is more than ever typical of a great mass of public opinion which the profession will do well to recognise is dissatisfied with many of the circumstances attending the practice of medicine to-day. Mr. Bernard Shaw writes:—

> "Unregistered practitioners are at a heavy premium because they have mastered the modern technique of which registration guarantees ignorance. . . . The G.M.C. has become a trade-union of the worst type—namely, the type in which the entry to the trade and the right to remain in it are at the mercy of the union. Not only is the type the worse, but in this particular instance it is at the crude stage of preoccupation with professional earnings and sullen defiance of public opinion, which produced the Manchester and Sheffield outrages in working-class trade-unionism in the last century."

In condemning the obsolete training maintained by the G.M.C., Mr. Shaw remarks that—

> "There is nothing that the unregistered practitioners do that cannot be done by registered ones, if only they are apprenticed to the techniques of to-day instead of to those of a century ago."

The implications are: (1) that medical education of the present day is ill-designed to meet the needs of the public and compares unfavourably with the training, if that word can be used in such a connexion of some branches of unqualified practice; (2) that the medical profession is ruled by an obsolete and tyrannical code of ethics, administered by a body, the General Medical Council, which ought in the public interest to be forthwith scrapped, and that rulers and ruled are actuated by the most sordid motives of self-interest.

The Work of the General Medical Council.

[Examining these criticisms in detail, Dr. Graham Little pointed out that the General Medical Council, so far from maintaining an obsolete training, has resolutely marched with the times by keeping in the forefront of medical education the preventive and clinical aspects. He said:—]

Although readjustments in teaching both anatomy and physiology may be necessary, those subjects must form the basis of all scientific medicine. Again, with the object of laying greater emphasis upon the ultimate end of medicine—namely, the prevention of disease rather than its cure—the General Medical Council has wisely placed in the very forefront of its resolutions adopted in 1922, with regard to professional education and examination the recommendation: "That throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of medicine." And with the same object of securing the maximum period of study for clinical subjects, these resolutions further recommend: "That a minimum period of three years shall be available for these studies." This period is much more usually four years than three. It is, in fact, in the insistence upon the importance of clinical training that the English School of Medicine has gained its great prestige. . . . . It is precisely in the preposterous neglect of clinical study and the lack of opportunities for pursuing it that the unqualified practitioners compare so very unfavourably with orthodox medical schools. To take one glaring example: The largest osteopathic college in the United States, Kirksville, Missouri, which claims 1000 students, is situated in a small frontier town, the whole population of which does not exceed 4000; one-fourth of this population may be regarded as students of this particular college. The Universities of Oxford and Cambridge, each situated in towns with about 60,000 inhabitants, have wisely regarded the clinical material afforded by such populations as being entirely inadequate for the study of clinical medicine, and their medical students are consequently sent to London for their clinical years. There is no statutory body in the United States comparable to our General Medical Council, and the lack of such an authority accounts for the success of the

bluff by which these colleges pretend to be adequate schools of medicine. Our General Medical Council would, of course, not recognise any medical school as being equipped for clinical study in which the clinical material was limited by a population of 3000 persons.

UNQUALIFIED PRACTICE.

[Dealing with the multiplicity of subjects required by the medical students of to-day, Dr. Graham Little thought that medical education must tend to be more prolonged, it being inconceivable that the time given to the study of the preliminary subjects should be curtailed, while it is impossible to prevent the later subjects becoming more numerous and complicated in sympathy with immense advances in medicine. He drew a parallel between the training of qualified men and that which unqualified persons receive, reminding his audience that in Great Britain alone the legislature encourages unqualified practice, allowing any man to exercise his skill in any branch of medicine or surgery and receive payment without legal penalty unless he should pretend to the position of a registrable qualification. He did not consider that there was any dearth of properly educated medical men in this country making unqualified practice a necessity for the public, seeing the proportion of doctors to the population is 1 to 1400. He continued :—]

The following I consider ought to regulate the attitude of the public towards the medical profession. The words are quoted from a leading article in the *Times* of March last.

"The fatal weakness of the unqualified practitioner is not his lack of a medical degree, but his lack of that knowledge of the disease which, however imperfectly, enables a qualified man to interpret the signs presented by his patient, to distinguish one sign from another, and to relate the signs to prognosis and treatment. Diagnosis, in short, must precede therapy. To contend, then, that the public interest can possibly be served by exempting anyone who is to enjoy the status of a registered medical practitioner from training in those sciences by means of which alone a diagnosis of disease can be made is, on the face of it, ridiculous. There can be no 'back-door' to the Medical Register. Nor can the public suffer for a moment any delegation by doctors of their right to determine the nature of a patient's complaint. Once, however, this crucial matter has been settled and a line of treatment laid down the doctor may delegate, under a general medical guidance, the responsibility of treatment to skilled persons, who do not possess a medical diploma."

The *Times* properly stresses the danger of allowing unqualified and ill-trained persons to undertake the diagnosis of disease. There is another factor than mere ignorance which adds very considerably to this danger and which has not been noticed. At the present day it is more than ever necessary in any case of unusual difficulty that the patient should be examined by several experts, for no one can combine the knowledge which all but the simplest cases require for their elucidation. The unqualified practitioner is by the nature of things debarred from seeking any help whatever. He is afraid to betray his ignorance, or he is met with the real difficulty that reputable persons, quite properly, will not consult with quacks. The result often is that the unqualified practitioner is as isolated in his practice as Robinson Crusoe, and this consideration alone should enlighten the public upon the very real risk of relying upon such isolated and inadequate experience. Notwithstanding these very obvious handicaps to unqualified practice the human impulse to believe the printed word leads vast numbers of the public to swallow both medicine and theories with an equally absurdly misplaced confidence, and the British Isles still enjoy a bad pre-eminence in the consumption of patent medicines as against all other countries, with the possible exception of the United States. Nowhere, indeed, have the quacks more friends than in the present House of Commons, if one may judge by the personal experience I had when bringing in my motion, in February last, for an inquiry into the whole question of unqualified practice, with the object of regulating it. In the very interesting debate which ensued it was amusing to find that speech after speech expounded the thesis that advances in medicine had come invariably from extra professional sources.

The public are, in fact, unaware of the immense strides made in our science and art during the last 30 years, so eloquently described by Prof. Starling.

"When I compare," he writes in his Harveian Oration, "our present knowledge of the workings of the body, and our powers of interfering with and of controlling those workings for the benefit of humanity, with ignorance and despairing impotence of my student days, I feel that I have had the good fortune to see the sun rise on a darkened world, and that the life of my contemporaries has coincided, not with renaissance, but with a new birth of man's powers over his environment and his destinies unparalleled in the whole history of mankind."

The medical discoveries in that period have been far more often made by medical than by non-medical men. The great name of Pasteur is the stick most often used to beat the medical dog, who is accused of having been blind to the significance to medicine of Pasteur's discovery of the causes of putrefaction. But it was Lister, a medical man, who saw its full meaning for surgery, and without Lister Pasteur might very well have passed unheeded by medicine.

INDIRECT ADVERTISING AND COVERING.

[Dr. Graham Little, dealing with the subject of communications to the lay press signed by medical men, thought that the potent influence of the press should be used to disseminate sound expert information which would be useful to uninstructed persons. He was critical of the work of the New Health Society, and in reference to the disciplinary actions of the General Medical Council he said :—]

There can surely be little question that the profession of medicine has advanced in usefulness and in reputation pari passu with the setting up of the General Medical Council. The vast majority of the profession cheerfully accept the ruling of the Council upon methods of professional education and discipline. That the Council in its educational policy follows closely the progress of science is surely very evident from the frequent additions and modification of the curriculum which it initiates; indeed, it is perhaps too ready to accept as gold what is sometimes pinchbeck, and I have hinted at the enormous burden which the addition of fresh subjects throws upon the present student. In its prime duty, that of supervision of medical education, objections to the Council that it lags behind modern advances in science can hardly be sustained. In the matter of discipline I submit that the profession, and not the public, is the best judge as to what degree of control medical men would or should accept—that the control is useful to the public can again hardly be disputed. In the matter of advertisement the Stock Exchange enacts a self-denying ordinance against its members advertising, an ordinance which is clearly of public utility. Medical men should surely enjoy the same privilege of ordering their affairs in this respect as they will. Open advertisement would probably be resented as much by the public as it would be disliked by reputable medical men. In the matter of covert advertisement it is more difficult to differentiate what is legitimate from what is undesirable, but no doubt a via media can be found.

The activities of the Council in restraining the association of registered practitioners with unqualified persons are also greatly misunderstood by the public. It should be emphasised that the offence known as "covering"—that is, the protection which an unqualified man receives from his association with a registered practitioner—may be actually dangerous to the public, and it is from this standpoint that the

Council has framed its professional rule against such "covering." The registered man who breaks this rule does so with full knowledge of the consequences which it entails. Indeed, the consequences are quite frequently desired, inasmuch as a registered man has very much more liberty of action after his removal from the Register, and he is in no way debarred from continuing his practice. He may advertise to his heart's content, and he commonly reaps an enormous advertisement by the mere removal of his name. The unfortunate phrase foisted upon the Council by the wording of an Act of Parliament, "infamous conduct in a professional respect," often creates an unmerited sympathy with the removed person, whose conduct does not appear in the least infamous to the public conscience, by which it is often regarded as a mere breach of professional rule. But if it be kept in mind that this removal means very little more than the omission of the removed person's name from a list of practitioners who prefer to be bound by rules which the removed person wishes to break and does break, much of this misplaced sympathy would be eliminated. It is again to be emphasised that the penal activities of the G.M.C. form only a very small part of its functions.

MEDICINE IN PARLIAMENT.

The comparison which Mr. Shaw makes of the G.M.C. with trades-unions plainly springs from the confusion in his mind between the General Medical Council and the British Medical Association. The latter is a private body which has as much right to make rules for its members as has the committee of a club, and those who do not like to obey those rules have the easy alternative of resigning membership. But the complete inability of the G.M.C. to initiate any disciplinary action is a source of weakness which clearly puzzles the public mind; few laymen understand that unless a change is made in proper legal form by some person or body of persons prepared to take the considerable risk of bringing what amounts to a legal action against the errant practitioner, the Council is powerless to intervene; it acts only as judge, never as prosecutor. In the interest of the public it would seem desirable that some machinery should be provided, such as the institution of a public prosecutor, whose duty it would be to bring the offender to book, and who would be protected from personal loss in the discharge of this duty.

The hostility to the medical profession prevalent in the House of Commons was evidenced by the debate upon my motion dealing with "unqualified practice." It is inconceivable that a similar motion defending practitioners of law from the competition of unqualified practitioners would have met with the same hostility, and of course no practice by unqualified persons pretending to be lawyers is allowed. The reason for this difference of feeling is not far to seek. There are no more than 14 doctors in the present House of Commons; there are something like 200 lawyers. It is difficult to say why doctors should be so poorly represented, and especially doctors in active practice. I believe I may claim to be the only medical man in the House of Commons at present in full and active practice. It should be no more impossible for doctors in practice to be Members of Parliament than it is for lawyers in practice. A man out of practice very soon loses touch with the profession, or, at any rate, ceases to be as representative of medical interests, as the man who is constantly in contact with his fellows. And so I would plead for a more general coöperation on the part of my profession in political problems of to-day, which must, and do, so vitally affect the profession. A certain monetary sacrifice is entailed, more especially because the profession seem to think that when a man goes into Parliament he cannot remain a doctor, and for a consulting physician this may mean serious loss of practice. . . . Action in the House of Commons is far more effective than in any other place, and authoritative information in that assembly, contributed by men engaged in medical work, has never been greater than it is at present.

"EX NIHILO NIHIL FIT."

Abstract of an Address to Students at the Middlesex Hospital on Oct. 1st, 1926,

BY THOMAS YEATES, M.B., C.M., D.P.H.,
COURTAULD PROFESSOR OF ANATOMY IN THE UNIVERSITY OF LONDON.

THE life-history of a successful man, no matter how great, consists of a prolonged, strenuous struggle. Throughout nature every animal is constantly forced to fight for its existence and search diligently for food, and work may be looked on as the price paid for life. For the successful study of medicine work is essential, and the logical conclusion is that to serve up knowledge to a student in a predigested state must paralyse his effort; mental dyspepsia must be the result. Teaching—or rather cramming—in which the facts of subject are presented to the student without any explanation how the knowledge has been gained only attracts those devoid of ambition, whose only desire is to qualify and make a living. The process is fatal to the evolution of intellectual faculties, and teachers guilty of it are sinning against posterity. The easier it is to get anything the less the desire exists for its attainment, and to make the acquirement of knowledge easy is, perhaps, the best way to increase ignorance. Free education is not the boon it is supposed to be, and compulsory education is impossible and worse than useless. The individual being taught must be an active and willing agent, and all medical study, therefore, should be active, not passive. Most small lectures should be relegated to the dust-heap, though occasional lectures should be given as a stimulus by a master in the subject. A student should attend the courses prescribed regularly and try to gain a clear knowledge of the subject in hand; he comes to a medical school to become an efficiently trained medical man, not to pass examinations.

Work must be purposive and regular if definite results are to be gained. It is foolish to become exhausted by memorising a book so that when an examiner touches the button the record may be produced with painful accuracy. This kind of work is slavery. As a contrast, for instance, there is the student who carefully models freehand the parts of his dissection, building them up to form a solid representation. After an hour's work he deliberately destroys his model, puts the original away, and again attempts to model in freehand. A few days later he tries to model the same part without the original in front of him. He is slowly developing a solid, concrete, stereoscopic X ray image of the human body, which in time will become permanent, and, like his shadow, accompany him everywhere. In the wards and later in his consulting-room it is beside him, at once becoming visible at his command. Diagnosis becomes a simple matter, for thoroughness of work has led to the result aimed at—a full appreciation of the structure and working of healthy and diseased bodies.

It would appear, from which is often said, that when the student reaches his final years of study he is devoid of all or most of the knowledge he has gained in previous years; but obviously he must have learnt something. The truth seems to be that the young fledgeling from a medical school has some knowledge of every subject, but it is not coördinated. He has not been taught in each succeeding stage of his education to make use of the knowledge already gained in the school. Although, of course, any problem in any subject is useful as a mental exercise, and, if overcome, develops the logical faculties and scientific sense, there are problems in medicine so diverse and numerous that it is quite unnecessary and unwise for a student to wander into other fields of knowledge to exercise these faculties. His time is better taken up in coördinating his medical knowledge. The best way to get coördination in knowledge is to prolong the early education into the succeeding

years and to begin the hospital work almost as soon as the student enters the school. Each stage in the education of a medical student should interlock or dovetail with the previous and succeeding stages.

Knowledge should be based on great general principles and students should learn to reason from principles to the special study in hand. A student should not make the mistake of reasoning from the special to the general. He should refrain from depending on his memory. The medical man is a thinking animal, and the practice of medicine depends upon the application of great general principles based upon observation, experience, and research. The sooner a student is set free from his teachers so as to allow experience to be his sole teacher the better for the growth of his real knowledge. Unfortunately, for evident reasons, it is extremely difficult, or almost impossible, to let a student have a direct experience in the treatment of diseases previous to qualification, and it is evident, therefore, that study and work are essential after medical birth and should continue throughout life.

Lack of coördination in the various stages of the student's training is in part due to the fact that the subjects are taught by men who have little experience of the work of later years. This refers to every stage of the student's career, not excepting the final year, for how many clinical teachers in hospitals have any experience of general practice? How many of them are acquainted with the early phenomena of disease by first-hand experience? But are the clinicians not training men to perform duties as general practitioners?—duties of which many are more or less ignorant. Would it be too much to demand that every teacher in a medical school should start life as a general practitioner? Should a general practitioner, an ordinary doctor, not be a member of the staff of every teaching hospital?

Should ordinary catarrhal conditions in children be passed by as of little account whilst rare and incurable diseases, such as acromegaly, are carefully and minutely studied? Is it not better for the future of national health that a student should be thoroughly taught how to recognise and treat a suppurating finger or a common cold, or should a prospective medical man have no knowledge of these mild ailments? Should much of his time be taken up watching from a distance obscure and difficult operations which can only be undertaken by highly trained specialists?

Surely the medical student ought to work for a sound knowledge of the very earliest signs of the disease in addition to studying the pronounced cases which are so common in all hospitals. No attempt should be made at specialism until after graduation. To become a specialist appears to be easy, but gaining the experience and knowledge necessary to be a great doctor is only possible to a few men.

Patients wisely avoid the young doctor, for they do not want to be experimented on. He has thus little chance of studying disease in private. He may deplore that he has chosen so precarious a means of earning a livelihood. He has his chance now, if he will only take it. Let him become a keen student of disease. He should practically live in the hospitals, for he cannot afford to wait for cases at home. Let him realise that he is far from being an expert; let him set about gaining experience. A medical man's first and principal interest should be his profession. Every moment of time can be occupied during this stage in studying cases, working for higher examinations, and becoming expert in the technique of medicine, surgery, and midwifery.

A young practitioner should look forward to a hard life with little remuneration. He will steadily but slowly improve in efficiency and he may add a little to medical knowledge. The practical doctor has greater opportunities to carry on investigations bearing directly on the treatment of disease than the laboratory worker. Prolonged, persistent work gives results, and large unexplored fields are open to all; if the harvest is to be made there must be no strikers, no idlers, no dole-receivers in the profession. Work must be constant. A man simply out to make a living in medicine had better change his occupation and make room for a worker.

It must be clear to anyone with experience that to obtain anything a struggle is necessary, that resistance must be overcome, that work must be done. In other words, it is true that "Ex nihilo nihil fit"—that out of nothing comes nothing.

THE ROUS SARCOMA No. 1.

AN EXPERIMENTAL STUDY.

By RONALD D. MACKENZIE, M.B., M.R.C.P. EDIN.,
LECTURER IN PATHOLOGY, UNIVERSITY OF EDINBURGH;
AND
C. F. W. ILLINGWORTH, M.B., F.R.C.S. EDIN.,
CLINICAL TUTOR AND SENIOR CLINICAL ASSISTANT, ROYAL INFIRMARY, EDINBURGH; PART-TIME RESEARCH WORKER UNDER THE MEDICAL RESEARCH COUNCIL.

(From the Departments of Experimental Surgery and Pathology, University of Edinburgh.)

IT has recently been claimed by Gye[1] that the infectivity of the cell-free filtrate of the Rous chicken sarcoma is due to the presence of two factors: firstly, an ultra-microscopic particulate body capable of cultivation, and therefore presumably organismal—the "virus"; and, secondly, a labile substance, possibly chemical in nature, believed to be derived from the tissues of the host. These two substances, although individually inert, are capable in combination of inducing Rous tumour formation.

Gye has further claimed that a principle apparently identical with the supposed "virus" is present in certain mammalian tumours and that it can replace that of the Rous tumour, or, in other words, can activate the Rous chemical factor.

The chemical factor, on the other hand, is probably different for each type of tumour and for every species of animal, and it is this fraction, the "specific" factor, which determines the nature and site of tumour formation.

The procedure adopted by Gye for the isolation of these two factors is the following:—

A piece of fresh Rous tumour tissue is dropped into a special serum broth culture medium and incubated for 24 hours. The fluid from such a culture is active, and if injected into a suitable chicken it will produce a Rous tumour. To a culture such as this the name "primary culture" has been given. If incubation is carried on for three days or longer the culture becomes inactive, and when injected into a chicken no tumour results. This inactivity is believed to be due to destruction of the specific or chemical factor by prolonged incubation.

If, however, some fresh active fluid, obtained by grinding up a piece of Rous tissue with Ringer's solution and filtering off the gross particles, is treated by the addition of a few drops of chloroform and by incubation for three hours, it is also rendered inactive, due in this case, it is thought, to destruction of the virus.

Although these two fluids are individually inert, when they are mixed together in equal portions and injected into chickens, tumours appear which in every way resemble the Rous sarcoma No. 1.

Cultures similarly prepared from certain mammalian tumours—viz., mouse carcinoma 63, Jensen rat sarcoma, and rat carcinoma 9, are also used to activate Rous chloroformed filtrate. Gye has also been able to "subculture" the "virus" in a serum broth medium to which chick embryo has been added, the fluid even of an eighth subculture being able to activate chloroformed filtrate.

Almost immediately following the publication of Gye's paper suggestions were put forward by Twort[2] and others that it might be possible to activate Rous chloroformed filtrate (i.e., chemical or specific factor) by agents obtained from non-neoplastic tissues, and such substances as embryo tissue and autolysed tissue have been suggested.

In the investigations described below we have endeavoured, in the first place, to repeat Gye's

experiments in confirmation of the presence of two essential factors in the production of a Rous chicken sarcoma. In the second place we have attempted to determine whether one of these factors, the "virus," can be replaced by agents derived from other malignant growths and from benign tissues. Thirdly, we have attempted the artificial cultivation of the "virus."

Practical and Technical Notes.

In order to avoid unnecessary repetition we shall detail here certain materials and methods used by us throughout this work.

Culture Media.—Hartley's broth, as modified by Gye, was used throughout. Serum was obtained from rabbits by cardiac puncture and added shortly before use. We were rarely troubled with sepsis in the media.

Anaerobiosis.—The McIntosh and Fildes jar was used to secure strict anaerobic conditions and gave very satisfactory results. Air was removed by a Geryk pump, and the degree of anaerobiosis was checked by means of a methylene-blue indicator.

Filtration.—Chamberland filter candles L_1 and L_2 were used in various experiments. L_1 passes many small organisms easily. L_2 is of finer mesh and prevents the passage of *B. prodigiosus*. Suction by means of a small water-pump was used in connexion with these filters. All candles were carefully examined before being used.

Sand-and-paper pulp filters were made up and used as described in detail by Gye and Andrews.[3] "Sand filtrate," obtained by passing a Rous tumour emulsion through such a filter, is a clear, slightly yellow fluid capable of tumour production when injected in very small doses.

Chickens.—Only Barred Plymouth Rock chickens were used. Generally they were about one month old. All the chickens used in any one experiment were of about the same age and size.

Removal of Tumour.—The birds were killed by coal-gas, plucked, and then placed in a solution of weak lysol for five minutes. After this the skin was incised and reflected by means of a cautery. It was then an easy matter to remove the tumour aseptically, and except in our very earliest experiments we were never troubled by sepsis to any extent.

Concealed Contamination.—To begin with, we made a practice of putting up cultures in broth and on agar from all our primary tumour cultures for both aerobic and anaerobic incubation, but we soon found that this was unnecessary and that it was generally quite an easy matter to identify a contaminated culture after the long incubation necessary in these experiments. If the contamination was so well concealed that it did not appear during incubation for three to 12 days, its presence seemed to us to be of little importance. We may add that in some of our earliest experiments, when sepsis was present, it did not appear in any way to interfere with the activity of the "Rous agent."

Silica.—Following the practice of Rous and of Gye we have added a trace of silica to all our fluid injections.

Experiments to Confirm that Two Factors Exist in Infective Fluid.

It was necessary first to attempt to ascertain if Rous infective fluid contained two factors, individually inert but active when in combination. The most important evidence put forward by Gye in this connexion is illustrated by his experiment dated Jan. 14th, 1924. In this experiment he shows that by adding a Rous "primary culture" rendered inert by prolonged incubation to a filtrate inactivated by chloroform a potent mixture is obtained which produces typical sarcomata when injected into chickens.

We have performed a considerable number of experiments in an attempt to confirm this fundamental finding, altogether over 120 fowls being thus inoculated. Three experiments are described in detail below. They have been selected because they represent the various types of results that we have obtained. For convenience they have been renumbered 1, 2, 3.

Expt. 1.—A fragment of Rous tumour about the size of a split pea was incubated aerobically in rabbit serum K.Cl. broth in an Erlenmeyer flask for four days. At the end of this period the supernatant fluid was filtered through an L_2 Chamberland candle. Fresh active fluid was obtained by grinding up a piece of Rous tumour and diluting it with Ringer's solution. This fluid was filtered through sand-and-paper pulp, and lastly through an L_2 candle. Part of this L_2 filtrate was used in the fresh untreated condition, the remainder being subjected to chloroform as described by Gye. Chickens were then inoculated as indicated in Table I. which also shows the appearance and relative size of the resulting tumours.

This experiment confirms in every way the results obtained by Gye. It will be seen that a four-day primary culture of Rous tumour was inactive, as was also a fresh chloroformed filtrate, and that the two, when combined, were very active and produced Rous tumours which killed in 21 and 23 days. It is of interest

TABLE I.

Chick.	Inoculum.	Day. 7	18	23	26	32	40	50
74	4-day culture 1 c.cm.	–	–	–	–	–	–	–
75	Chlor. filtrate 1 c.cm.	–	–	–	–	–	–	–
76	Culture plus chlor. filtrate 0·5 c.cm. each.	–	–	+ (*a*)				
77	Do.	–	+ + + (*b*)					
78	Untreated L_2 filtrate 1 c.cm.	–	–	–	+	+ + + (*c*)		

(*a*) Died 23rd day. (*b*) Died 21st day. (*c*) Died 37th day.

to note that the tumours produced by this mixture appeared earlier and grew more rapidly than that produced by a plain untreated L_2 filtrate—possibly an indication of variation in the resistance of individual birds to tumour growth, a factor which we believe to be very important and to be the cause of much difficulty in the interpretation of experiments of this nature.

Expt. 2.—Fragments of Rous tumour were incubated aerobically in R.S.K.Cl. broth for seven days, at the end of which time the supernatant fluid was filtered through an L_1 candle. "Sand filtrate" of fresh tumour was obtained and subjected to chloroform. Chickens were then inoculated as shown in Table II.

TABLE II.

Chick.	Inoculum.	Day. 8	15	20	26	38	45	60
114	7-day culture 1 c.cm.	–	–	? (*a*)				
115	Do.	–	?	+	+ + (*b*)			
116	Chlor. filtrate 1 c.cm.	–	–	–	–	–	–	–
117	Do.	–	–	–	–	–	–	–
118	Culture plus filtrate 0·5 c.cm. each	–	+ + (*c*)					
119	Do.	–	+ + (*c*)					

(*a*) Died 25th day; small tumour. (*b*) Died 26th day; large tumour. (*c*) Both died 19th day; large tumours.

Unfortunately all our experiments did not work out as satisfactorily as Expt. 1. The chief difficulty which we encountered was the persistent activity of the primary cultures. To obviate this we extended the period of incubation to five, six, or seven days, and even then the cultures remained active when injected by themselves. This is well illustrated in Expt. 2 (Table II.). Chicks 114 and 115 both received an injection of 1 c.cm. of a seven-day culture and developed tumours which appeared on the 20th and 15th days respectively. Even here, however, there is evidence of the presence of two factors. It has been shown that with Rous tumour filtrates the size and rapidity of growth of the tumour bears a somewhat direct proportion to the amount of active fluid injected. Chicks 118 and 119 received half the dose of active culture as compared with the control birds Nos. 114 and 115, yet they developed tumours which appeared earlier and grew more rapidly. The proof of the presence of two factors in this experiment is less obvious than in Expt. 1, owing to the persistent activity of the cultures as seen in chicks 114 and 115.

Expt. 3.—Fragments of Rous tumour were incubated aerobically in R.S.K.Cl. broth for 12 days. No contamination occurred. At the end of this time the supernatant fluid was passed through an L_1 filter. Active 24-hour primary culture of Rous tumour was filtered through an

L_1 candle and then subjected to chloroform. Chickens were inoculated as shown in Table III.

TABLE III.

Chick.	Inoculum.	Day. 8	12	19	25	51
195	24-hour culture chlor. 1 c.cm.	—	—	—	—	—
196	Do.	—	—	—	—	—
197	12-day culture 1 c.cm.	—	—	—	—	—
198	Do.	—	—	—	—	—
201	Chlor. culture plus 12-day culture 0·5 c.cm. each.	—	—	—	—	—
202	Do.	—	?	++	+++ (*a*)	
205	Chlor. culture plus M.63 culture 0·5 c.cm. each.	—	—	(?)	+	
206	Do.	—	—	+	+++ (*c*)	

(*a*) Died 27th day. (*b*) Died 30th day. (*c*) Died 26th day.

To overcome the difficulty illustrated in Table II. we have used increasingly long periods of incubation to obtain an inactive primary culture. The result obtained with a 12-day culture amply justifies this procedure. It will be noted that in this case the "specific factor" was obtained by chloroforming an active 24-hour culture filtered through an L_1 candle in place of the usual sand filtrate, largely a matter of convenience, as any active cell-free fluid, however obtained, should serve.

This experiment, which completely bears out Gye's hypothesis, is described in full to illustrate (1) that even after 12 days' incubation the "virus" would appear to be present unimpaired, and (2) that any technical difficulty found in the making and use of "sand-filters" may be avoided by employing an active 24-hour culture as a source of "specific factor." Chick 201 did not develop a tumour, while chick 202, which received a similar injection, died on the 27th day with a large growth in the pectoral region. This difference we believe to be due to a variation in the resistance of particular birds to tumour growth. Chicks 205 and 206 are referred to later.

Discussion.

Our chief pitfall in performing these experiments has been the prolonged activity of primary cultures, which appears to have been increasing during the past few months and to be related to a gradually increasing virulence of the tumour strain. Thus in our earlier experiments, as illustrated in Table I., three- and four-day cultures sometimes proved inert, whereas now even a seven-day culture may be active by itself (Table II.). Correspondingly, tumour transplants have exhibited an increasing tendency to widespread metastasis-formation and to early destruction of the host. This is to be compared with the experience of Gye and Andrews,[3] whose tumour strain passed into the opposite phase.

On the other hand, the chloroformed filtrate has, in our experience, been almost invariably inactive, only one chick out of a considerable number which received 1, 2, or even 4 c.cm. of the chloroformed filtrate developing a tumour, which appeared as a small nodule two months after the injection. This differs greatly from the results obtained by Harkins, Schamberg, and Kolmer,[4] and it would seem possible that they are right in attributing their faulty inactivation to the particular grade of chloroform used. Throughout our experiments Messrs. Macfarlan and Co.'s chloroform (acetone prepared) has been employed. It is stored in the laboratory exposed to light and therefore probably contains toxic decomposition products which may be responsible for the inactivation previously attributed to the chloroform itself. It is interesting to compare the results of these workers with those of Murphy,[5] who has at no time had difficulty in rendering a filtrate inactive by chloroform.

Our general conclusion from this series of investigations is, therefore, that it lends considerable support to the belief that the Rous tumour arises from the conjunction of two factors. One of these may survive incubation in serum broth for 12 days, but is readily destroyed by chloroform; the other survives exposure to chloroform, but is rendered inert by prolonged incubation.

ACTIVATION OF ROUS CHEMICAL FACTOR BY AN AGENT OBTAINED FROM MAMMALIAN TUMOURS.

Gye has also been able to activate the Rous "specific factor" by agents derived from certain mammalian tumours—a mouse carcinoma, two rat tumours, and a human adenocarcinoma of the breast—and from these observations he draws the general inference that the "virus" is common, at any rate, to many malignant neoplasms.

An attempt was made to repeat these experiments, making use of two mouse tumours, M.63 and 37/S of the Imperial Cancer Research Fund, as our source of "virus." We attempted to follow as closely as possible the method employed by Gye, namely:—

The mammalian tumour was removed aseptically and a fragment was dropped into some Hartley's serum broth and incubated anaerobically for three days. The fluid from the culture was then removed and mixed with an equal amount of chloroformed filtrate of a Rous tumour emulsion. The mixture was injected into Plymouth Rock chickens. Control injections of the chloroformed filtrate alone were always made.

Working with mouse sarcoma 37 we were never successful in activating Rous chloroformed filtrate by the addition of cultures of this tumour. With M.63 we had at first only negative results, but just recently we succeeded in activating a chloroformed Rous culture by the addition of a three-day anaerobic culture of this mouse carcinoma. This is illustrated in Table III., chicks 205 and 206. These are the only two positive results out of 27 chicks thus inoculated. We ascertained later that Gye [6] has never succeeded in activating the chloroformed filtrate by the addition of a culture of 37/S, although he has had frequent successes with M.63.

Murphy claims to have substituted an agent obtained from another chicken tumour and to have succeeded in activating the inert chloroformed filtrate by this means, and thus in part to have confirmed some of Gye's work, although his interpretation of the result is different.

CULTIVATION OF THE VIRUS.

It has been shown by Gye that when a loopful of fluid from an active primary culture of Rous tumour is transferred to a fresh tube of serum broth medium containing a piece of chick embryo the fluid in this "subculture" becomes potent and is able to activate chloroformed filtrate. This is taken by him to indicate life of the virus, more especially since he has been able to carry on this process of subculturing as many as eight times, the eighth subculture being as potent as the first primary culture in its power to activate chloroformed filtrate.

Chicken embryos of from 8 to 16 days' incubation have been used. They are taken aseptically from the shell immediately after its removal from the incubator and placed in R.S.K.Cl. broth in a McIntosh and Fildes jar. To each culture-tube containing embryo serum broth a loopful of an active "primary culture" was added. This "subculture" was then incubated for three to four days. Equal parts of the fluid from this subculture and of inert chloroformed filtrate were then mixed and injected into chickens in doses of 1 c.cm.

We were never successful in activating inert chloroformed filtrate by the addition of subcultures of virus (Table IV.).

ACTIVATION OF ROUS CHEMICAL FACTOR BY AGENTS OF NON-MALIGNANT ORIGIN.

The fact that the medium for a successful subculture must contain chicken embryo has suggested to many the possibility that embryonic tissues themselves may have the power of activation of Rous chemical factor, and thus it is suggested that Gye is in reality dealing

with a growth factor which is not necessarily confined to malignant neoplasms.

The influence of embryonic tissue extracts in promoting the growth of cells in vitro is well established. Somewhat similar factors are said to be found in tissues undergoing autolysis, and it was therefore thought possible that these substances might be capable of activating the Rous chemical factor.

The question of the activation of Rous chemical factor by embryonic tissues has been studied by Gye,[7] who reports that he has tried to replace the "virus" by chicken embryo cultures on 150 occasions without success. This is especially interesting because Murphy [5] has recently shown that he is able to activate the chemical factor by the addition of cultures of chick embryo, rat placenta, and mouse placenta. The discrepancy in the results of these two well-known workers has suggested to Chambers [8] that there is probably some small difference in the technique employed. In her opinion the activating factor may be a product of autolysis, probably chemical in nature, and she further states that such substances have been found in cultures grown under the conditions described by Gye.

In order to test this assumption various products of autolysis were added to Rous treated filtrate. In similar experiments anaerobic cultures of chick embryo, mouse embryo, and mouse placenta have been used. The chief experimental details are as under:—

Chicken embryos were obtained as before and cultured anaerobically for three to four days in serum K.Cl. broth.

Mouse embryo and mouse placenta of varying periods of gestation have been cultured in the same way.

To obtain "growth-promoting" factors under conditions which will exclude the possibility of organismal growth, fragments of Rous tumour and of M.63 tumour have been autolysed at 37° C. in Ringer's solution, to which toluene has been added in the manner described by Chambers and Scott.[9]

Fluids obtained from these different sources have been mixed with chloroformed Rous filtrate and injected into chickens. The total number of these experiments is given in Table IV. On many of the occasions on which non-malignant agents were inoculated experiments similar to our Experiments 1, 2, and 3 were performed, using portions of the same chloroformed filtrate, the activity of which was thus observed.

TABLE IV.

Inoculum (dose 1 c.cm.).	Total No. of chicks inoculated.
Chloroformed filtrate plus "subculture" of "virus"	17
Chlor. filtrate plus chick embryo culture	19
" " mouse embryo "	9
" " mouse placenta culture	11
" " Rous autolytic fluid	7
" " M.63 " "	5

(No tumours resulted in any of the above experiments.)

It will be seen that in all cases in which we attempted the activation of the treated filtrate by the addition of subcultures of "virus," cultures of embryo tissue and of autolysed tissue, we have up till the present obtained only negative results.

MAMMALIAN TUMOURS.

Included in Gye's original paper there is a short but important section dealing exclusively with mammalian tumours and in particular with mouse sarcoma 37.

Many attempts have been made in the past to transmit mammalian tumours by a cell-free filtrate and thus to bring them into line with the Rous tumour. Discussing this matter with regard to 37/S, Gye says that it may be taken for granted that this is not a filter-passing tumour in the same way that the Rous tumour is. He has found, however, that if a piece of this tumour is incubated anaerobically in serum K.Cl. broth for 24 hours, the supernatant fluid, removed and filtered through an L_1 candle, when injected into mice, will produce tumours in a large percentage of cases in about 14 days. These tumours are believed to arise from the cells of the host, which, owing to the action of the injected virus, have become malignant. Gye adds, in further proof that the fluid is cell-free, that tumour cells undergo a fairly rapid necrosis when incubated under anaerobic conditions, and quotes an experiment in which incubation for even 18 hours in Ringer's solution was sufficient to kill off all the tumour cells.

In our earliest experiments we adopted the method described by Gye, using a 24-hour anaerobic culture of 37/S. We injected altogether about 80 mice from a large number of different cultures, but we never succeeded in obtaining a single positive result. Later we modified our technique, and instead of using a plain 24-hour culture we made use of a mixture of equal parts of a three-day culture, presumably rich in virus, and a 24-hour culture relatively rich in chemical factor. We also tried a mixture of a three-day anaerobic culture of mouse carcinoma 63- and 24-hour culture of 37/S. In all these modifications, as in the original experiment, we were unsuccessful and no tumours resulted.

While performing these experiments we also tested the power of survival of tumour cells when incubated anaerobically in serum broth, and we found that in the case of tumour 37/S the cells survived as long as three days, and when transplanted into mice produced tumours in the usual way. Carcinoma 63, however, only survived about 24 hours. This result is very similar to that obtained by Okamoto [10] working with certain other mammalian tumours, and indicates the importance of adequate filtration of the cultures.

SUMMARY.

Some of the experiments described by Gye in relation to the Rous chicken sarcoma and other neoplasms have been repeated. The behaviour of certain non-malignant tissues under similar experimental conditions has also been observed. The following conclusions have been reached:—

1. Experimental results are recorded which largely tend to confirm the presence in Rous sarcoma fluid of two causal factors which, individually inert, in combination give rise to tumour growth. One of these factors, the "virus," will survive prolonged incubation, but readily succumbs to exposure to chloroform. The other, the "specific factor," is little affected by chloroform, but is rendered inert after a period of incubation depending upon the activity of the particular strain of tumour used.

2. The "virus" of the Rous tumour has been replaced, in a small proportion of experiments, by an agent derived from a mammalian tumour (mouse carcinoma 63).

3. We have been unable to replace the "virus" by agents derived from mouse sarcoma 37, certain embryonic or placental tissues, or by "growth-promoting factors" in autolytic fluids.

4. We have been unable to "subculture" the "virus."

5. Our experiments throw little light upon the nature of the two factors involved. The terms "virus" and "specific factor" are used for convenience only.

6. We have been unable to transmit mouse sarcoma 37 by injections of a cell-free culture fluid.

7. Incidentally it has been shown that the malignant cells of 37/S may remain alive under strictly anaerobic conditions for as long as three days.

8. Variation in the susceptibility of individual animals to tumour growth constitutes a factor which must be taken into consideration in the interpretation of experiments of this nature.

This work must only be considered as a preliminary to a further and more extensive study of the Rous tumour and its relationship to tissues simple and malignant.

In conclusion, we should like to thank all those who have so kindly helped us in the carrying out of this work. Especially we would gratefully acknowledge our indebtedness to Prof. D. P. D. Wilkie for the great personal interest which he has taken in this research and for the facilities for work which he has so unreservedly placed at our disposal in the newly-equipped department of experimental surgery. We

are indebted to Prof. J. Lorrain Smith, F.R.S., and Prof. T. J. Mackie for the help and encouragement which they have given us. Our thanks are also due to Dr. W. E. Gye, who has personally demonstrated to us the more important points of his technique, and supplied us with a strain of the Rous tumour, and to Dr. Thomas Lumsden, of the Lister Institute, who first instructed us in the management of transplantable tumours.

The mouse tumours used in this work were obtained by courtesy of the Imperial Cancer Research Fund.

Our expenses in connexion with this work have been met partly by a grant from the Earl of Moray Research Fund of the University of Edinburgh, and partly by a special grant obtained from the British Empire Cancer Campaign.

SOME POINTS IN THE SURGICAL MANAGEMENT OF SEMINAL VESICULITIS.*

BY A. REITH FRASER, M.D. ABERD.,
LECTURER IN VENEREAL DISEASES, UNIVERSITY OF CAPE TOWN;
AND
L. B. GOLDSCHMIDT, M.B., B.S. LOND., F.R.C.S. ENG.,
ADDITIONAL SURGEON, NEW SOMERSET HOSPITAL, CAPE TOWN.

IT is probable that no part of the urogenital system in the male is so neglected as the seminal vesicles, and yet they are implicated much more frequently than is generally supposed. Their natural defence is very poor; they are tortuous cul-de-sacs with blind diverticula lined by columnar epithelium, the whole arrangement lending itself ideally to the harbouring of infection. Moreover, the only route of natural drainage is via the ejaculatory ducts, which open into the deep urethra, itself a frequently infected cavity with none too effective drainage.

Classification.

The classification of seminal vesiculitis is at best empirical. Four clinical types may be recognised: (1) Infected, (2) hæmatogenous, (3) obstructive, (4) traumatic.

1. *Infected Vesiculitis.*—This group includes such cases as those occurring in a spreading gonorrhœa, the local spread, either direct or indirect, of a *B. coli* or pyogenic infection of the urinary tract. Infections such as bilharzia and actinomycosis are also included in this group.

2. *Hæmatogenous Vesiculitis.*—Many types of infection, such as syphilitic or tuberculous, reach the vesicle via the blood stream, as do also infections from obvious septic foci in teeth, tonsils, or alimentary tract.

3. *Obstructive Vesiculitis.*—In this group are included cases where the poor drainage of the vesicle is further interfered with by such mechanical factors as changes in the prostate consequent on adenomatous or carcinomatous conditions. The ejaculatory duct is either pressed on or deviated, and the vesicular secretions dammed back, resulting in an irritative inflammatory condition of the vesicle. Infection may be superimposed.

Masturbation is responsible for a form of vesiculitis which may be included in this group. The habit produces a condition of complete atonicity of the vesicle accompanied by a local congestion of the prostate, which increases the difficulty of the vesicular discharge in finding its way out, and the atonic vesicles are entirely unable to surmount it. Congenital anomalies may also give rise to a vesiculitis of the obstructive type. Obstructions, such as inflammatory stricture of the duct, are not included in this group.

4. *Traumatic Vesiculitis.*—Trauma directly applied to the vesicle is the prime cause of a number of cases of inflammation. Ill-applied massage is the commonest. Rough treatment by the rectal finger, in the course of a suprapubic prostatectomy, is frequently the origin of a post-operative vesicular flare-up.

Clinical Picture.

By far the commonest infection of the seminal vesicles is extension of gonococcal inflammation, and to such cases, therefore, our subsequent remarks will be confined. In acute vesiculitis the symptoms may vary within wide limits. There may be straining and painful urination, often amounting to vesical tenesmus; constant shooting pains in the perineum, epigastrium, rectum, and anus; direct and referred pains on urination and defæcation; retention of urine; vomiting; tympany; constipation; abdominal tenderness; persistent erections and painful blood-stained emissions. Such a picture is accompanied by a hot, tender, fluctuating vesicle, swollen and enlarged, and bulging ominously in the entire space immediately above the prostate. On the other hand, the vesicles may be involved in the course of an acute gonorrhœa with no local symptoms, and the examining rectal finger may fail to detect the parenchymatous changes in the gland.

It has been said that vesiculitis is always bilateral, but in our experience it was not rare to find gross vesiculitis in one vesicle, while the other vesicle had a normal exudate, was normal to rectal touch, and gave a ventriculogram which, in contrast with its fellow, showed no radiographic evidence of disease.

The clinical picture of chronic vesiculitis is equally varied. There may be no symptoms, so that the implication of the vesicles is only discovered as the result of a precipitate joint attack, an unresolving iritis, a phlebitis of the internal saphenous vein, or merely a routine rectal examination. On the other hand, a patient may suffer from a recurring gleet, a recurring epididymitis, irregular bouts of urgent urination, indefinite pains in the lumbar region, flanks, and thighs; alteration in sexual powers and sensations, aching pain in the testicles, or pronounced symptoms of sexual neurasthenia. It is well known that the gonococcus may live unsuspected in the vesicles for many years, and then may suddenly acquire new virulence and assume pathological importance. Iritis in men over 50 is not infrequently due to a gonorrhœa of some 20 or 30 years before. The significance of the vesicles is well known as the focus of infection in gonorrhœal arthritis.

The symptomatology may be that of a kidney or bladder lesion and only on full investigation is the vesicle found responsible. The ureter, for example, may be involved in the infiltration of a perivesiculitis, and kidney changes ensue.

The normal vesicle is impalpable unless greatly distended. The acute condition accompanied by a hot, exquisitely tender, swollen, fluctuating vesicle is straightforward, but the chronically infected vesicle, with its infiltrated walls matted together in a perivesiculitis, without accompanying swelling, sclerosis or pain, is often extremely difficult to define by rectal palpation. Should secretion be obtainable, it is found to contain pus and bacteria. Frequently, however, the inflamed vesicle is not draining and secretion cannot be obtained. Even under such circumstances no great swelling of the gland can be made out per rectum.

It may happen that an acute vesiculitis exists while the urine in all three glasses is clear and free from pus or other débris. Kidd describes a dull thin haze of pus, of a peculiar and characteristic appearance, as diagnostic of vesiculitis, but we have found interpretation of the urine very much more difficult.

* A paper read before the Twentieth South African Medical Congress. Since its delivery we have had to chronicle the death of Dr. Reith Fraser.

Indeed, the urines of two cases of vesiculitis are very seldom alike. Much depends on the state of the urethra and prostate. If these are not implicated, and the vesicles are not draining, the urine is invariably clear. Indeed, gonococci have frequently been recovered from the vesicles of men suffering from iritis, who have passed clear urines for over 30 years. In these cases diagnosis can only be made by rectal palpation of the vesicles, combined with bacteriological examination of the secretion.

Vesicular Massage.

Many writers are enthusiastic about the efficiency of vesicular and prostatic massage, while others regard it as of little use, although, conservatively, it is the best method at our disposal. Keyes tells us that "a constipated movement of the bowels will often squeeze out more semen from a boggy prostate than any finger can. A seminal emission is never so small as the few drops extruded by massage. Yet, for the period between the subsidence of acute gonorrhœa and the return to cohabitation, massage is the best alleviation we have to offer for the treatment of chronic prostatitis and vesiculitis."

It must be recognised that an emission during acute vesiculitis is a deleterious trauma, while in the chronic state the resumption of normal sexual function is the basis of cure. Indeed, as Keyes remarks, "sexual starvation or gluttony is as bad for the chronically inflamed sexual organs as constipation and gluttony are for the chronically inflamed digestive organs." Unskilled and indiscriminate massage certainly does little good. Massage is an intelligent manœuvre and must be carried out intelligently, with due regard to the pathological condition. It is idle and frequently harmful to massage blindly until either the finger or the patient tires. The object of massage is to improve the circulation of the parts, increase the muscular tone and, as far as possible, secure free drainage. Thus certain cases require severe massage, while in others only the mildest manipulation is sufficient. Nor must it be forgotten that vigorous massage on occasion may precipitate an acute vesiculitis, prostatitis, or epididymitis.

There is a very large percentage of cases, however, which fail utterly to respond to such conservative methods. It is true that many are benefited in the most astonishing manner by the administration of three or four doses of normal horse serum, some foreign protein such as aolan or casein, or intravenous sulfarsenol, but a large number still remain unresolved. Hot rectal douching, diathermy, urethrovesical irrigation, accompanied by urethral dilatation and the removal of any urethral focus, have been employed pari passu with vesicular massage without avail. The percentage of such cases is very high indeed.

Catheterisation of the Ejaculatory Ducts.

One other conservative attempt to secure drainage of the vesicles made by urologists is catheterisation of the ejaculatory ducts. Urethrovesical irrigations and dilatation of the deep urethra are first carried out until a large urethroscope tube can be introduced without trauma. Under local applications the veru rids itself of its pathological products. When this stage is reached the prostatic utricle and ejaculatory ducts are explored. Luys maintains that catheterisation of these canals is necessary in the majority of instances and absolutely indispensable in many.

This difficult procedure has also been carried out by Young, of Baltimore. Kidd, however, states that it is not possible to catheterise these ducts except in a few cases. McDonagh is equally emphatic, concluding: "I have yet to see a case in which such a procedure has been successful." Our own experience has been that in a urethra of more or less normal anatomy it is not unduly difficult to persuade a Young's double tube to enter the orifices of the ejaculatory ducts; but to inject medicament is another matter, as it regurgitates into the urethra and none enters the vesicle. Endeavours to persuade the catheter farther along the duct have invariably terminated in traumatism. In a pathological urethra we have frequently failed to locate the ducts with sufficient accuracy even to allow of an attempt at catheterisation.

Diathermy.

Cumberbatch and Robinson have described their methods of dealing with seminal vesiculitis by means of diathermy, and are satisfied that the "treatment possesses therapeutic value in cases of gonococcal prostatitis and vesiculitis," but it is extremely doubtful if diathermy alone will cure vesiculitis. As an adjunct to other measures, however, it is a line of conservative management of undoubted value.

Vasotomy and Vasostomy.

The operation of vasostomy, first advocated by Belfield, has proved a distinct advance in the treatment of seminal vesiculitis, and the principle of applying medication to the vesicle via the vas has found a definite place in the treatment of these structures.

The operation consists essentially of :—

1. By means of digital manipulation through the shaved and purified skin of the scrotum, the vas is separated from the remaining structures of the cord and fixed by means of a transfixing needle on the scrotal side of the penoscrotal angle.
2. An incision of 1 cm. is then made with a sharp scalpel, directly over the vas thus fixed, and the vas lifted free from its connective tissue coverings.
3. An incision with a fine-pointed blade is made longitudinally into the stripped vas and the lumen exposed.
4. A blunt-pointed needle is introduced into the lumen and through this the medicament is injected.

The operation can be performed under local anæsthesia without any complaint of vesicular colic, and after a little practice can be completed in from 5–10 minutes. Many modifications of the procedure have been advocated. Some observers report methods of "percutaneous puncture," but we have found it sufficiently difficult to be certain of entering the lumen of the vas when it is fully exposed and clean. Puncture of the vas with a sharp needle, after it has been freed, is less satisfactory than first incising longitudinally. A longitudinal incision makes one absolutely certain of entering the lumen, and a longitudinal slit is less damaging to the vas than a transverse one.

In the early cases of our series, selected for operation on account of the chronicity of the condition, we used the Belfield technique of ligaturing the edges of the vas incision to the edges of the skin to facilitate repeated injections, but local œdema and lymph exudate made it difficult to find the lumen to reintroduce the needle. We tried tying a needle within the vas, passing a strand of fine silkworm-gut along the vas for a distance of 5–6 inches. A needle could be threaded over this and introduced into the vas on the principle of a tunnel bougie. Before withdrawing the needle the gut was replaced through the needle and the needle withdrawn over it and the gut left in. This procedure we still adopt if for any reason we desire to give more than one injection within 48 hours.

In three of our cases where the vas was retained at skin level for repeated injections it could not be returned to the deeper scrotal tissues on account of rigid adhesions, and spermatic fistulæ developed.

In view of these difficulties we tried single large injections of a stronger chemical (25 per cent. argyrol), returning the vas immediately, after washing the chemical through with 1 or 2 c.cm. of saline and closing the wound with a single Michel clip. The injection is made with a 10 c.cm. record syringe, and continued until a definite resistance is felt, or 15 c.cm. have been injected. In some cases the resistance increases and then suddenly gives on slightly increased pressure, and in these we have found by urethral catheter that at the moment of "give" the black argyrol enters the urethra. Where no resistance at

all is felt the argyrol flows through to the urethra almost at once. Where resistance is felt, after, say, 6–10 c.cm. have been injected, no medicament is recovered immediately from the urethra, and in these cases it is our practice to leave the medicament within the vesicle.

In some cases after a varying time the urine shows the drug; if none has appeared in the urine at the end of 48 hours we proceed with gentle vesicular massage, in the course of which the distended vesicle can often be felt to collapse, evacuating its contents.

In these cases it has been easy to appreciate the difference in the effect of vesicular massage, which before operation gave a scanty result, but afterwards succeeded in effecting the evacuation of the vesicular content.

In one case only has there been any suspicion of rupture of the vesicle. In this case definite symptoms of rectal irritation and an indurated mass, palpable per rectum, appeared within 24 hours of operation, but the symptoms subsided after hot rectal douching.

We have found the above procedure of great value in clearing the chronic type of case so graphically described by Kidd, and in the acute case of almost equal value. In every case a course of massage, vaccine, urethral dilatation and instillation, &c., is carried out subsequently.

In a type of case, which must frequently pass as "typhoid," a vasostomy has exaggerated the temperature and toxæmia for 24 hours, and then with the appearance of the argyrol in the urine the temperature has dropped, as it does after the evacuation of pus from an abscess. We employ vasotomy as a routine in epididymitis cases calling for epididymotomy and have observed no tendency to relapse.

In certain cases where we have been able to introduce medicament the vesicle appears to be loculated, so that only the portion in proximity to the ejaculatory duct drains satisfactorily. The rectal feel of such a case is always that of a firm, sclerosed, not much distended vesicle.

Value of Vasostomy.

The most important criticism of vasostomy has been that it tends to cause stricture of the vas and, if bilateral, probably sterility. The objection is not entirely groundless, especially if the vasostomy is kept open over a fairly long period, though there is less tendency to stricture formation than might be imagined, and with our procedure it is to all intents and purposes negligible. The danger of stricture lies mainly in the amount of damage caused to the vas from trauma at operation, subsequent manipulation with the risk of secondary infection, and the damage directly due to the injection of strong chemicals. These causes are minimal with one single injection well washed through and the wound immediately closed. We do not consider it advisable to keep the wound open longer than 48 hours, and if more injections seem indicated we prefer to carry out a second vasotomy.

On reviewing the literature we have been struck by the tendency of certain observers to credit vasostomy with immediate and complete cure. Our own view, however, is to regard the operation as an adjunct of very great value to conservative measures. It initiates resolution and renders conservative manœuvres, previously futile, effective. Its greatest value consists in shortening the length of treatment (probably by 75 per cent.) and in converting a case which will not respond to conservative measures into one that will. The fact that the operation can be performed under local anæsthesia adds greatly to its practical value.

Vesiculotomy and Vesiculectomy.

In contrast with the facility of attacking the vesicle via the vas, direct attack with vesiculotomy or vesiculectomy is an operation of great gravity. The perineal route requires an experienced operator. The goal to be reached is not easy from the anatomical standpoint, and the danger of injuring important structures, particularly the rectum, is very real. However, certain cases demand direct attack; in particular, those with acute inflammatory retention in the vesicle; old-standing sclerotic cases occasioning pain, neurosis, or focal infection; cases of ischio-rectal abscess originating from a ruptured vesicle, and cases where ureteral obstruction has resulted from involvement of the ureter in the sclerotic infiltration of a perivesiculitis.

Vesiculectomy is the operation of choice, and only when actual excision of the vesicle is too difficult is vesiculotomy indicated. Care must be exercised to open the vesicle as completely as possible, to scrape its walls with a sharp spoon, and apply pure carbolic to the curetted area. Occasionally only, in an acute case, where vasotomy has failed, is simple incision of the vesicle required, along the lines of a Squire's vesiculotomy.

Summary of Cases.

This communication is based on a series of 32 cases in which operation has been performed. These have been selected from a consultant practice in which probably a much greater percentage of old-standing infections is met with than in an ordinary venereal clinic. The number operated on is approximately 10 per cent. There were three cases of vesiculectomy, in all of which there was ureteral obstruction, one case of vesiculotomy for acute toxæmia with high fever which vasotomy failed to relieve, and 28 cases of vasostomy or vasotomy.

The four cases of vesiculectomy or vesiculotomy resulted in complete symptomatic cure and the removal of all signs of disease. In the remaining 28 cases the vesicle was attacked via the vas, 24 bilateral and 4 unilateral. Of these 11 were vasostomies receiving more than one injection, while in the remaining 17 vasotomy was performed and a single injection made. There were three cases of spermatic fistulæ, all of which followed a vasostomy. The fistulæ were subsequently closed by releasing the vas and burying it. In one case there was suspicion of vesicular rupture following injection, but resolution eventually took place and no untoward consequences were noted. No other unfavourable complication was noted in this series.

In one acute case the result of vasotomy was dramatic, the temperature falling to normal within 12 hours. In the remainder after-treatment was continued for periods varying from three weeks to twelve months before the patient's urogenital system was pus-free, the average being eight weeks.

Conclusions.

From the foregoing discussion three conclusions may be drawn: (1) Conservative methods in the management of gonococcal vesiculitis still hold a premier place. (2) Vasotomy is a surgical procedure which shortens the duration of treatment without serious risk to the patient, and does not carry the tendency to sterility, spermatic fistula, and scrotal nodulation and infiltration which is associated with vasostomy. (3) In cases where direct attack on the vesicles is called for, vesiculectomy holds a distinct preference to vesiculotomy.

STOCKTON HOSPITAL EXTENSION.—Princess Mary Viscountess Lascelles, on Sept. 23rd, opened the extensions to the Stockton and Thornaby-on-Tees Hospital completed at a cost of £71,000. Sir Frank Brown, who presided, said that it was 64 years since the hospital was founded without endowment of any kind, and it was the boast of Stockton and Thornaby that the hospital had never been in debt—largely owing to the energy and munificence of the Mayor of Stockton, Mr. Leonard Ropner, who had given the final £5000 required besides a previous donation of £10,000. The teachers and school-children, he said, had provided the whole of the cots and beds required for the children's wards, while the builders and operators in the district had built a separate building for the nursing staff.

Clinical and Laboratory Notes.

A CASE OF PERFORATED GASTRIC ULCER WITH APPENDICITIS; OPERATION; RECOVERY

BY CECIL P. G. WAKELEY, F.R.S. EDIN., F.R.C.S. ENG.,
ASSISTANT SURGEON, KING'S COLLEGE HOSPITAL AND BELGRAVE HOSPITAL FOR CHILDREN; CONSULTING SURGEON, MAUDSLEY HOSPITAL.

THE following case is interesting on account of its rarity.

History.—A man, aged 24, first attended the surgical out-patient department at King's College Hospital in September, 1925, complaining of abdominal pain, which had been present on and off for a month before the patient came to hospital. There was no history of vomiting; he was constipated, often having only one action in two or three days. On examination he was seen to be a well-built, muscular man; his teeth were very decayed and there was well-marked oral sepsis. The abdomen moved well on respiration, and the only area where tenderness could be elicited on palpation was over McBurney's point, pressure here causing the patient to feel sick. The appendix was palpable and retrocæcal in position. The case was diagnosed as chronic inflammation of the appendix and his name was taken for admission, and arrangements made for dental treatment before he was admitted to hospital.

The patient was not seen again until five weeks later, when he was admitted to King's College Hospital with acute abdominal pain; temperature 100·2° F., pulse 104, respirations 24. He stated that he had been suddenly seized with pain ten hours before admission, and had vomited several times; the pain had continued without intermission. He looked anxious and worn, in fact he was a typical picture of an acute abdomen. On examination the abdomen was rigid all over, but if anything the rigidity seemed most marked in the right iliac fossa. There was no loss of liver dullness and no pain over the right scapular region. A diagnosis of acute appendicitis was made and the patient was taken to the operation theatre. Under gas and oxygen anæsthesia a definite palpable lump was discovered in the right iliac fossa and the diagnosis seemed certain.

The abdomen was opened through a right paramedian incision. On opening the peritoneal cavity a quantity of sero-purulent fluid escaped. The cæcum and appendix were completely covered by omentum; the appendix was retrocæcal in position, and on removing the covering omentum two large concretions were exposed which had ulcerated through its acutely inflamed walls. Large adherent patches of coagulated lymph were seen on the surface of the appendix. The appendix was removed and its stump invaginated by a purse-string suture. A portion of the acutely inflamed omentum was removed between ligatures. On replacing the omentum within the abdomen a quantity of sero-purulent material with isolated flakes of coagulated lymph escaped from the wound; the upper abdomen was explored with the hand and a hard indurated area was felt at the pylorus. On withdrawing the hand gas was heard to escape. The abdominal incision was lengthened in an upward direction and the stomach explored. A large perforation was seen on the gastric side of the pylorus; the size of the perforation can be judged when it almost admitted the tip of the little finger. There was considerable board-like induration around the perforation, and invagination of the ulcer was impossible. The perforation was plugged with a portion of omentum which was stitched in situ; the condition of the patient did not warrant a gastro-enterostomy being performed. The abdominal incision was closed and a large rubber tube draining the pelvis was inserted into the lower end of the incision. The patient was returned to bed and continuous rectal saline was administered. Recovery was uneventful; the drainage-tube was removed on the fifth day, by which time the patient was having light diet. The wound had completely healed by the tenth day when the stitches were taken out. The patient was discharged from hospital three weeks after his operation and was sent to a convalescent home.

In January, 1926, the patient was examined again; he appeared in good health and the abdominal wound was soundly healed, there being no evidence of a ventral hernia. A barium meal was taken which demonstrated considerable pyloric stenosis, due to the cicatrisation of the ulcer. The patient was advised to come into hospital again and have a gastro-enterostomy performed; this he agreed to do. On Jan. 15th a posterior gastro-enterostomy was performed; the ulcer at the pylorus had healed and the omentum was stretched over it in the form of a web. The pylorus was not occluded by a suture. Recovery was rapid and uneventful, and the patient was discharged on Jan. 30th.

Commentary.

Cases in which two acute abdominal conditions occur at the same time are rare, especially so when the stomach and the vermiform appendix are the organs concerned. Very few cases are to be found in looking through the medical literature, the best recorded cases being those of Sir Watson Cheyne and Wilbe,[1] Warren Low,[2] and Lediard and Sedgwick.[3]

On investigating the pathology more fully, one might expect the two conditions to be more frequently associated, as a diseased appendix is often the indirect cause of ulceration of the stomach. That the vermiform appendix and the pyloric portion of the stomach are in direct lymphatic connexion has been well demonstrated by Braithwaite.[4] There is also a definite venous return to the stomach in cases of chronic inflammation of the appendix where the omentum is adherent; this probably occurs via the epiploic veins directly to the gastric mucosa.

A CASE OF ANILINE POISONING.

BY JOHN INKSTER, M.D. ABERD., M.R.C.P. LOND., D.P.H. OXF.,
HON. PHYSICIAN, NORTH ORMESBY HOSPITAL.

A CASE of poisoning by aniline ($C_6H_5NH_2$) in a boy aged 12 years occurred under the following circumstances.

A lesson in distillation was being given to a chemistry class, aniline being the substance used to demonstrate this process. As the aniline was to be returned to stock after distillation, the master told the boys to be careful that no water was mixed with it. One boy distilled his portion into a wet flask, and when he handed it to the master, the latter said, in a jocular manner, "This is a nice mess. It is not fit to be returned to the bottle. You might as well drink it." This the boy proceeded to do. The master immediately dashed the flask from the boy's hand and made him wash out his mouth. The flask contained less than 2 c.cm. of a mixture of aniline and water, and the master was under the impression that the boy had not swallowed any of it.

The boy carried on at school from 9.45 A.M., the time of the incident, and made no complaint nor did anyone notice anything amiss. At 12.20 he took train to his home and arrived at his station without mishap but collapsed outside at about 12.45, and was carried home. He was then unconscious, the finger-tips were blue and the lips almost black. Oxygen was administered continuously through a funnel from about 1 o'clock and coffee and whisky given frequently from then until 4 o'clock. He vomited repeatedly from 2.30 onwards and at 3 o'clock was roused enough to say that he had taken aniline but immediately relapsed into unconsciousness.

Seen at 10 P.M. he was lying peacefully in bed with his eyes shut. He was very drowsy but could be roused with difficulty when he would open his eyes, but would not answer questions. The skin was a pale lilac colour all over except that the lips, ears, tongue, and the nails of the fingers and toes were of a deep leaden blue. The respirations were slow and very shallow. There was no apparent respiratory distress. The pulse-rate was 120 and the pulse regular and small. There was no dilatation of the heart and no abnormal signs were detected in the lungs. The pupils were widely dilated and reacted very sluggishly to light. There was no injection of the conjunctivæ. There was no paralysis. The tendon reflexes were somewhat diminished.

As it was so long since the ingestion of the poison and he had vomited repeatedly, there seemed to be no point in washing out the stomach. Oxygen was given through a nitrous oxide bag for five minutes at a time with intervals of 15 minutes instead of constantly through a funnel. Very

[1] W. Watson Cheyne and H. Wilbe: THE LANCET, 1904, i., 1641.
[2] V. Warren Low: Ibid., 1904, i., 1789.
[3] H. A. Lediard and R. E. Sedgwick: Ibid., 1904, ii., 761.
[4] L. R. Braithwaite: Arris and Gale Lecture, 1923, Brit. Jour. Surg., 1924, No. 11, p. 7.

soon there was improvement. The patient became less drowsy and began to resist the application of the face-piece of the gas-bag until consciousness was restored sufficiently for him to be reasoned with, after which he took the oxygen well. After about three-quarters of an hour he had recovered sufficiently to sit up and take some tea, the dilatation of the pupils had become much less and the colour had improved greatly. He was then given mag. sulph. ʒii. with tr. belladonnæ ℥v. and water to ʒii. Oxygen inhalations were continued until noon the following day when they were no longer necessary. The mag. sulph. mixture was repeated twice on successive days.

Progress was uneventful. He felt no ill-effects except headache, which persisted for three days. The blueness gradually cleared off, and was completely gone after three days.

Three weeks later he felt quite well and showed no sign of any ill-effects. He stated that he had less than a teaspoonful of the mixture of aniline and water in his mouth, and thought that he swallowed some of it but was not sure how much. After taking it he noticed a burning sensation in his mouth and immediately began to feel dizzy. The dizziness increased but he was able to go on with his work. Just before he got on the train on his way home, two and a half hours after taking the aniline, he noticed that his legs were becoming weak and that the dizziness was much worse.

Commentary.

Poisoning by aniline may take place in a variety of ways. Glaister[1] quotes cases where poisoning resulted from the application to the ear of cocaine in equal parts of aniline and rectified spirits, where babies were poisoned by napkins which had been marked with marking ink consisting of aniline chloride, where children were poisoned by wearing yellow boots which had been stained with an aniline preparation, and several where poisoning took place through the unbroken skin in workers in industries where aniline was used. It is important to remember that aniline is a constituent in many marking inks.

A point of interest in this case is the demonstration of the importance of using a gas-bag when giving oxygen. This patient had had oxygen given by the funnel method for nine hours without any appreciable effect, and on resorting to the gas-bag an immediate effect was noticed. Skilled attention is not required when oxygen is given from a bag. In this case the boy's mother could use it efficiently after a few minutes' demonstration. The method of giving oxygen through a funnel is both wasteful and ineffective.

I am indebted to Dr. E. J. Burnett for the privilege of seeing this case.

A CASE OF INFLUENZAL ENCEPHALITIS.

BY HERMAN S. N. MENKO, L.R.C.P. & S. EDIN., L.R.F.P. & S. GLASG.,

CLINICAL ASSISTANT, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE obscure symptoms and unusual course in this case present several features of interest.

M. K., a girl aged 4½, showed spots on her body which had been diagnosed as urticaria. Lotions were applied but did not improve the condition. On the seventh day after the appearance of the spots the temperature suddenly rose to 104° F., which remained constant all day. In the evening I was called and found the following: abdomen covered with a rash typical of lichen urticatus; there were also spots on the child's arms and legs; pulse very frequent. Nothing else was found on examination.

The next day the temperature persisted and remained high, without remission. All means and methods of reducing it failed. Quinine had no effect whatsoever, which was rather remarkable, as will subsequently be noted. A consultation was held, but nothing was definitely ascertained beyond the fact that by now the child had severe diarrhœa, with stools which became more and more offensive, and had very much the appearance of those of typhoid. A culture of the stools revealed large growths of *B. coli*, which were also found in large quantities in the urine. The culture did not show any typhoid organism.

There was no doubt at this stage that one had to deal with a definite intestinal toxæmia, and owing to the fact that large numbers of *B. coli* were present, potassium citrate was given in large doses, and colon lavage applied. The child did not improve in the least for three days, in fact, the temperature remained at 104°, and the condition grew rapidly worse, until collapse occurred, and the child to all intents and purposes was in a moribund condition.

After pulse and heart had stopped for about 30 seconds the patient rallied. The same evening another consultation took place, and in view of the fact that alkaline treatment had no effect, hexamine was started, while rectal salines were given frequently, lactic acid and glucose being added to the salines, and whey given by the mouth. No improvement occurred, and after the second day from the beginning of this treatment the child passed into a state of lethargy. Nervous symptoms now made their appearance, some head retraction was noticed, and on the left side Kernig's sign was present. There was also exaggerated extensor plantar reflex; speech had gone, and the patient was unconscious with incontinence of urine and fæces.

The next day, as no improvement was evident, a cerebro-spinal puncture was done, and about 6 c.cm. of clear fluid withdrawn. The fluid was from all points of view normal except that it was under increased pressure. In the night following the puncture the temperature for the first time began to fall. The head retraction disappeared, but some paralysis on the left side persisted. A catheter specimen of the urine showed a very large amount of acetone, the urine being strongly acid. Again alkaline treatment was resorted to, and potassium citrate in large doses given, while rectal salines and saline injections by the buttock, 10 c.cm. at a time, were given.

In the next three or four days the child did not improve and the temperature remained high, although it never reached the same height as before the puncture. Another consultation took place, particular attention being paid to the condition of the central nervous system. Clinically it was decided not to be a case of encephalitis lethargica. Quinine was given again, and the temperature began to fall in contrast with the earlier experience of its use. Gradually everything became normal, speech came back, and the child is making an excellent recovery.

The following difficulties presented themselves in this case: the total absence of any symptoms; the variations in the phenomena observed; the extraordinary reaction of the patient to drugs; the appearance of a rash, which had manifested itself before the onset of fever for ten days. This case, no doubt, was one of severe toxæmia, leading to an influenzal encephalitis. The value of examining the cerebro-spinal fluid shows it not only as a great help for diagnosis, but also, in my opinion, from the therapeutic point of view.

I wish to express my indebtedness to Dr. Theodore Thompson, Dr. Eric Pritchard, Dr. Wilfred Harris, and Dr. Ellison for their valuable help and advice.

[1] Prof. Glaister: Medical Jurisprudence and Toxicology. 1915. Pp. 783.

A PSYCHOPATHIC HOSPITAL AT EDINBURGH.—Following upon the recommendation of the Board of Control for Scotland that it is time to set up "some form of psychopathic hospital" in Edinburgh, the managers of the Royal Hospital at Morningside have taken the matter in hand. They have spent £20,000 in fitting up the Jordanburn Hospital for this purpose and it will be ready to receive in-patients at about the end of the year; an out-patient department has also been designed. There will be room for about 50 patients.

HOSPITALS AND MOTORING ACCIDENTS.—In the first eight months of the present year the Royal Victoria Infirmary, Newcastle-upon-Tyne, dealt with 619 victims of motoring accidents, 295 of whom remained as in-patients, 100 more than in the corresponding period of 1925. The additional burden upon the resources of the hospital is at the rate of £4500 per annum. There are 1700 cases on the waiting-list, which has reached its present dimensions partly as the result of pressure upon beds caused by motoring accidents. Last year Leeds General Infirmary treated 768 such cases, 319 of which stayed for a total of 4740 days, at a cost exceeding £3000. During the last six months the average has worked out at about 1000 cases a year. The daily average of casualty cases of all kinds at Manchester Royal Infirmary is 75.

Reviews and Notices of Books.

RECENT ADVANCES IN MEDICAL AND ALLIED SCIENCES.

Recent Advances in Medicine. Third edition. By G. E. BEAUMONT, M.A., M.D., F.R.C.P., D.P.H., and E. C. DODDS, Ph.D., M.B., B.S., B.Sc. London: J. and A. Churchill. 1926. With 46 illustrations. Pp. 408. 12*s.* 6*d.*

ONLY two years have elapsed since we welcomed the first appearance of this useful book; already a second and third edition have followed in quick succession, and the authors have revised and rewritten several sections. Descriptions of the tests for pus and mucin in urine and of the method of estimation of the calcium-content of the blood have been added. The authors place no reliance on chemical tests for pus and insist on the necessity for microscopic examination of the centrifugalised deposit. The description of colorimetric methods of both blood and urinary analysis has been amplified, and fresh sections have been written on the sedimentation rate of red cells and size variations in anæmia. The account of H. MacLean's method of estimating sugar in blood has been made considerably clearer than it was in the first edition. The sections dealing with sugar metabolism are brought up to date by a new discussion on the action of insulin and of recent work on alimentary glycosuria. The necessity for constant estimations of the blood-sugar in diabetic patients laid a heavy burden on the general practitioner, as well as increasing the discomforts of the patient, and both alike will welcome the suggested method of treatment without blood examinations after the preliminary diagnostic one. The authors regard the method outlined by them as tolerably safe, provided the patient is acquainted with the preliminary symptoms of hypoglycæmia and can resort to sugar if they should appear. Large doses of insulin on an unmodified diet are deprecated, and, in accordance with accepted modern practice, the practitioner is urged to control the sugar output by diet as far as possible and then to prescribe the minimum dose of insulin necessary to keep the blood-sugar within normal limits. The analysis tables showing the caloric and protein, fat and carbohydrate values of different forms of food and the lists of graduated diets are succinct and clear, and the authors have laid the busy practitioner under a still greater debt of gratitude by setting out the graduated diets in the form of daily meals. A new chapter on the treatment and after-care of diabetics has been written for this edition. Chapter VI. contains an enlarged description of the various methods of gastric analysis and a critical estimate of the value of the fractional test-meal. The main utility of the fractional meal is in the investigation of the pyloric function, the examination of cases of achlorhydria, and the diagnosis of carcinoma. The authors point out that the old idea that there is a direct association of hyperchlorhydria with gastric ulceration is not supported by modern investigation. There is an excess of acid and the characteristic "climbing curve" in the fractional meal because there is pylorospasm, and the "climbing curve" is not given when the ulcer is remote from the pylorus. A good deal has been added to the chapter which deals with the liver. The galactose test is described and the account of the phenoltetrachlorphthalein test is enlarged. The van der Bergh test is dealt with fully.

Some beautiful radiograms illustrate the new section on the investigation of the gall-bladder by X rays, and the examination of the lungs after injection with lipiodol. The authors do not enter into the controversy surrounding the Schick test, but describe the reaction with precision. A chapter on the Dick test is included. Cutaneous protein tests, desensitisation, and the peptone treatment of asthma are discussed. The subject of protein shock is not mentioned; some remarks on the pathological basis and therapeutic value of non-specific irritants might well be included in the next edition, for although the bulk of the book is concerned with clinical methods of investigation, useful notes on practically all the latest lines of treatment have been included.

This book has in a short time achieved a signal popularity, which this edition should confirm and extend. Everyone needs to have reliable information on recent advances in medicine, and a combination of physician and biochemist as joint authors is an ideal one. The bibliographies at the end of each chapter are good indications of the latest original work and provide ample opportunity for the reader who wants to follow up any particular problem.

Recent Advances in Biochemistry. By JOHN PRYDE, B.Sc. St. And., M.Sc. Wales, Lecturer in Physiological Chemistry, Welsh National School of Medicine, University of Wales; formerly 1851 Exhibitioner in Chemistry. Same publishers. 1926. Pp. 348. 12*s.* 6*d.*

THE author of this book, as he states in the preface, has experienced great difficulty in selecting topics suitable for his purpose from the many branches of biochemistry. He has necessarily omitted many interesting and instructive aspects of the question, since under the heading biochemistry are now included chemical pathology and the chemistry of naturally occurring substances and their industrial aspect. Mr. Pryde has selected for notice the more purely chemical and physico-chemical aspects of substances of physiological importance, though in a book of this size he has obviously been unable to cover the whole field.

The book opens with an excellent chapter on protein catabolism; his description gives a clear idea of the deaminisation and oxidation of urea, which will be new to many, though the captious might complain that this work can hardly be termed "recent"; the references at the end of the chapter show that much of the work described dates from 1912, 1910, and even 1902. The second chapter is concerned with recent theories as regards the physical chemistry of the proteins, and supplies a readable account of the views of the late Prof. Loeb. The subject is a difficult one to explain in a few words, and Mr. Pryde deserves tribute for elucidating it. Chapter III. on the nucleo-proteins well summarises the more recent work of Walter Jones, Levene, and other workers. The references to this section are good, though for the benefit of the general reader some of the work on the synthesis of purines in the laboratory, notably Emil Fischer's researches, might have been included. The chapter on carbohydrates is perhaps the most valuable one in the whole book. The structure and biological utilisation of the different carbohydrates and their metabolism are admirably dealt with, and the accounts of some of the recent laboratory work on the constitution of these substances leave nothing to be desired. Succeeding chapters are devoted to the fats, phosphorus compounds, and sulphur. Into a brief space Mr. Pryde has compressed a detailed account of the occurrence of the various vitamins and of their importance, and an excellent series of references is included. The three final chapters on hæmoglobin, the chemical basis of specific immunological reactions, and chemotherapy are interesting as summaries of recent work, but give the impression that Mr. Pryde takes a more perfunctory interest in these studies and that the preparation of these chapters was less a labour of love than a duty.

As a whole this book will be found of the utmost value, not only to students who wish to have clear and accurate summaries of work which at the moment can only be found in special journals, but also to laboratory workers who may not have the time to study original papers in any other line of work than that on which they are engaged.

Recent Advances in Physiology. Second edition. By C. LOVATT EVANS, D.Sc. Lond., M.R.C.S., L.R.C.P., F.R.S., Jodrell Professor of Physiology, University College, London. Same publishers. 1926. Pp. 370. 12*s.* 6*d.*

THE changes of note in this excellent summary of the latest additions to physiological knowledge are few in number but of great significance. Thanks to the brilliant investigations of Dr. C. R. Harington at University College Hospital Medical School, the structure of thyroxin has been definitely determined, and the final compound all but completely synthesised. Of great practical importance is the same worker's new method for extracting the hormone from the crude thyroid tissue, a method which gives a yield of about 0·03 per cent. of the fresh gland. It will be remembered that Kendall was able to obtain a yield of only 0·001 per cent. by his method. The thirty-fold increase obtained by Dr. Harington will inevitably bring down the cost of extracting thyroxin, a cost which before was prohibitively large, to a level which will enable the drug to be produced on a commercial basis. Medical men should shortly be in a position to administer definite and known amounts of the active principle of the thyroid gland and no longer to be dependent on preparations, the dose of which, in the absence of an accurate method of assay, must be difficult to gauge.

A second important addition to this volume is the account of the mechanism of the action of insulin, which has now been brought to a satisfactory and comprehensible standpoint by the recent work carried out at the National Institute for Medical Research. By making use of the spinal eviscerated animal with constant infusion of glucose it has been shown that the administration of insulin causes an increase in the glycogen reserves and in the oxygen consumption of the preparation. Further, an accurate balance-sheet has been constructed between the amount of sugar disappearing from the blood on the one hand, and that partly deposited as glycogen and partly oxidised to CO_2 and H_2O on the other. The disappearance of glycogen from the muscles, which had been so repeatedly observed after large doses of insulin, has been shown to be due to the convulsions associated with the fall in blood-sugar. These convulsions, of course, do not occur in the spinal preparation. Further, insulin inhibits the transformation of protein and fat to carbohydrate, a transformation which we know to be abnormally great in cases of diabetes mellitus. An excess of insulin therefore causes the metabolism of the animal to swing entirely to the carbohydrate side, so that in the absence of a sufficiency of glycogen both the respiratory exchange and body temperature gradually fall.

We commend this fascinating volume whole heartedly to those students of biology and medicine who wish to obtain a scientific insight into some of the more important problems with which physiologists are grappling at the present time.

CHRONIC INTESTINAL STASIS.

A Radiological Study. Second edition. By ALFRED C. JORDAN, C.B.E., M.D. Camb., M.R.C.P. Lond., Corresponding Foreign Member, Belgian Royal Academy of Medicine. London: Humphrey Milford, Oxford University Press. 1926. Pp. 230. 21*s.*

THE first edition of this volume appeared in 1923, and the new edition contains no changes of outstanding importance. This book is of particular interest because many of the author's conclusions are not shared by the majority of his colleagues. The impartial reader is left with the impression that the whole argument of the book is designed to prove that intestinal stasis is a factor of far greater universal incidence and importance than most authorities believe, and, as was said in the review of the first edition, the author is safest when examining the intestinal viscera almost wholly from the point of view of the skilled radiologist. The pictures, many of which compare unfavourably with present-day standards, do not reinforce the argument; they are too often unconvincing. The chapter on the author's own apparatus should either have been left out or brought up to date, especially in regard to the interpretation of the "stasis" shown. For example, ileal stasis is present in practically every healthy patient who has any degree of constipation, and readily disappears when the bowels are cleared so that the food can pass on; therefore, since the author's rule is to allow no aperient to be taken for two days prior to the X ray examination, not much can be deduced from the examples of ileal stasis depicted. Dr. Jordan's book can be recommended as an able exposition of those extreme theories of the dangers of intestinal stasis which are held by a section of the medical public.

A MANUAL OF CLINICAL PROCEDURE.

By ROBERT A. KILDUFFE, A.B., A.M., M.D., Director of the Laboratories, the Atlantic City Hospital. London: Henry Kimpton. 1926. Pp. 287. 12*s.* 6*d.*

THE author states in his preface that he has set out to write a manual of laboratory practice suitable for the general practitioner, and he has succeeded admirably. He has kept a steady and unwavering eye upon his chosen audience—the family doctor who wants to push the diagnosis of his cases beyond the limits that can be achieved by the use of his five senses, even when one of them is aided by the stethoscope. The selection of matter is excellent and the procedures described could readily be performed with the minimum of equipment. The more elaborate methods of diagnosis, such as those involving fixation of complement and so forth, are omitted, though the indications for their performance and the interpretation of their results are fully discussed. An admirable little book.

THE PATHOGENESIS OF CHRONIC GASTRIC ULCER.

Die Pathogenese des Chronischen Magendarmgeschwürs. By Dr. J. R. F. RASSERS, Gastroenterologist at the Reichs-Universität, Leiden. Leiden: S. C. Van Doesburgh. 1926. Pp. 69.

THIS is an interesting monograph in which the author seeks to prove, by the experimental method, that gastric ulcers arise from a failure of the protective mechanism against self-digestion, due to lack of sodium ions in the gastric mucosa. He obtained ulcers in the stomach and duodenum by pouring acid pepsin solution daily into the stomachs of dogs, living on a diet deficient in sodium chloride. The book is well worth reading, though the relation of the findings to human gastric ulcer are not always brought out convincingly.

TUMOURS OF THE COLON AND RECTUM.

By JEROME M. LYNCH, M.D., Surgical Director, St. Bartholomew's Hospital, N.Y.; and JOSEPH FELSON, M.D., Attending Pathologist, St. Bartholomew's Hospital, N.Y. New York: Paul B. Hoeber. 1925. Pp. 259. $12.00.

THOUGH this is a very well-printed monograph, it is difficult to read. It consists of a compilation of the literature, a number of cases being interspersed, and lacks the personal note so valuable in contributions of this kind. The chapter on operative treatment is sketchy, but the authors claim "beautiful results in carcinomata of the rectum" by an interesting method, in which the growth is removed by the abdominal route, leaving a colostomy and the anal canal, continuity of the alimentary channel being restored 6–12 months later. On p. 168 there are important misprints on line 4, where "above" appears for "below," and line 11, where "prone" appears for "supine." The book is not likely to make a strong appeal to English readers.

STUDENTS' GUIDE—SESSION 1926–27.

DENTAL SURGERY.

(*Continued from p. 712.*)

TEACHING INSTITUTIONS IN DENTISTRY.

OF teaching institutions those connected with the several universities have now been described in some detail, but in addition to these there are a number of institutions which offer facilities to dental students and which are here set out under their localities.

LONDON.

Royal Dental Hospital of London, School of Dental Surgery, Leicester-square.—A school of the University of London. Women are now admitted as students and are eligible for all hospital appointments and school prizes. The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 5 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the training in dental mechanics recognised by the curriculum. The instructors at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for four months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £25. One Entrance Scholarship in Dental Mechanics and Metallurgy, value £25, open to pupils of the Hospital only. One Entrance Scholarship of £25 in Dental Mechanics, open to pupils of private practitioners. The Saunders Scholarship of £20 and Saunders Prize of £5 awarded to second year students. The Storer Bennett Research Scholarship for Scientific Research in any branch of Dental Surgery, value £50, is awarded triennially. The Alfred Woodhouse Scholarship of £35 and the Robert Woodhouse Prize of £10 for Practical Dental Surgery. The "Lonnon" Bursary of £25 for second year students. The "J. A. Smith" Scholarship of £50 for students in their first year's hospital practice. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses at the end of the summer and winter sessions. Fee for two years' hospital practice required by the curriculum, including lectures, £70 in one payment, or £73 10*s.* in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £52 10*s.* Both hospitals can be attended simultaneously. For the lectures in Chemistry and Physics for the Preliminary Science or Pre-Medical Examination £13 13*s.* The fee for the instruction in Dental Mechanics and the two years' hospital practice required by the curriculum is £200 if paid in one instalment, or 200 guineas if paid in three equal instalments. The fee for tuition in Dental Mechanics is £70 per annum; for one year's hospital practice £28.

University College Hospital Dental School, corner of Great Portland and Devonshire-streets, W.—This Hospital and School has recently been thoroughly reorganised, and is now fully equipped with all the most modern appliances. Students are entered as students of University College Hospital, and, as such, attend the classes of Anatomy and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the National Dental Hospital, the first Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. A calendar containing full information as to lectures, fees, prizes, &c., may be had on application to the Sub-Dean for Dental Students, who attends at University College Hospital Medical School, University street, W.C. 1, on Tuesday and Friday mornings at 10.30 o'clock.

Guy's Hospital.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. The Extraction Rooms: There is ample accommodation for both general and local anæsthetic extractions, together with waiting- and retiring-rooms. Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the staff demonstrators, the dental house surgeons, and the dressers. The Conservation Room is open from 9 A.M. till 5 P.M. It has a floor space of over 7000 square feet, and affords accommodation for about 100 dental chairs, with the necessary equipment of the most modern type for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. There is a separate room for dentine patients affording accommodation for 15 chairs. The Members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Prosthetic Laboratory. The Probationers' Laboratory is supervised by three of the staff demonstrators, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of clinical study. Students in Dental Prosthetics are received, and a graded, systematic, and full course of instruction, extending over two years, is carried out under the supervision of the Director of the Prosthetic Laboratory, assisted by two demonstrators and five mechanics. Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the B.D.S. Lond. or L.D.S. Eng.—viz., the complete course in dental prosthetics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. Two Entrance Scholarships are awarded in July of each year, a War Memorial Scholarship in Arts of the annual value of £40 for four years; and a Junior Science Scholarship of the value of £40 per annum for not more than four years. Prizes of the aggregate value of £40 are awarded for general proficiency and for skill in Operative Dentistry. The Newland-Pedley Gold Medal for Operative Dentistry is also awarded annually. Dental students enjoy the privileges of students in the Medical School. Application for studentship should be made to the Dean of the Medical School.

Appointments: All appointments are made according to the merits of the candidates, as determined by a committee of the Dental Staff. Eighteen house surgeons, 15 assistant house surgeons, and four student demonstrators of Dental Histology are appointed annually. The following appointments are held by students: Full surgeon's dresser, assistant surgeon's dresser, dresser in the children's department, casualty dresser, clerk to the anæsthetist, dresser in the gas extraction and local anæsthetic extraction rooms, and probationary dresser.

King's College Hospital.—The Dental School is part of the Medical School of King's College Hospital, and was opened in November, 1923. The Dental Out-patient Department of the Hospital is used for the performance of dental extractions. A large

Conservation Room with provision for 40 dental chairs has been equipped. Smaller rooms are used for clinical teaching and administrative requirements, and a specially equipped laboratory for training in the art of dental mechanics. An X ray apparatus has been installed for special use in dental skiagraphy. A museum containing a large number of specimens illustrating oral, buccal, dental, and other diseases is available for teaching purposes. The library, lecture theatre, lecture rooms, common rooms, and the refreshment room are all available for the use of students. Courses of study, including practical work, are provided for the degree of Bachelor of Dental Surgery of the University of London, and for the Diploma in Dental Surgery of the Royal College of Surgeons of England. Special arrangements are made for those students who wish to take a medical degree or qualification in addition to a degree or diploma in Dental Surgery. Full particulars of the Dental School may be obtained on application to the Dean, Dr. H. Willoughby Lyle, or to the Secretary, Mr. S. C. Ranner, M.A., King's College Hospital, Denmark Hill, London, S.E. 5.

London Hospital.—This school is a part of the London Hospital and Medical College, and is fully equipped on the most modern lines and with the latest appliances. It provides a complete curriculum in all subjects for the B.D.S. Degree and for the L.D.S. Diploma, and is admirably adapted for the purpose of teaching. The Conservation Room is well lighted and ventilated and fitted with pump chairs of the latest pattern; the fountain spittoons at many of the chairs have been specially designed. Each spittoon has attached to it a saliva ejector, hot and cold water, compressed air, gas and electric current, also a swing bracket to carry the students' cabinet. Electric sterilisers are supplied in each department and motor engines where required. The School possesses in addition to the Theatres, Laboratories and Museums in the College, a special Museum of Dental Anatomy and Surgery, Operative Dentistry, Prosthetic and Extraction Rooms, and Laboratories for Practical Metallurgy and Prosthesis. A systematic course of instruction is arranged for pupils. The up-to-date Laboratory contains every modern apparatus and is in charge of a skilled curator and his assistants. Connected with the Medical College and Dental School are a Library, Athenæum, Clubs' Union, Dining Hall with moderate tariff, Students' Hostel, and an Athletic Ground. For full particulars as to Scholarships and Prizes, fees and course of study advised, apply to the Dean, Prof. William Wright, who will be glad to make arrangements for anyone wishing to see the Dental School and Medical College.

London (Royal Free Hospital) School of Medicine for Women.—Full courses are arranged for women students, in conjunction with the Royal Dental Hospital, Leicester-square, for the study of dentistry, and in preparation for the B.D.S. Degree of the University of London and the Licence in Dental Surgery of the Royal College of Surgeons of England, at the London (Royal Free Hospital) School of Medicine for Women.

PROVINCIAL.

Birmingham Dental Hospital, Great Charles-street.—Dean: Cyril Howkins, C.B.E., D.S.O., M.R.C.S., L.D.S. The Dental Hospital was founded in 1858, and was recognised by the Royal College of Surgeons in 1880 for the teaching of Dental Students. Having an annual attendance of about 21,000 patients, it affords every advantage for students about to enter the profession to acquire a thorough practical knowledge, as required by the Medical Council. The present very fine building, which compares favourably with any similar institution, was opened on July 6th, 1905. It has accommodation for 100 students. The equipment is in accordance with the most modern requirements for the efficient teaching and practice of Dental Surgery, including Radiology and Ultra-Violet Ray Therapy and a new department for Practical Pathology and Bacteriology. The operations performed annually average 35,000, including gold and other fillings, crowns, bridges, porcelain inlays, and injections for block and infiltration anæsthesia. The orthodontic department is one of the foremost in the country. The Prosthetic and Mechanical Department is large and well lighted and under a highly skilled instructor who is always present. By arrangements with the Birmingham University and with the General and Queen's Hospitals the entire course of Lectures, Hospital Practice, &c., may be completed for an inclusive fee of £144 4*s.* 6*d.*, or including Mechanical Pupilage, £255 15*s.* 9d., inclusive of Examination fees for L.D.S. Birm. The instruments and materials necessary for Hospital Practice cost about £45. The Composition Fee for the courses required for the L.D.S. of the University, or any of the Corporations alone, is £75, payable in two annual instalments at the commencement of the first and second years; that for the courses required for the L.D.S. and the Degree in Dentistry of the University is £93 15*s.*; that for the L.D.S. in combination with the M.R.C.S. and L.R.C.P. is £115; and that for the M.B., Ch.B., and B.D.S. is £120. All of these composition fees are payable in two annual instalments at the commencement of the first and second years. Each of these fees covers the cost of the courses given at the University for the qualifications indicated, but does not include fees for Hospital teaching, nor Pre-Dental year Chemistry and Physics. For two years' dental hospital practice the fee is £26 5*s.*, payable in two instalments of £13 2*s.* 6*d.* each at the commencement of the first and second (hospital) years respectively. For two years' mechanical pupilage, £111 11*s.* 3*d.*, which may be paid in two annual instalments of £65 12*s.* 6*d.* and £45 18*s.* 9*d.* respectively; mechanical pupils may join for a probationary period of one month, fee £6 11*s.* 3*d.*, which is deducted upon payment of the full amount. For general surgical hospital practice, lectures, and demonstrations: Surgery, two winters, £13 2*s.* 6*d.* A Dental Scholarship is offered annually of the value of £37 10*s.* It is awarded to the student who, entering for the Dental Degree of the University, shall pass the best examination in the subjects studied during his apprenticeship. Application for admission must be sent to the Dean of the Medical Faculty, Birmingham University, or the Dean of the Dental Hospital, Birmingham.

Leeds University School of Dentistry.—The School of Dentistry is adequately equipped to provide for the complete training of the dental student. The School forms a part of the Leeds School of Medicine, whilst the instruction in clinical and mechanical dentistry is carried out in the Dental Hospital at the General Infirmary. The courses of study are mainly designed to meet the requirements of the B.Ch.D. and L.D.S. Leeds, but every opportunity is afforded to students preparing for the degrees or diplomas of other licensing bodies. Full-time demonstrators give the instruction in clinical dental surgery, prosthetic dentistry, and mechanics, which is carried out under the supervision and direction of members of the Honorary Staff, two of whom are in attendance each day. Special facilities are provided for instruction in Orthodontia, Dental Radiography, Local and General Anæsthetics. Prizes are offered for competition to pupils and students in their respective years of study. Communications should be addressed to the Warden, School of Dentistry, Leeds, from whom a prospectus may be obtained.

Dental Hospital of Manchester.—This hospital is in association for teaching purposes with the University of Manchester and the Royal Infirmary, and is in the centre of a very large population. Courses of study are provided to meet the requirements of the various examining bodies, including those of the University of Manchester for the qualifications L.D.S. and B.D.S., and the L.D.S. of the Royal College of

Surgeons of England. Clinical instruction is given in Dental Prosthetics, Operative Dentistry, Diagnosis and Extraction, Orthodontics, Dental Surgery, Radiography, and Anæsthetics by specially appointed Clinical Teachers.

For the whole course of hospital instruction for the L.D.S. (including two years' mechanical training) the fee is £131 5*s*., paid in instalments. For the two years' Operative Course only, £26 5*s*., paid in two instalments. For the whole course of hospital instruction for the B.D.S. degree (including mechanical training), £168, paid in instalments. In accordance with the new regulations, L.D.S. students who have taken two years' training in practical Dental Mechanics with a registered practitioner are required to take a further year in the Hospital mechanical laboratory, the fee for this being £63. All the courses of instruction are open to women students. Copies of the Prospectus will be forwarded on application to Mr. J. Hilditch Mathews, Dean.

Newcastle-upon-Tyne Dental Hospital and School.—This hospital is centrally situated (within five minutes of the various colleges, infirmary, and railway station); the rooms are well lighted and thoroughly equipped for carrying on the work. Dental surgeons and an anæsthetist attend each morning. A tutorial dental surgeon and a prosthetic tutor is also in attendance. The Composition Fee for the special Dental Lectures and Dental Hospital Practice is £60 4*s*. if paid in one sum, or £62 6*s*. if paid in two instalments of £31 3*s*. The Composition Fee for the Lectures at the Colleges of Medicine and Science is £67 10*s*.; in addition to this there is a library and an athletic club fee. The fee for General Hospital Practice at the Royal Victoria Infirmary, Newcastle-upon-Tyne, is £23 2*s*. Medals and Certificates of Merit are granted to students showing certain standards of proficiency in the various classes at the Dental School. The prospectus of the Dental Hospital and School, containing full information, may be obtained from Mr. James Coltman, 13, Ellison-place, Newcastle-upon-Tyne, Dean.

Devon and Exeter Dental Hospital, 24, Southernhay West, Exeter.—Established 1880.—The hospital is open on Mondays, Tuesdays, Wednesdays, Thursdays, Fridays, and Saturdays, and patients are admitted between the hours of 9.30 and 11 A.M. Students attend the practice of the hospital under the control of the medical officers. Honorary treasurer, Mr. J. M. Ackland; secretary, Mr. Albert G. Littlejohn.

SCOTLAND.

The Incorporated Edinburgh Dental Hospital and School.—The Edinburgh Dental Hospital and School is located in spacious and well-equipped buildings at 30, 31, and 32, Chambers-street, and offers special advantages to dental students. A large and important extension of the existing buildings is now in process of construction. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The general hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. The cost of the hospital outfit of instruments is included in the Dental Hospital fee of £42. The minimum cost of classes and Diploma for the whole course of dental instruction amounts to £123. Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow is recommended. The minimum cost of Professional Education, the Triple Qualification, and the Licence in Dental Surgery amounts to £202 8*s*. 6*d*. The Higher Dental Diploma (H.D.D.) of the Royal College of Surgeons affords an opportunity of obtaining a higher qualification subsequent to registration. The Prospectus, with full information, may be obtained by application to the Dean or the Assistant Secretary.

Incorporated Glasgow Dental Hospital, 158, Renfrew-street and 15, Dalhousie-street, Glasgow.—The School is open to Men and Women Students, and Lectures are given on Dental Surgery, Operative Dental Surgery, Orthodontia, Dental Anatomy and Physiology, Dental Histology, Dental Mechanics, Crown and Bridge work, Dental Metallurgy, Dental Bacteriology, Radiology, Anæsthetics, and Dental Materia Medica. Lectures on general subjects required for Dentistry may be taken at the University or at one of the extra-mural schools where special provision is made for Dental Students. Composition fee for two years' Hospital Practice and Lectures special to Dentistry, £60 on entry, or in two instalments of £35 and £30. A new mechanical laboratory with bench accommodation for 60 pupils and fully equipped with the most modern appliances for teaching practical dental mechanics has recently been added. Fee for two years' tuition, £63, or in two instalments. Full information may be had on application to the Dean.

Glasgow Royal Infirmary (Dental Department).—Mr. W. R. Taylor attends at the Royal Infirmary at 9 A.M. on Wednesdays and other days as arranged. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital.

IRELAND.

Incorporated Dental Hospital of Ireland, Lincoln-place, Dublin.—All Dental Students who have passed their First Dental Examination in the Royal College of Surgeons in Ireland (or an equivalent examination or examinations) are admissible to the Clinical Instruction of the Hospital. In addition to Clinical Instruction and Special Demonstrations, courses of lectures are given at the hospital on Dental Surgery and Pathology, Mechanical Dentistry, the Administration of Anæsthetics, Orthodontia, Dental Anatomy, and Dental Materia Medica, and instruction in Anæsthetics. Fees: Hospital Practice (each year), £18 18*s*.; Lectures, £5 5*s*. The course in practical Dental Mechanics can be taken in the Hospital Laboratory. Further particulars can be obtained from the Dean.

CIGARETTE CARDS FOR HOSPITALS.—Mr. George Giddings, of Coldharbour-lane, Camberwell, who has been paralysed since childhood, has collected cigarette cards to the number, he estimates, of millions. He began doing so as a hobby, but eventually let it be known that he was prepared to amass and sell cards to complete collections, the proceeds to go the Red Cross during the war. Since 1919 he has continued the work on behalf of King's College Hospital, where he supports a cot. Altogether he has contributed nearly £1000 to the Red Cross and the hospital. None of the cards are bought; they are all sent to Mr. Giddings by people who have heard of what he is doing, and he receives them in such large numbers that he is always able to complete imperfect collections.

THE LANCET.

LONDON: SATURDAY, OCTOBER 9, 1926.

THE MEDICAL LIFE.

MANY aspects of the medical life were presented by professional leaders last week to the students assembled at the various teaching schools for the opening of the winter session, and those which we publish to-day in abridgment may all be said to deliver the common message that the medical life is a full and fine one, calling for the exercise of high practical as well as scientific qualities, and affording opportunities for the exercise of these qualities in many varied forms. For the students at King's College Hospital this last point was made the subject of the introductory address, in which Sir HUMPHRY ROLLESTON reviewed the various careers of practitioners, contrasting their financial rewards with those which were obtained, for example, by barristers, and indicating once again the obvious fact that the general practitioner is, and must be, the backbone of the profession. Wisely he commenced his address with a warning against too early specialisation as he set before his audience a picture of the diverse careers that entry of the medical ranks offers, while he outlined the direction in which development and evolution were occurring.

A survey of the medical profession at once reveals the varied opportunities that the medical life holds out to men of different bents of mind. The general practitioner, the consulting physician, the operating surgeon, the holder of purely scientific appointments, the officer in Government and municipal employ, the medical manager of institutions, the medical officer in the Services, lead careers which differ entirely, though the reason for their working lives—the prevention and remedy of disease—is common to all. For some life will be essentially adventurous; for others it will be spent in two or three wards, an operating theatre, and a consulting-room. Some will be the trusted friends of the great; socially, many exclusive doors will be open to them and intercourse with intellectual leaders of all sorts will be their right: others will serve under authorities and municipalities composed of men whose education and position may not be equal to their own, even while the wide extension of public culture is allowed for; and some will live in daily and intimate intercourse with the poor. The man who loves the study of his fellows has social and psychological problems unrolled before him from hour to hour—he sees naked souls as well as naked bodies, and has to take the treatment of both into his consideration. No special application of psychological knowledge can alter the position that the sound doctor must be to a great extent, and always, a sound psychologist; and every general practitioner knows this so well that he seldom alludes to its obviousness. He whose sympathies are rather with the theory than with the practice of his art can exert his energies in the class-room or laboratory without coming into collision with the public. The sportsman can indulge his proclivities in moderation whilst discharging his professional duties with zeal, though small will be his chances of success if the zeal is manifested too much over the sport and the moderation is applied to his appetite for his duties. All sorts of persons in all sorts of methods and under all sorts of skies can carry on the profession of medicine, so that there need not be many to whom the medical life is irksome, though there must be few for whom it is not arduous. There will be an unfortunate minority, who, being by Nature designed for work of one kind, have by stress of circumstances been forced into a different groove. Probably they did not discover their own tastes until it was too late to work in the necessary direction, and this error is a very difficult one to rectify, whatever calling a man may adopt. But, speaking generally, the profession of medicine has this first advantage for its British disciples—an advantage which members of other nations do not enjoy—it offers a career that can be varied to suit all inclinations. Further, a high percentage of the followers of medicine attain to a fair degree of success, and the total failures are comparatively infrequent. These things must always be remembered, for while certain circumstances may be held to detract from the medical life—the tyranny of many of its conditions, for example, and the strain of many of its conjunctures—they establish it as a good life, offering chances to a man with brains and energies, a large choice in the sphere of labour, and to a fitting extent an opening for individuality, even while obeying the restrictions entailed by the world.

That the medical life, despite its common objective remaining ever the same, will be changing perpetually as knowledge of medicine progresses, was the message of Sir ARCHIBALD GARROD to the students at Westminster Hospital. He pointed out that with the development of clinical medicine, which has been so striking a feature throughout the last 50 years, there has come for the doctor of to-day numerous alternatives in professional life which did not exist for his immediate forerunners. The student of 50 years ago had to regard his studies as leading up to one of three or four methods of making a livelihood. Pathology was synonymous with morbid anatomy, and of those scientific developments in medicine, which are the pride of our time, the foundations were only being laid, largely by medical men in the intervals of practice. There were no bacteriologists and the whole of the biochemist's story remained to be told. But the vitality of medicine is here illustrated excellently by the fact that, as the separate branches of the medical life have become more differentiated, intensive study along the various lines continues to reveal gaps in our knowledge previously undetected, affording boundless opportunities for research. Here the words of Sir WALTER FLETCHER at the opening of the session of the London School of Medicine for Women are exactly apposite. "It is not very bold," he said, "to think that the physician is likely to find his powers and scope changing rapidly in many ways as we lay hold of the elements of a scientific knowledge of nutrition and begin to use its enormous latent powers." Everyone who tries to keep abreast with the literature of our calling will have noted the increasing authority with which it is possible to speak on the manifold problems of nutrition, and will also have noted the many places where theories require confirmation and statements ask for support, both of which will have to come from the men and women who are doing the clinical work. "The practical doctor has greater opportunities to carry on investigations bearing directly on the treatment of disease than the laboratory worker," said Prof. THOMAS YEATES to the Middlesex Hospital students, and this an inspiring thought for all, gains force from the high position of clinical teaching in this country,

Dr. GRAHAM LITTLE, in his address to the students at St. George's Hospital, the provocative nature of which he has since admitted to have been intentional, mentioned the insistence which has been laid always in British schools upon the importance of clinical training. Our men are thus fitted, while discharging the duties of practice, to collect and collate those clinical facts upon which science depends in its march, and at any occasion where medical training is the subject of oratory or debate, it is well that this gratifying fact should be insisted upon. The high clinical level of the general body is the guarantee that our medicine is sound and moving forward.

WELFARE OF THE BLIND.

THE sixth report of the Advisory Committee on the Welfare of the Blind to the Ministry of Health [1] records the advances of the last two years. As many as 90 per cent. of the blind population over 50 years of age are now receiving the old-age pension, the remaining 10 per cent. being presumably in the possession of other means. The expenditure of local authorities in connexion with the Blind Persons Act has risen from £14,671 in 1921–22 to £127,593 in 1925–26, and it is satisfactory to know that in spite of this the income of voluntary agencies from subscriptions and donations has risen to over £400,000 in 1923–24. These sums are supplemented by grants from the Ministry of Health to an amount which now exceeds £100,000, the greater part of which money consists in grants made for employment purposes to workshops and home workers, but a substantial part of which goes to the provision of "home teaching" to blind persons classed as "unemployable."

The total number of the blind population of England and Wales in 1925 was said to be 42,140, but we think that in one respect the statistics are incomplete. The table showing the distribution of blindness according to age-periods shows 0·6 per cent. under 5 years old, whereas in the table showing the ages at which blindness was acquired it appears that about one-fifth became blind within the first year of life (a fact due partly to congenital blindness and partly to ophthalmia neonatorum). Is it that a considerable proportion of children under school age escape registration? On the other hand, the dividing line between "blind" and "not blind" is not easy to draw, and a recent circular of the Ministry of Health draws attention to the varying standards which have been adopted. The definition "too blind to perform work for which eyesight is essential," which is found in the Ministry's regulations is obviously quite vague for the purposes of statistics. Out of a total of 39,163 blind persons over the age of 16, only 8840 were actually employed, but it is satisfactory to find that the number under training increased between 1923 and 1925 from 1246 to 1621. Of the 26,826 blind classed as "unemployable" a few have private means, and some are married women occupied with domestic duties, but the great bulk, the report states, are definitely incapable of performing any work of an economic worth. For their benefit each local authority in consultation with voluntary agencies, and with the sanction of the Ministry of Health, has drawn up schemes of assistance, both social and financial, the income being generally made up to 25*s*. a week or higher. In the case of the employed blind the earnings are generally supplemented on a sliding scale, and with a view to the promotion of a greater degree of uniformity a definite scale of augmentation is recommended by the Ministry as a general national minimum.

The report contains some reference to partially blind children for whom the total accommodation at present available in myope schools and myope classes is sadly deficient. We would call special attention to the warning "that any restriction at the present time in the development of sight conservation classes would be a very regrettable, and in the long run, an uneconomical measure." The hope is expressed "that it will be possible for the Board to proceed with their full programme for the development of extended facilities for the education of this class." More consideration is needed to help parents in a choice of career for their children with weak sight, whether due to myopia or to some other cause, and the case of that considerable class of adults who become weak-sighted in later life without being so blind as to qualify for State assistance might well be commended to voluntary effort.

IRRADIATION AND CELL-DIVISION.

THE therapeutic value of X rays and radium is based on the fact that certain tissues, of which cancerous tissue is one, are more sensitive than others to the destructive action of these radiations. Of normal tissues the lymphoid tissue and the testis are particularly sensitive to irradiation, and this selective action goes even so far as to distinguish between different cells of the testis; the cells of Sertoli are much more resistant to radiation than the cells engaged in spermatogenesis, and the interstitial cells may even hypertrophy when the seminiferous tubules atrophy after irradiation. Since all the tissues which are specially sensitive to irradiation are growing tissues in which active cell-division is going on, it has been assumed in explanation of the selective action of irradiation that cells in the process of mitosis are particularly sensitive. This view is expressed in what is called the law of Bergonié and Tribondeau, which may be formulated as follows: "Immature cells and cells in an active state of division are more sensitive to irradiation than are cells which have already acquired their fixed adult morphological or physiological character."

Several recent publications throw doubt on the correctness of this explanation. STRANGEWAYS and his collaborators [1] have studied the effect of exposure to X rays on cells cultivated in vitro, using choroid cells of the embryo chick as the test object. They found a distinct diminution in the number of cells in mitosis if the irradiated cultures were examined after having been incubated for 80 minutes after exposure. This effect was obtained even with very small doses of X rays, so that the authors are inclined to look upon it as a particularly delicate test of biological response to irradiation. No stimulating effect was obtained even with the smallest doses. With increasing dosage the effect became more and more marked, so that with the largest dose given there was a complete cessation of mitosis. By direct observation under the microscope on the warm stage the surprising result was obtained that the cells which were already in some stage of mitosis—even the earliest prophase—before irradiation began, passed through the remaining phases of cell-division and gave rise to two daughter cells. The inhibition of cell-division is therefore not due to injury or disintegration of cells

[1] T. S. P. Strangeways and H. E. M. Oakeley: Proc. Roy. Soc. B., 1923, xcv., 373. Strangeways and F. L. Hopwood: Ibid., 1926, c., 283.

actually passing through the process of mitosis. It must therefore be due to an inhibitory effect on the resting (i.e., non-dividing) cells whereby these are prevented from entering into the process of mitosis. From this inhibition the cells can recover if only small doses of X rays have been applied. The cells begin to divide again normally after five hours and the irradiated in vitro culture can be successfully subcultured an indefinite number of times. With larger doses, however, the mitoses which appear are abnormal and the cells disintegrate. STRANGEWAYS and HOPWOOD state categorically that "cells undergoing mitosis are unaffected by X radiation," apparently basing their statement on the observation that exposure of dividing cells to doses so large as to produce permanent damage if applied to non-dividing cells does not prevent dividing cells from completing mitosis and giving rise to two daughter cells. But the possibility remains that the subsequent history of the daughter cells may afford evidence of some permanent injury, and the paper does not contain any observations which would exclude this. It would certainly be remarkable if the process of mitosis should render an otherwise sensitive cell completely resistant to irradiation.

Strikingly similar results have been obtained by J. C. MOTTRAM, G. M. SCOTT, and S. RUSS[2] from a study of the effect of beta rays from radium upon the cells of a transplantable rat sarcoma. After radium had been applied over the tumour a piece of it was removed and the number of mitoses in a radiated and a non-radiated tumour compared by means of stained sections. An hour after exposure an almost complete absence of mitosis was noted in the irradiated tumour, although at the time of exposure numerous cells could be seen in mitosis. After a period varying with the size of the dose there was a return of cells showing mitosis, even when doses had been given so large that, applied to the tumour in vitro, the cells on transplantation would have been unable to produce a new tumour. They explain these curiously paradoxical phenomena in the light of STRANGEWAY'S work as being due to an inhibition of the cells from entering into the phase of mitosis, the process of mitosis itself being unaffected by irradiation. These observations raise a number of interesting problems. It is obvious that we must discard the old explanation which attributes the special sensitiveness to irradiation of growing tissues to the presence of cells in the phase of mitosis. Although cytologically the resting cells of a growing tissue are not different from the cells of a non-growing tissue, these observations show that they differ biologically in their sensitiveness to irradiation. Such sensitiveness must be due to some property which the cells of all growing tissues have in common and which is presumably connected with the process of growth. Since this applies to normal growing cells as well as to cancer cells, it would appear that the mechanism of growth is essentially the same in both.

ST. LUKE'S DAY.—There will be a special service at St. Martin's Church, Trafalgar-square, W.C., on the evening of Monday, Oct. 18th. To this service, which commences at 7.45 P.M., all members of the medical and nursing professions will be welcome. The service will take the form of thanksgiving for health and a prayer for the sick and suffering, and the preacher will be Dr. Arthur Lankester. Dr. Lankester went out to India in 1891 and was stationed at the Church Missionary Society's Hospital at Amritsar. Subsequently he took charge of the hospital at Peshawar, N.W. Frontier. He has been decorated for public services in India and his research work in connexion with tuberculosis.

Annotations.

"Ne quid nimis."

COAL AND HOSPITALS.

THE long continuance of the coal strike and the rapid approach of the time when the sun can no longer be depended upon to warm wards and offices is causing serious anxiety to the authorities of most of the hospitals in the country. For two or three days in the early part of last week there was a foretaste of what cold weather means to patients and staff when fuel is scarce and the warming of great spaces is inefficient or impossible. In a private house where everyone is in normal health cold rooms for a day or two may be no more than a very annoying inconvenience, but in a hospital cold wards, besides adding to the difficulties of staff work of all kinds, may be a real danger to patients. So long as coal can be found to run railway services, which are but little curtailed, it is impossible to find any excuse for starving the hospitals, more especially since the production of English coal increases daily. Yet the danger of this deprivation unquestionably exists. At the best stocks of fuel are low and much of that which is obtained currently from abroad is of small calorific value, and consequently even more expensive than its inflated price attests. Many hospitals, in fact, have no stocks at all, and some are experiencing difficulty in obtaining week-to-week supplies. The Royal Infirmary at Edinburgh, for instance, which has close upon 1000 beds, finds that the foreign coal which it has been using is no longer obtainable and the supplies in hand will last little more than three weeks. Failing replenishment of the cellars it may be necessary to close wards, but an official warning to this effect has already produced some handsome offers. This may be an extreme case, since the principal hospitals of Cardiff, Manchester, and Birmingham have none of them had any real difficulty in getting coal, though it has been more expensive and in some cases of poor quality. But the general outlook is not reassuring. In London, so far, difficulties have been surmounted with fair success, and it is satisfactory to know that at the London Hospital, the largest of the metropolitan institutions, the position is much less alarming than would appear from erroneous statements in daily newspapers. Its demands are necessarily large—150 tons of fuel are required every week of which 130 are consumed by central heating—but supplies are coming in freely, the central controlling authorities having given all possible help. At St. Bartholomew's a long stoppage was anticipated and careful preparations were early made to meet the difficulties that were foreseen. Much larger stocks were laid in than is usual at that period of the year, but they are now rapidly diminishing, and a few days of really cold weather would deplete them very seriously. The existing supplies, consisting largely of foreign coal, may last for five or six weeks, but the governors are anxiously considering methods of replenishment against the days, now not far distant, when the full winter consumption will have to be provided for. Guy's Hospital generates its own electricity, and its fuel requirements are consequently large. It has no stocks to fall back upon, but current supplies have, so far, been sufficient for all purposes. Middlesex Hospital is fortunate enough to have fairly large stocks still in hand, and is able to keep its central heating system fully at work. There is consequently little cause for anxiety so long as the mild weather continues. St. George's, on the other hand, has no reserves and only foreign coal can be obtained. Both house and steam coal are costing 77*s.* per ton, and between £120 and £130 a week beyond the normal is being spent on fuel. Stocks at King's College Hospital have run very low, but what may be called domestic supplies are still being received in sufficient quantity. The most serious difficulty arises in relation to the central heating and

electric services for which fuel can no longer be obtained in adequate quantity. This hospital also generates its own electricity for all purposes, including the very important ones of massage and X ray work. The activities of these departments are consequently threatened, though they have so far not actually been interfered with. Owing to inadequate heating during the cold snap of the early part of last week, the children's wards were so much cooled that all the cots had to be placed as near as possible to open fires. Westminster Hospital's stocks were exhausted a short time ago, and it is now dependent upon its weekly allowance. That allowance has not been reduced so far as the hospital itself is concerned, but the medical school and the nurses' home are severely restricted. St. Thomas's, which uses oil fuel, is unaffected. Charing Cross burns coke only for its central heating, and is just able to manage, though full supplies are unattainable.

The troubles of the hospitals in consequence of the strike are obviously not confined to the difficulty of obtaining fuel. There are serious economic results also. Not only are coal and coke at more than famine prices, but such services as gas, electricity, and water are costing or soon will cost more. This means a heavy increase in current expenditure in directions where it is hardly possible to economise appreciably. Moreover, in many cases income has fallen heavily, especially in places where contributory schemes are in operation. Cessation of wages implies cessation of the workman's 1*d.* in the £, and his employer's supplementary payment. The voluntary hospitals are thus more than ever dependent upon the general prosperity of the country. Money will no doubt be found somehow to pay for fuel, the cost of which is not only excessive but is suspected of being unjustifiable. But the difficulty of obtaining heating material may yet be greater than that of raising money, hard as that is. Clearly the matter cannot be left at hazard. Power and light are among the first essentials for the continuance of hospital work, and precautions must be taken against that work being interfered with whilst fuel is available for less important services.

MEASUREMENT OF MOVEMENT IN JOINTS.

IT has been said with some truth that science is measurement, and if surgery aspires to rise above the status of handicraft implied by the etymology of its name it must resort to the use of instruments of precision. The necessity for this has been felt by a number of surgeons, and there is no lack of elaborately constructed instruments for the exact measurement of the deformities with which the human body may be afflicted. Unfortunately the data, the fixed points from which measurements are made, are in general ill-defined. If it is difficult in the bare skeleton to mark out the exact axis of one of the long bones, it is still more difficult to do so in the living body, when the observer is separated from his data by often voluminous soft parts. For these reasons it has seemed to us that elaborate and delicate instruments are unnecessary, for measurements can only be approximate and there must be a wide margin of error allowed. Prof. A. P. Ashhurst, of Philadelphia, has recently published a paper [1] on the Motions of the Larger Joints, which is not, as might be supposed, a dissertation on the mechanism and action of joints, but on a less ambitious scale it is an attempt to lay down some rules for the measurement of the range of motion in these joints in health and disease. Although he does not describe his apparatus, we are able to gather from the illustrations and the text that Prof. Ashhurst employs generally a simple goniometer. The carpenter's 2-foot rule with angle-plate, which is sold by all tool-dealers, is the simplest form of this, and has been found quite accurate enough by some surgeons in this country. The only other instrument mentioned in the article is a "pronometer." This has nothing to do with pronouns and grammar, but appears to be an instrument intended to register the rotary movement of the forearm, including, of course, supination as well as pronation. As there is no description of this machine and the illustrations do not show its construction, the reader is unable to judge of its efficacy a priori or to test it for himself. Measurements of the angle formed between two long bones, such as the femur and the tibia when the knee is bent, is comparatively easy, but when we come to deal with a joint of which one component is an irregularly shaped mass such as the os innominatum or the shoulder-blade, the difficulty of defining the axis of either of the latter is very great. Prof. Ashhurst makes no attempt at instrumental mensuration in these two cases, but relies upon a rough estimate by the eye alone, after pointing out the fallacies which should be avoided. As far as it goes this article may be useful, for it is a good thing to reiterate truths and illustrate them by clear diagrammatic drawings, although they may be commonplaces to orthopædic surgeons.

THE ACTION OF EMETINE IN AMŒBIC DYSENTERY.

SINCE W. C. Boeck and J. Drbohlav [1] showed that it is comparatively easy to cultivate *Entamœba histolytica* in test-tubes, the scope of clinical and epidemiological investigation of amœbiasis has been much enlarged and the experimental situation has completely changed. J. H. St. John [2] has recently shown the value of cultural methods in the diagnosis of doubtful cases and other workers have thrown new light on the incidence of amœbiasis in man. It has often been observed that in temperate zones there are large numbers of carriers of *E. histolytica* who have no symptoms, and it is said that there are nearly 2 million cyst-passers in England; yet only one or two autochthonous cases of amœbic dysentery are reported each year, and the question is often asked why the entamœba should cause dysentery amongst infested persons in the tropics but not amongst those in temperate zones. E. Brumpt [3] has used cultural methods to investigate a new species, *Entamœba dispar*, described by him in 1925, and suggests that the widespread four-nucleated-cyst amœba is wrongly regarded as *histolytica*. It should, he thinks, be classified as *E. dispar*, and is perhaps not pathogenic at all.

Whilst morphological investigations are of interest, the value of cultural methods is equally apparent when it comes to testing the value of amœbicidal drugs. It is accepted that emetine is a specific therapeutic agent in amœbic dysentery, and clinically it is found that emetine and cephaeline are the only alkaloids of ipecacuanha which have curative properties in this disease. Experiments on their action in vitro, however, have by no means borne out this clinical fact, and to explain the discrepancy it has been suggested that emetine does not act directly on the parasites and that the host plays a large part in the cure. In an important paper published recently C. Dobell and P. P. Laidlaw [4] attribute the divergence of results to the inherent error of comparing in vitro experiments, lasting only a few hours, with a therapeutic action spread over many days. They have now studied the action of ipecacuanha alkaloids on *E. histolytica* in culture and were able to improve on the original method of Boeck and Drbohlav and to get rich cultures of amœbæ, growing with great regularity. They could thus expose the amœbæ to various concentrations of ipecacuanha alkaloids for as long as was desired, at the same time being sure that their control cultures, without alkaloid, would multiply throughout the

[3] Bulletin Médical, 1926, xl., No. 5.
[4] Parasitology, June, 1926.

course of the experiments. Culture tubes inoculated with the amœba were incubated at 37° C. for two to three days, and results at the end of 48 hours were usually decisive. Earlier examinations gave misleading results. The experiments made it clear that 1/50,000 is the highest concentration of emetine that *E. histolytica* will tolerate for more than a short time. The amœbæ might live and move actively for many hours in 1/1000 concentration of emetine, but they did not multiply and the cultures soon died out. In 1/200,000 they grew well and multiplied as actively as in the control tubes. The threshold value of emetine was therefore 1/50,000 dilution. Cephaeline was found to be definitely more toxic than emetine for *E. histolytica*, but the other ipecacuanha alkaloids and derivatives, in concentrations lower than 1/1000, invariably gave cultures as rich as the controls. Quinine, tested by this new technique, in concentration lower than 1/1000, also gave cultures of *histolytica* as rich as in the controls. Stovarsol was found to be without effect in dilution of 1/20,000 or less, but had a slow poisonous action in stronger solutions; emetine, under these experimental conditions, is thus shown to be ten times more toxic than stovarsol for this amœba. Similar culture-test comparisons showed that, in vitro, emetine and cephaeline were 50 times more toxic to *E. histolytica* than were any of the other ipecacuanha alkaloids. There thus appears to be a close parallel between the actions of the various ipecacuanha alkaloids on cultures of *E. histolytica* in vitro and their several therapeutic effects in human infections with that amœba. Dobell and Laidlaw consider that their experiments show that doses of emetine and other alkaloids needed to kill *E. histolytica* immediately bear no apparent relation to the minimal doses of the same substances which are eventually lethal if maintained for a period of days. Exactly how weak solutions of emetine act on *E. histolytica* is hard to determine. The poisoning process—whatever it be—is slow, the alkaloid operating and producing its ultimate effect in a concentration far below that required to kill the parasites immediately. A very small amount of emetine, if constantly present in the intestine for days or weeks, would probably suffice to make life therein impossible for *E. histolytica*, though not for *E. coli*. Some human beings infected with *histolytica* appear to be incurable by emetine, however administered, and to explain this the existence of emetine-resistant strains of the parasite has been postulated. Dobell and Laidlaw, however, found it impossible experimentally to obtain or produce a strain of *histolytica* resistant to emetine, and suggest that these cases may be incurable because, like the cat, these individuals excrete the drug rapidly in the urine, so that little or none of it reaches the colon. Comparative analyses of urine in different cases would settle the matter. They conclude finally that the curative effects of emetine in human amœbic dysentery are best explained as a result of the direct lethal action of the alkaloid on *E. histolytica*.

The authors are to be congratulated on a valuable investigation. Their results have a wide application, for, as with amœbæ so with trypanosomes and spirochætes, it is clearly not sufficient to expose parasites to a given drug for a few minutes or a few hours, or to ascertain what concentration of the drug is instantaneously fatal. Before the possibility of direct action can be excluded, the effects of prolonged exposure to concentrations which do not kill immediately must be determined. The clinician will note, however, that these are conclusions based mainly on results of in vitro experiments and that a highly organic medium (horse serum and egg-white) was in fact incubated with the drug tested. He will think of the apparently magic—because very rapid—result of one or two gr. i. injections of emetine in severe cases of amœbic dysentery, and question if in so short a time and with so few doses a concentration of emetine greater than 1/50,000 has appeared in the colon. If no higher concentration is reached, then the direct action of emetine on the parasites in the intestine must be far more rapid than in the experimenter's test-tube.

Many interesting papers on amœbiasis, including some of those to which we have referred, are well summarised in the current *Tropical Diseases Bulletin* (September, 1926).

BATHING AND AURAL DISEASE.

THE bathing season just over has produced the usual crop of trouble in the ears of bathers; and it may be useful to examine briefly the causation and possible prevention of aural diseases due to bathing while their occurrence is still fresh in the minds of practitioners. Water can reach the ear and produce harmful effects either through the external auditory meatus or by way of the Eustachian tube. Water getting into the external ear produces a disagreeable sensation, as everybody knows from experience, but quickly runs out again from a clean and healthy meatus and, ordinarily, produces no further trouble. If, however, the ear contains much cerumen, this imbibes the moisture, swells up and blocks the canal; "water in the ear" which persists long enough for advice to be sought is nearly always due to cerumen and can usually be cured by its removal. The pressure of the swollen wax and the retention of moisture readily produce a dermatitis of the canal, and this is the usual cause of an external otitis in bathers; those with excessive secretion of cerumen should have it removed before their seaside holiday. In addition, people who have a tendency to eczema of the meatus often suffer an exacerbation of their trouble if they allow water to get into the ears, and whilst to some salt water seems to be more irritating than fresh, the water of public swimming-baths is apt to be heavily infected with micro-organisms. Unskilful diving from a height may cause rupture of the drum by mechanical force; but in general it can be said that the occasional entry of water into a healthy meatus is harmless, as is evident from the comparative rarity of trouble among innumerable bathers. All the same, as Mr. Walter Edmunds pointed out some time ago,[1] mammals, such as the water-shrew and seal, which have reverted to an aquatic existence, possess a mechanism for closing the meatus, the seal being also able to close its nostrils when submerged. The commonest cause of serious ear-disease from bathing is the entrance of water into an old, often dry and quiescent, perforation of the drum; and this may produce a very severe suppuration with all its attendant complications. Patients with a perforated drum should never be allowed to bathe without a completely efficient means of preventing the entry of water into the ear. Ordinary cotton-wool is useless; sheep's wool, being greasy and not hygroscopic, is better; a properly fitting rubber plug coated with vaseline is fairly reliable, but most satisfactory of all is a plugging material made of wax or plasticine mixed with fibre, which may be had from several instrument makers. A rubber bathing cap with ear-flaps should be worn over any plug. There remains, however, the second route of infection. People may develop otitis media after bathing though their drums and canals are perfectly healthy, and this is due to the entrance of water into the tympanum through the Eustachian tube, the inflammation varying from a mild tubal catarrh to severe otitis and mastoiditis. The chief factors which favour entry of water into the tubes are violent blowing of the nose after swimming, and swallowing whilst under water. Dr. George B. McAuliffe, of New York,[2] recently sent out a questionnaire to a number of prominent amateur swimmers of the New York Athletic Club, in an attempt to elicit why it is that this accident only occasionally happens, and how it is that water gets into the ears. He got replies from 12 swimmers of from 5 to 39 years' experience, and the answers were very various; only one thought diving injurious,

[1] THE LANCET, 1924, i., 1081.
[2] Medical Journal and Record, Sept. 15th, 1926.

and two of the three who blow the nose after emerging had had ear inflammations. There was an impression that salt water was more injurious than fresh, probably because it encouraged nasal secretion and blowing of the nose. Dr. McAuliffe's conclusions seem sound—namely, that in a healthy ear the use of plugs are unnecessary; that the only time that a plug is needed is when there is an open perforation or when the skin of the canal is irritated by the water; that bathers should not swallow while swimming, and that they should let the water drain from the nose and avoid blowing on coming out of the water. If blowing the nose and swallowing are avoided, no ear complication will occur.

THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

SINCE the establishment of the Irish Free State many of the chartered corporations in Ireland have found that their charters have become in some points defective. The Royal College of Physicians, for example, has found itself without visitors, since the public officials designated in its charters no longer exist. A more serious disability has been the suspension of its power to make new, or alter old, by-laws. For a by-law of the College to become effective it had to receive the approval of the Lord Lieutenant in Council. The Lord Lieutenants to the Privy Council disappeared when the Free State came into being, and while some of their powers were transferred to other bodies, in regard to others no such arrangement was made. The result, as far as the College of Physicians was concerned, was that there was no machinery by which it could make or amend by-laws, and several intended amendments have been held up for some years past. An Act for the amendment of charters passed the Oireachtas, however, a few months ago, which remedied this defect, and suitable action has now been taken. The Minister for Justice, as empowered by the Act, has issued an Order making the necessary amendments in the Charter of the College. The Chief Justice and the President of the High Court of the Irish Free State are nominated as visitors, and the Minister for Justice is himself constituted the approving authority for by-laws in place of the Lord Lieutenant in Council. In future, therefore, the College will be free, with the approval of the Minister, to make such by-laws as it thinks fit. The first change, which has already passed the College, will be to widen the scope of the examination for membership.

ENCEPHALO-MYELITIS FOLLOWING VACCINATION.

WHEN reviewing recently [1] a series of cases of encephalo-myelitis in which, according to Prof. H. M. Turnbull and Prof. James McIntosh, vaccination was a definite causal factor, we had occasion to refer to cases occurring in Holland during 1925. Further allusion to these cases appears [2] in an article by Dr. F. S. van Bouwdyk Bastianse, of The Hague, in its clinical and histological aspects in collaboration with Dr. J. P. Bijl, of Utrecht, who records his experiments on animals. Dr. T. T. Terburgh, of The Hague, supplies the epidemiological data. Their observations are based on their experience in Holland where from Jan. 1st, 1924, to July 1st, 1925, 35 cases, of which 15 were fatal, occurred of encephalitis following vaccination after an interval usually of 10 to 13 days. The cases were chiefly met with in small communes, sometimes closely adjacent to one another, and more than one case was often observed at one time in the same commune. Most of the cases were notified in March, when epidemic encephalitis was more prevalent than in the other months of the year. The vaccine used for the children who developed encephalitis came from three different institutions, and 12 calves served to provide the lymph. Dr. Terburgh found that encephalitis could be produced by inoculating the brains of rabbits with vaccine lymph and that in the brains of these animals a virus could be demonstrated which was apparently identical with Levaditi's neuro-vaccine. No infective agent could be found in the cerebro-spinal fluid of the affected children during life or after death. The writers' conclusions are as follows: 1. It is impossible to deny a connexion between vaccination and the encephalitis which follows it. 2. Post-vaccinal encephalitis is probably caused by an ultra-virus. 3. It is very improbable that post-vaccinal encephalitis is caused by the direct or exclusive action of vaccine lymph—there must be some unknown contributory factor. 4. It is most likely that the process of vaccination has given rise to the activation of a latent virus. 5. The supposition that this virus is the virus of epidemic encephalitis or one closely related to it offers the readiest explanation of the clinical and histological picture as well as of the epidemiological facts. The proof of the last two conclusions, however, is not yet forthcoming, and we are more inclined to accept the views of Turnbull and McIntosh.

PROFESSOR SCHMIEGELOW.

Dr. Ernst Schmiegelow, of Copenhagen, celebrates his seventieth birthday on Oct. 13th, when he retires from active service as chief of the Oto-laryngological Clinic at the Rigshospital. His friends in many countries are marking the occasion by presenting to the clinic a medallion portrait in bronze of their professor. The Royal Society of Medicine will be represented by Sir StClair Thomson, a past-president of that body, who will contribute a communication at a meeting of the Danish Oto-laryngological Society, to be held on Oct. 12th. Addresses will also be given by Prof. H. Burger (Amsterdam) and Prof. Carl von Eicken (Berlin), and other European leaders propose to unite in doing honour to the doyen of Danish oto-laryngology. Prof. Schmiegelow, who was a pioneer in his subject, studied for a time at the London Throat Hospital, and has been a frequent visitor to this country, where he has many admirers and friends.

THE LIVERPOOL HOSPITAL CONTRIBUTORY SCHEME.

AT a public meeting held in the Liverpool Town Hall on Sept. 27th a scheme of voluntary workmen's contributions towards the support of hospitals was adopted with practical unanimity. This scheme provides for the amalgamation of the existing Hospital Saturday and Sunday Funds and for the formation of a Liverpool Voluntary Hospitals' Council, to which shall be appointed an organising secretary of high standing—a whole-time official. The new council proposes to organise collections amongst workmen on the basis of 1*d.* per £ of wages per week, to which it is hoped that employers will add one-third more. The money thus collected will be handed over in proportionate sums to the various voluntary hospitals and convalescent homes in the district, with whom it is stated the entire responsibility as to its expenditure will rest. No charge will be made to the necessitous poor, but all other non-contributors to the scheme will be asked to pay towards their maintenance in hospital. Contributors and their dependents will be admitted and treated free. Judging by the success of the Sheffield scheme, the amount raised should be ample to solve all the financial problems of these institutions if it were not for the casual nature of a large part of the employment in Liverpool. A meeting of the new council will be summoned at an early date.

The scheme introduces a number of problems of vital importance to the medical profession in Liverpool, where there exists a Hospital Staffs Association in whose hands local interests may safely be left. In voluntary hospital administration elsewhere the principle holds that payment of a contribution does not of itself carry the right to the services of the local

hospital, which must depend in the final issue upon the needs of each case and its relative urgency. Assuming this principle to be fully upheld in the Liverpool scheme, the contributions might then be regarded as in the nature of voluntary subscriptions to a charity, the essential character of the Liverpool hospitals remaining unchanged. But it appears that distinction is to be made between contributors and non-contributors; in other words, the contributor is to receive a quid pro quo and his contribution becomes an insurance premium. It will be for the medical staffs of the Liverpool hospitals to adopt an attitude, at once humane and logical, to the continuously growing demand on their highly skilled service.

TRANSLUCENCY OF THE CORNEA.

OPACITY of the cornea is a common cause of impaired vision in every degree from the slightest defect of sight to complete blindness. It is, therefore, important to understand what causes corneal opacities and how far they are curable. The anatomical structure of the cornea consists of parallel fibrous lamellæ bounded on the outside by an epithelium and on the inner side by an endothelium, which normally protects it from infiltration by the aqueous humour. Slight opacities may be caused by injuries to the epithelium but this is soon regenerated and complete transparency may be restored. Infiltration of fluid into the substantia propria may be due to pressure as in glaucoma or to disease such as interstitial keratitis. In this case the infiltrating fluid contains cells and the opacity may be extreme. Nevertheless the infiltration may eventually be completely or almost completely absorbed and the transparency of the cornea restored. A third type of corneal opacity occurs from actual injury of the fibres of the substantia propria such as results from a deep ulcer or a wound. Here the opacity may be partly due to infiltration and, in so far as this is the case, treatment by such things as stimulating ointments may be partially effective, but there remain the cases in which there is actual replacement of the normal fibres of the cornea by scar tissue. In the worst cases such as follow a severe ophthalmia neonatorum the whole cornea may be converted into scar tissue, and in these no treatment which has hitherto been devised can possibly restore the transparency. A suggestion has been made by Dr. S. G. Moore, who has seen the wonderful specimens prepared by Prof. Spalteholz, of Leipzig, in which the tissues are rendered so translucent that, for example, injected arteries are readily seen in relief in transmitted light—that this process, applied to living tissues, might restore some measure of useful vision in cases of blindness due to opacity of the cornea. Dr. Moore believes this process to be secret, but reference to Bulletin No. V. (p. 41) of the International Association of Medical Museums shows that it consists in impregnating the tissues with a fluid of suitable refractive index, composed of oil of wintergreen and benzyl benzoate. Although the application of methods of this kind to living tissues was foreshadowed by Mr. H. G. Wells in his "Invisible Man," it can hardly be expected that living protoplasm should survive so gross an insult to its normal refractive index.

OTAGO MEDICAL SCHOOL.

AN experiment in clinical instruction is about to be made in Otago. The plan of university education in New Zealand is adapted to its topographical needs and differs from that elsewhere. The University of New Zealand is an examining and degree-granting body, with headquarters at Wellington; it prescribes courses and appoints examiners, but it undertakes no teaching. All instruction is carried on in the four constituent colleges—Auckland University College; Victoria College, Wellington; Canterbury College, Christchurch; and the University of Otago, Dunedin. The early settlers of Otago, in good Scots fashion, established their University before that of New Zealand was founded, and Otago has consequently retained the title of University, though it does not now grant degrees. Arts and science, and some other subjects, can be studied at any of the centres, but the professional faculties are concentrated at single colleges; engineering, for instance, at Canterbury College, and medicine at Otago University. Some years ago the Dean of the Otago Medical School put forward a proposal that the medical curriculum should be extended from five years to six, which had already been done, either avowedly or in practice, in various overseas schools. The proposal aroused considerable discussion, and the Senate of the University of New Zealand decided to refer the question to the New Zealand Branch of the British Medical Association for an opinion. A good many members were averse from the extension, and there was a general feeling that if a year were added to the course it should be a "clinical" year and also that facilities should be afforded for spending it in the public hospitals of other centres of the Dominion—namely, Auckland, Wellington, and Christchurch, and not wholly in Dunedin. This proposal, writes our New Zealand correspondent, could not be complied with in its entirety. There was never any intention of leaving the curriculum as it was, and merely adding another year during which students should kick their heels until they had put in the necessary terms to allow them to sit the final examination. One of the additional terms was required for the "intermediate" subjects, chemistry, physics, and biology, and one for the "first professional" subjects, anatomy and physiology, leaving only one term for additional clinical study. However three complete years, or nine terms, are now available for clinical work, and by the new scheme a student may elect to spend one, two, or three terms of the final year in the hospital of another centre, provided an adequate syllabus has been submitted by the medical staff of the hospital concerned to the Faculty of Medicine in Dunedin; all the hospitals have now submitted schemes, and one, at least, is providing quarters for the students. This public-spirited action on the part of the hospital staffs concerned will mean a considerable addition to their work. By this arrangement the students' clinical experience will be undoubtedly much increased, since the whole facilities of a considerable hospital will be available for a small group who have already had two years' ward-training. The result will be watched with interest by other schools.

THE DÜSSELDORF CONFERENCE.

THE eighty-ninth conference of Naturforscher and Ärzte at Düsseldorf from Sept. 19th to 26th was divided into 34 sections and attended by well over 8000 scientists and medical men from Germany and German-speaking countries, so that its mere size gave rise to difficulties in organisation, while the large proportion of natural scientists resulted in the treatment of medical subjects on lines suitable for the advanced medical student. But these difficulties were largely surmounted by Dr. Arthur Schlossman and Frl. Dr. Marta Fraenkel, who were responsible for the arrangements. The outstanding feature of the conference was a series of communications by Prof. P. Mühlens (Hamburg), Prof. F. Sioli (Düsseldorf), Drs. Hörlein and Röhl (Elberfeld) on a new synthetic remedy for malaria, to which the name plasmochin had been given. Tested first by Röhl on canaries infected with bird malaria, it was then administered by Sioli to paralytics under treatment by malaria, in whom repeated doses of 0·2 g. proved uniformly effective. Mühlens and his colleagues began to use the drug at the Hamburg Tropical Diseases Institute in August, 1925, and 134 cases from all parts of the world have now been treated with careful daily control of the blood. The preparation is almost tasteless and for this reason especially useful for children. Four to six weeks' treatment are required. Fever and parasites disappeared in a few days and relapses were less numerous than when quinine was

used. Above all, the new preparation was found to destroy the crescentic sexual forms which were banished from the circulation within five to seven days, while early treatment with plasmochin effectually prevented their appearance. The story of this successful search for a plasmodicidal agent was the sequel to an admirable account by Prof. Nocht (Hamburg) on the previous day of the various recent essays in chemotherapy, including the discovery of germanin (Bayer 205) which with its single haptophore group held its victims fast, like a limed twig, so that they fell a prey to their natural enemies. To English hygienists the joint meeting of the sections of hygiene and veterinary medicine was made noteworthy by the presence of Prof. Ostertag. The communication by Dr. Bahr (Copenhagen) on the endotoxin of the paratyphoid-Gaertner group rendered due credit to the work of the English bacteriologists. Prof. Miessner (Hanover) gave an account of paratyphoid and paradysentery in cattle with an important statement on paratuberculosis. Dr. Beck (Leipzig) reviewed the possibility of disease transmission by pigeons, the organism he had isolated being of the Breslau type. In another section much interest was taken in an account by Dr. P. Schwartz (Frankfort) of the effect of injuries to the skull and brain during childbirth, supported by convincing slides of morbid anatomical specimens. Hæmorrhage from the vena terminalis might account, he thought, not only for porencephaly but for the onset of hydrocephalus, syringomyelia, and even of some cases of epilepsy. During the week conducted visits were paid to the enormous Health Exhibition (Gesolei), Prof. F. Fülleborn acting as guide to the tropical diseases exhibit. The social side of the meeting was well organised, and the next conference might well attract more representatives from this country.

A LUNCHEON was given by Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, on Tuesday last, at the Hotel Victoria, S.W., to an international gathering of port medical officers, who are now in this country as guests of the Government. The presence of the visitors, followed on the terms of the new convention, agreed upon at the International Sanitary Conference, with respect to sanitary measures at ports and their international arrangement.

Obituary.

DAVID EWART, O.B.E., M.D., F.R.C.S. EDIN.

Dr. David Ewart, of Chichester, who died on Oct. 2nd, was a practitioner of high reputation in West Sussex, where he had worked for about 25 years. He was educated in New Zealand and at the University of Edinburgh where he was Grierson Bursar in pathology and bacteriology in 1898. Soon after graduating with honours in the following year he was appointed to the Chichester Infirmary, where he remained as house surgeon for two years, after which he was elected surgeon and took up practice in the district in partnership with the late Dr. Skaife. From that time onwards he steadily built up a reputation for the infirmary and for himself. He started departments for ophthalmic and aural work and undertook an ever-increasing amount of major surgery of all kinds. At the same time he built up a large private practice and was in frequent demand as a consultant and as an ophthalmic and operative surgeon. The Chichester Infirmary was enlarged and improved in 1913, being reopened by the King as the Royal West Sussex Hospital, and in this work of reconstruction Dr. Ewart played an important part. The war broke out soon afterwards and the scope of his activities was further enlarged by his appointment as surgeon to the Military Hospital of 1100 beds formed by temporary conversion of the county mental asylum; this additional heavy work put a serious strain upon his health. Dr. Ewart could not take much part in non-medical affairs in the district, but found time for service as a member of the Council of the British Medical Association, and was at one time chairman of the Dominions Committee. He also held consulting appointments at the King Edward VII. Sanatorium at Midhurst and other institutions in the neighbourhood, and in April of this year was elected chairman of the board of management of the Royal West Sussex Hospital.

Dr. Ewart leaves a widow and six children.

JAMES BARRY BALL, M.D., F.R.C.P. LOND.

Dr. Barry Ball, who died at his home in Abingdon on Oct. 2nd, was well known in London before his retirement as a specialist in diseases of the ear, nose and throat, and was appreciated as a valuable colleague and a man of high ideals. He was born at Manorhamilton in County Leitrim in 1849, and studied medicine at University College, London, qualifying in 1870. After some years of general practice in Brixton he became a member of the Royal College of Physicians in 1885, and in the same year was appointed assistant physician to the West London Hospital, which he served with zeal and devotion for a long period. In 1887 he was given charge of the throat and nose department and ten years later took over the ear department as well, shortly afterwards resigning his appointment as physician so as to give his whole attention to this special work. In 1905 he left the active medical staff and was made consulting physician and a member of the board of management, positions which he held until his death. Dr. Ball's work for other institutions was also considerable. He was consultant physician to the Hospital of SS. John and Elizabeth, lecturer to the West London Post-Graduate College, and examiner in laryngology and otology to the Royal Army Medical College. For over 20 years he was physician to the Rock Life and other assurance companies, which he served always with tact and judgment. He was also the author of a Handbook of Diseases of the Nose and Pharynx which reached a fifth edition, and made numerous contributions to Quain's "Dictionary of Medicine" and to the medical journals. Dr. Ball's work was recognised by his election as President of the Laryngological Society of London and to the Fellowship of the Royal College of Physicians. Those who enjoyed his friendship speak of his loyalty and warmth of heart, whilst those who met him casually found that a retiring manner did not always conceal unusual and welcome wit.

Dr. Ball leaves a widow and one daughter. He lost his only son in the war.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. Comdr. L. R. Warburton to be Surg. Comdr.
T. A. Cochrane to be Surg. Lt.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Lts. (D) to be Surg. Lts. (D): C. T. Pomeroy and W. E. L. Brigham.

ROYAL ARMY MEDICAL CORPS.

Maj. A. H. Heslop retires on retd. pay on account of ill-health.

REGULAR ARMY RESERVE OF OFFICERS.

Col. F. Kiddle (late R.A.M.C), having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

Lt.-Cols. L. A. Williams and G. B. Riddick, having attained the age limit of liability to recall, cease to belong to the Res. of Off.

MILITIA.

Maj. E. T. Holland retires on attaining the age limit.

TERRITORIAL ARMY.

Capt. J. Blackwood to be Maj.
Capt. (Prov.) R. M. Savege is confirmed in his rank.

ROYAL AIR FORCE.

Flying Officers B. W. Cross and J. MacConnell Kilpatrick are granted permanent commissions in their rank.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXCII.

TREATMENT OF ACUTE INTUSSUSCEPTION IN INFANTS.

THE crucial importance of early diagnosis of intussusception in infants may be gathered from operation statistics. Operation within 12 hours of onset is almost invariably successful, whereas the mortality-rate in cases left 24 hours or longer varies from 30 to 60 per cent. Every hour is thus of importance from the point of view of prognosis.

Diagnosis.

Acute intussusception occurs typically in strong healthy infants, often of the male sex, the commonest age being 4 to 8 months; there is a history of sudden onset of acute abdominal pain, occurring in spasms, shortly followed by vomiting and later by the passage of blood. Between the spasms of pain during the early stages the baby may appear perfectly healthy, and this should be remembered. Often the onset is less typical, the appearance of blood being delayed for many hours. It is in these cases that the palpation of the typical sausage-shaped tumour clinches the diagnosis, and unless this tumour is felt the diagnosis is doubtful. A thorough abdominal examination in every suspicious case is essential, and for this an anæsthetic is often required. Before giving the anæsthetic it is wise to make preparations to proceed to immediate operation should the intussusception be found, but this is not always feasible; for example, if operation entails a long journey the practitioner must make his own diagnosis before referring the child to the surgeon. The anæsthesia must be deep in order to get complete relaxation of the abdominal muscles, and the whole abdomen must be carefully and systematically palpated in order to find the tumour; this may be hidden in the region of the hepatic flexure by the liver, or at the splenic flexure if the tumour lies practically under the costal margin. Often the tumour is small and very mobile, slipping from under the examining fingers. In the absence, even under anæsthesia, of any palpable tumour, I myself do not operate. When the diagnosis is established treatment nearly always involves opening the abdomen. The only possible exception is when local conditions make surgical procedures impossible. Then, and only then, is treatment by the injection of fluids per rectum justifiable. The chief objection to this method of treatment is that it is impossible to tell whether reduction so effected is complete; during operation it is clear that it is the last inch or so which is the most difficult to reduce. However, there can be little doubt that a considerable number of intussusceptions reduce themselves and may give no further trouble, though recurrences among these cases are not uncommon.

Reduction by Operation.

Pre-operative treatment is of great importance, since these children are depleted of fluid as a result of the frequent vomiting. In every case it is wise to administer subcutaneous saline into the axillæ or loins before operating; improvement immediately follows the saline infusion. The patients should be well warmed up in bed for at least an hour, and a hypodermic injection of atropine, 1/150 gr., should be given half an hour before the anæsthetic. The operating theatre should be kept at a temperature of 75° F.; the child's limbs should be bandaged with cotton-wool, and when possible the table should be artificially heated.

Anæsthetic.—Where the child is not in good condition the anæsthetic of choice is gas and oxygen, with a minimum of ether in addition, but if this form of anæsthesia is not available ethyl chloride, followed by ether, gives almost equally good results. Anæsthesia must be deep, since should the intestines be forced out by straining, the operation not only becomes more difficult, but the shock is greater, and much time may be lost.

The *incision* depends on the site of the tumour. Where the intussusception is proximal to the splenic flexure, the muscle-splitting incision of McBurney gives ample room and can be rapidly performed. Where the tumour has passed into the descending colon this incision gives insufficient access and a vertical paramedian incision is indicated.

Operative success depends mainly on (1) rapidity, and (2) extreme gentleness in handling. The peritoneal cavity is opened and two fingers of the right hand are passed into the abdomen to seek the tumour. When it is found reduction is attained by milking it gently backwards along the colon within the abdomen, until the ileo-cæcal region is reached. Difficulty may be experienced at the two least mobile portions of the colon, the splenic flexure and the hepatic flexure, but only because they are awkward to reach and manipulate. The actual reduction gives trouble, as a rule, only in the terminal two or three inches, on account of the great swelling and œdema of the parts. At this stage the intussusception should be brought out of the abdomen and the milking process continued with great care. In a favourable case reduction can be accomplished without any damage to the peritoneum of the bowel wall. When the last portion of bowel is being reduced, the typical dimple will be seen where the intussusception commenced, generally within an inch or so of the ileo-cæcal valve. This dimple is a cup-shaped depression which should be carefully obliterated.

In some cases—generally those of long duration—the peritoneal coat of the cæcum may give way during reduction. This calamity may often be prevented by a simple manœuvre which, moreover, facilitates reduction; the tumour is surrounded by a hot moist swab and uniform pressure is exerted on it in order to reduce the œdema. When pressure has been maintained for some 30 seconds reduction is often effected easily. A tear in the peritoneal coat is not necessarily a sign of irreducibility, and unless it is obvious that reduction is going to be impossible or that the bowel is gangrenous, efforts should be continued in spite of it. It is important, however, that any tears in the large bowel should be sutured with very fine catgut, lest infection passes through the bowel wall and peritonitis ensue.

When reduction has been completed nothing further should be done. The abdomen should be rapidly closed. In children under a year it is a mistake to remove the appendix or to attempt fixation of the invariably mobile cæcum, since extra handling of the bowel in addition to the extra time required increases the risk of a fatal issue. A simple operation for reduction alone can be performed, from incision to closure, in seven minutes, and should never take more than 15 minutes in skilled hands. If the child is over a year old and is in good general condition the appendix may be rapidly removed.

Recurrence.—Since the operation of reduction does nothing to remove the conditions, whatever these may be, producing intussusception, it is curious that recurrence is so rare—about 2 per cent. in my experience. The fixation of the cæcum, while theoretically a useful procedure, does not seem to prevent recurrence of an intussusception at a later date.

Operative Technique in Irreducible Cases.

When the intussusception is irreducible the prognosis is always very grave, and it is rare for a child under a year old to survive operation.

When the intussusception is absolutely irreducible or is gangrenous the methods to be considered are: (1) Resection of the affected area with anastomosis of the bowel; (2) resection combined with temporary enterostomy to be followed later by anastomosis; (3) temporary enterostomy without resection. Several other procedures have been suggested. In my experience the only one giving satisfactory results in infancy and childhood is the first method mentioned above. Although the mortality in infants under a year is very high, this is undoubtedly the best procedure. A rapid resection between clamps should be carried

out, and, as a rule, a lateral anastomosis between ileum and transverse colon, or between two portions of ileum, is the most satisfactory way of dealing with the bowel.

Closure of the Abdomen.

When the reduction has been effected or anastomosis and resection performed, the abdomen should be closed as rapidly as possible. If the muscle-splitting incision has been used two layers of sutures are desirable, but to close the vertical paramedian incision through-and-through sutures of interrupted silkworm-gut introduced with a Doyen's handled needle should be used, the stitches being prevented from cutting too deeply by means of rubber tubing threaded on the silkworm-gut. In both cases Michel's clips are used to bring the edges of the skin into perfect apposition. A small gauze dressing is applied and is maintained in position by the application of a large oval piece of Mead's strapping. No bandage is required. The wound need not be dressed until the clips are removed on the fifth day, while the through-and-through sutures remain in for 10–12 days.

Post-operative Measures.

Post-operative measures consist chiefly in the administration of fluids and the maintenance of warmth. The child should receive subcutaneous saline four-hourly for 12 to 24 hours, and should be kept warm by means of an electric cradle in the cot. For the first few hours the foot of the bed should be raised, to mitigate collapse. The temperature should be taken three- or four-hourly as hyperpyrexia is not uncommon in the first 24 hours; if it occurs the electric lamp should, of course, be extinguished, but it is important not to bring down the child's temperature too rapidly, and unless the temperature rises higher than 104° F. no tepid sponging need be carried out. In an uncomplicated case a little sugar and water may be given by mouth after six hours; if the child is on the breast the milk should be drawn off and given in teaspoonful feeds every two hours for another 6 to 12 hours. If there is no vomiting the child may be put to the breast for five to ten minutes every three hours for the next 24 hours and given sips of water if thirsty. Thereafter normal feeding should be resumed. Aperients should be avoided for the first six days, after which a teaspoonful of castor oil may be given, provided the child is doing well. If, however, there is any sign of distension or any vomiting, a gentle rectal wash-out is preferable to the aperient.

Where resection has been carried out feeding should be commenced more gradually. It is wise to give nothing but water and albumin water for 24 to 36 hours, supplemented where necessary by subcutaneous saline. Should the abdomen become distended and vomiting recommence, the stomach should be washed out with a little sodium bicarbonate.

Post-operative Complications.—Vomiting may be troublesome for 24–36 hours, and if severe, should be treated by stomach lavage, repeated six-hourly if necessary; meantime subcutaneous glucose saline must be relied on for nourishment. *Enteritis*, sometimes occurring about the third or fourth day in an infant which has had to be suddenly weaned, is a complication to be dreaded. An immediate dose of castor oil is indicated, followed by routine medical methods, and very careful nursing may save the child. *Obstruction* is rare, except where due to a temporary paresis of bowel, which responds better to stomach and colon lavage than to stimulants such as pituitrin. When obstruction is due to peritonitis the prognosis is hopeless. *Recurrence* during convalescence calls for immediate operation, of which the result is often successful. Recurrence at a later date is nearly always diagnosed immediately by the parents, and the patients generally do well after a second operation.

GERTRUDE HERZFELD, M.B., F.R.C.S. Edin.,
Surgeon to the Royal Edinburgh Hospital for Sick Children; Lecturer in Diseases of Children, University of Edinburgh.

Special Articles.

THE ST. MARY'S POST-GRADUATE COURSE.

THE post-graduate course held for the fifth year in succession at St. Mary's Hospital, London, over the first October week-end was the most successful of the series, many practitioners availing themselves of the opportunity offered without fee to refresh their knowledge in some direction or other of modern medicine. The demonstrations of cases by Dr. C. M. Wilson and Mr. R. M. Handfield-Jones on Sunday morning do not lend themselves to brief notice, but of the ten more formal lectures an epitome of three may serve to indicate the practical and useful scope of the meeting.

The Scope of Cæsarean Section.

On Oct. 2nd, the first day of the meeting, Mr. Aleck Bourne considered the proper place of Cæsarean section as a means of delivery in abnormal labour. The first, and still the chief indication, is contracted pelvis, and to-day, after much clinical experience, most obstetricians agree that there are very few other abnormalities which are properly so treated. The deliberate operation should be done for contracted pelvis if, before the thirty-sixth week of pregnancy, the head cannot be made to enter the brim of the pelvis. Induction of labour is a better method for the minor degrees of contraction which would cause difficult labour at term. The great disagreement, however, ranges round the question of the operation after attempts at vaginal delivery have failed—in other words, "the failed forceps case." It is very commonly done for this condition, and justification is sought in the occasional escape of the mother from the fatal termination, but an experience based on two or three cases is of no value. Only by the consideration of a large number can an opinion properly be formed. The pressing dangers are an immediate shock, caused by a severe operation done for one who is already exhausted; later, sepsis, causing fatal peritonitis or sloughing of the abdominal wound and uterine fistula, and, in the future, risk of rupture of the uterus in a subsequent pregnancy or labour due to an imperfect union of the infected muscle walls of the uterus. Now the average mortality of the operation done before labour is about 1·5 per cent., while after attempts at forceps delivery it rises to 27 per cent. (Kerr and Holland's collection). This very sharp rise in the death-rate shows that the danger is very great, and should only be faced under exceptional conditions. Nor can we find justification for Cæsarean section, after failure with forceps, by a consideration of the fœtal results. Of 100 babies subjected to the fruitless stress of forceps and later delivered by the abdomen, nearly half did not leave the hospital alive, and of those who do survive there is an uncertain number who suffer from impaired and backward development throughout childhood. This means that the mother is being subjected to a risk of 27 per cent., and a much greater chance of subsequent ill-health due to uterine adhesions, fistula, &c., or even later rupture of the uterus, for the sake of a baby that has barely one chance in two of survival. Only rarely will forceps fail to deliver, given the essential lapse of sufficient time for moulding, but when they do fail the alternative is not Cæsarean section but the perforator. Central placenta prævia is probably the next commonest indication. The lateral and many marginal cases can be well and safely treated by pulling down a leg or rupturing the membranes, with or without plugging. Even central placenta prævia should only be operated on if the mother is in good general condition. To deliver by the abdomen when the mother is already blanched is to invite disaster. Such cases should be treated by the most conservative vaginal methods. If,

however, the condition of both mother and baby is good and the patient is first seen before or early in labour, then Cæsarean section will probably save both mother and child. Obstructing pelvic tumours compel abdominal delivery if they are actually incarcerated in the pelvis and cannot be pushed up. Certain malpresentations, such as the brow, the shoulder, or even the breech in an elderly primigravida may be treated by Cæsarean section, especially if there has been a previous stillbirth. On the other hand, Mr. Bourne concluded, the operation is a dangerous method of delivery for eclampsia when compared with conservative vaginal methods, inasmuch as it doubles the mortality, whether the case is mild or severe when first seen.

The Rheumatic Problem in Children.

On Oct. 4th Dr. Reginald Miller, dealing with rheumatic children, referred briefly to the magnitude of the problem considered as a national health question, and discussed some of the chief difficulties in dealing with the disease on a large scale and the possible lines of their solution. First, as regards the causation of the disease, hereditary factors are not of such moment as environmental factors such as climate, poverty, damp houses, industrialism, exposure to wet during attendance at school. So far as these factors can be controlled they must be left to the public health and school services. Secondly arises the question of tonsillectomy. Nearly every rheumatic child has chronic tonsillitis, and to leave such tonsils untreated is to fail to give the child its best chance. Early and complete tonsillectomy gives considerable protection against heart disease, though not apparently against uncomplicated chorea. Third is the difficult matter of the development of heart disease. This often occurs while the child is apparently well and attending no doctor. Practitioners and hospitals can do something by instructing parents in the dangers of the disease, but to meet the difficulty properly some form of supervision of the children must be evolved. Parents must be taught to bring their children for examination every few weeks whether they appear ill or not, just as in cases of epilepsy or syphilis. In hospital practice it would be easy to establish a "rheumatism bureau," the children being listed and sent for to be seen by their respective physicians periodically. A better plan would be to establish a "rheumatism supervisory centre," open once a week, where cases can be sent for periodic examination while they are apparently well and arrangements are made in writing for the child to go back at once to its own doctor should acute symptoms supervene. With this system a good deal of useful research work could be undertaken. In dealing on a large scale with the problem of rheumatism and heart disease it is to be hoped that the mistakes made in the antituberculosis campaign may be avoided. We do not, said Dr. Miller, want the so-called expert and the treatment clinic. More beds are needed for children with damaged hearts to obtain the prolonged modified rest so necessary for them; these might be provided in special wards of convalescent homes or special hospitals in the country, provision being made for education and for the easy transfer of cases between hospitals and rest-homes.

Use of Radium in Gynæcology.

On Oct. 4th Mr. T. G. Stevens said that at present radium was chiefly employed in gynæcology in the treatment of carcinoma of the cervix, carcinoma of the vagina, and the severe hæmorrhages of chronic metritis. The attitude of most surgeons, he said, was that in carcinoma of the cervix radium applications should be reserved for clinically inoperable or borderline cases, in the belief that extended panhysterectomy gave better results in operable cases. There were no data at present available to prove this belief, as no large series of operable cases had been treated by radium alone, and it was quite possible that with increasing knowledge of the right technique the results of radium treatment alone in operable cases would prove to be as good as or better than those obtained by operative means. The method of application, said Mr. Stevens, varied in different clinics; in some of them concentrated doses were applied inside the uterus and in the vagina by means of platinum tubes containing 50 or 25 mg. of radium element; in others the maximum dose determined upon was applied by means of needles containing small amounts of radium element spread out around the growth by circular implantations. At St. Mary's Hospital each of the needles used contained 2 mg. of radium element; but in France the tendency was to employ even smaller doses (1 mg.), using a large number of needles and leaving them in situ for a correspondingly longer time. There was not at present sufficient evidence to show which of these two methods gave the better results. The dose given in any case was computed by multiplying the number of milligrammes of radium element used by the number of hours of the application. In general it might be said that 2400 mg. hours was the usual dose, but in the case of large growths this might be considerably increased. The first dose might be followed by a second after three weeks had elapsed, using a similar amount of radium, but after this no further treatment should be given for six months; no benefit appeared to result from any further application, and in some cases, indeed, it seemed to have been harmful. Before applying radium, continued Mr. Stevens, it was most important that the growth should be disinfected as far as possible. A useful method was to pack the vagina with a strip of gauze soaked in 10 per cent. Milton solution for 24 hours, repeating the packing twice, and then to swab the growth all over with flavine solution just before applying the radium. It was better not to curette the growth, as this appeared to open up avenues for infection and dissemination. When concentrated tubes were used, one should be placed in the uterine cavity well above the growth, and others should be applied accurately against the vaginal surface of the growth. The latter were often difficult to keep in place, and sometimes must be sutured to the vaginal roof to ensure immobility. The vagina must be packed with gauze soaked in flavine, taking care to push the rectum as far away from the radium tubes as possible with the gauze pack. This was done to protect the very sensitive rectal mucosa from the radium rays, and to prevent fistula formation. Whilst the bladder seemed to be much more resistant to the rays than the rectum, it also could be protected by carefully applied gauze packing. In most cases it was advisable to suture the labia together, to prevent any extrusion of the gauze pack, and to insert a self-retaining catheter into the bladder so as to avoid any disturbance due to micturition. The same technique was used in the treatment of carcinoma of the vagina. Concentrated tubes were nearly always used, and were generally sutured in direct apposition to the growth. In chronic metritis, said Mr. Stevens, in conclusion, radium was at the present time the most useful means of treatment. The result aimed at was complete cessation of menstruation, which formerly could not be secured except by hysterectomy or tedious X ray treatment. Chronic metritis in women over 40 usually caused very severe and prolonged menstrual losses, and these could be completely stopped by a single application of radium—100 mg. for 24 hours placed in the uterine cavity after dilatation. Curettage was usually done in such cases to eliminate the possibility of carcinoma of the body of the uterus.

ORTHOPÆDICS AT BIRMINGHAM.—The first annual report of the Birmingham Cripples' Union and Royal Orthopædic and Spinal Hospital, as an amalgamated institution, records an enormous increase in the work and heavy unsatisfied demands. It is intended to transfer all bed cases to an open-air suburban hospital, the site for which has been given by Mrs. George Cadbury. The full scheme contemplates a hospital of 300 beds which will serve as the orthopædic centre for Birmingham and the Midlands.

THE TWELFTH INTERNATIONAL SANITARY CONFERENCE.

A NEW CONVENTION.

THE twelfth of a series of International Sanitary Conferences which have regulated quarantine procedure, at first in Europe and later throughout the world, was convened in Paris on May 9th of this year, and resulted in the signature of the Sixth International Sanitary Convention.

The first of these conferences met at Paris in 1854, and those succeeding it have each in turn shown a widening view of quarantine action and have reflected the steady growth of knowledge. The earlier conferences were summoned to protect Europe from plague and cholera introduced from other continents, but the tendency has been more and more to look on the world as an organic whole, each part of which is to be guarded by wise and suitable quarantine precautions against the spread of epidemics. At this last conference 70 different nations and territories were represented, as compared with 42 in 1911 and 23 in 1903.

After the conclusion of peace the Office International d'Hygiène Publique, which is the body entrusted by international agreement (Rome Accord 1907) with the duty "of suggesting modifications that it might be advantageous to make to the Conventions" undertook a draft revision of the 1912 Convention. This revision was rendered necessary by the results of scientific research, by the lessons learnt in the war and in epidemics after it, and by alterations of political boundaries and conditions. In 1922 a draft revision was completed and delivered to the French Government for communication to the Powers. In February, 1925, a final revision was ready. It was on this draft that the new Convention was based, and it was owing to this preliminary work that the conference was able to finish its work in a relatively short time, in spite of the wide and various alterations proposed.

The conference assembled on May 10th at the Ministère des Affaires Etrangères, where its sittings were continued until the signature of the Convention. It was opened by Mr. Durafour, the Minister of Health; Mr. Camille Barrère, the senior delegate of France, who had presided over the 1903 and 1911 conferences, was elected president, and Dr. H. Pottevin, who has since been elected director of the Office International, was appointed rapporteur-général.

Although the draft revision had been accepted as a basis by the representatives of the various Powers, several questions and even principles of action remained at issue, and involved long and close debate; but in the end a text was agreed upon and the Convention was signed by most of the delegates on June 21st. It should prove a good practical instrument, with enough elasticity to allow for the differing conditions of the territories concerned, yet sufficiently binding, on the one hand to ensure adequate defence against epidemics, and, on the other, to prevent exaggerated action.

The New Convention.

The scope of the Convention is extended to include typhus and small-pox in addition to plague, cholera, and yellow fever, which were dealt with in the last Convention.

It early became apparent that there were two tendencies of thought as to the nature of the Convention to be drawn up. One aimed at an instrument that should definitely regulate quarantine action under all circumstances and render its execution almost automatic. The other held that a Convention dealing with such varying conditions of climate and people must be an elastic instrument allowing individuality of action within clearly defined limits. The latter view was adopted by the conference, and this principle is clearly established in Article 15, which is in fact the key to the Convention's principle of action. It lays down:—

1. That any ship may be thoroughly examined by the sanitary authority on arrival if circumstances require it whether it is from an infected or from an uninfected port.
2. That the sanitary procedure is to be determined by the conditions existing on the ship and by the medical history of the voyage.
3. That it rests with the Government to determine in accordance with the Convention what procedure is applicable in its own ports.
4. That the measures laid down by the Convention are to be considered a maximum within which the Government may take action.

This elasticity of action is further assisted by Article 57, a very important Article which enables Governments, taking into account their particular situation, to make special arrangements among themselves so that the sanitary measures of the Convention may be more efficacious and less burdensome. Thus, for instance, States can mutually arrange to dispense with elaborate precautions at the port of arrival in consideration of special precautions taken at the point of departure or on the voyage.

Notification of Diseases to Foreign Governments.

Under previous Conventions notifications were made through diplomatic channels—a method which was slow and cumbersome. It was clear that the time had come to establish a central clearing-house of sanitary information, which should rapidly communicate to all concerned information of the occurrence or outbreak of epidemic diseases, and which should collect and distribute to the signatory States details of the sanitary condition, equipment, and organisation of the various ports. The Convention constitutes the Office International the authority responsible for carrying out these duties. At the same time it empowers the Office to make arrangements with the Health Committee of the League of Nations, the Pan-American Sanitary Bureau, and similar organisations, to facilitate the fulfilment of its duties under the Convention, on the understanding, however, that these arrangements do not involve any infringement of the Rome Accord. Thus to carry out its new duties the Office International will be able by arrangement to make use of the Epidemiological Intelligence Centres already existing—i.e., the League of Nations Bureau at Geneva and its branch office for the Far East at Singapore, and the Pan-American Centre at Washington and its branch at Montevideo.

Classification of Ships and Deratisation.

Under the old Convention the conditions which caused a ship to be classified as healthy, suspected, or infected were laid down in a common category for the three diseases, in spite of the epidemiological differences in their behaviour. In the new Convention a separate subsection is devoted to each of these diseases; these subsections specify for each disease the conditions which entail a ship's being classified as healthy, suspected, or infected, and state what action should be taken in each case. This rearrangement will be a great advantage to all concerned.

Certain alterations were necessitated by increased epidemiological knowledge. The paramount importance of the rat and the flea in the spread of plague had to be recognised. It was not considered advisable to make the first case of rat plague notifiable under Article 1 of the Convention in the same way as human plague, although this was strongly urged by some of the signatory Powers; but under Article 6 Governments undertake to do all in their power to keep themselves informed as to the conditions of rats in their ports, and to furnish full information on the subject at regular intervals to the Office International.

The Convention exacts either the permanent rat-proofing of ships or deratisation every six months. Ships thus treated must be given a certificate

exempting them from further deratisation for six months; but, on the other hand, the sanitary authority is given authority to deratise a healthy ship in exceptional circumstances and for well-founded reasons communicated in writing to the captain. In this way the balance is maintained between the desirability of keeping down the rat population on ships and the hardship inflicted on shipping interests by repeated and possibly unnecessary deratisation.

Regulation of Travel and Transit.

Cholera.—The Convention recognises the importance of anticholera vaccination by exempting in certain cases persons vaccinated against cholera from detention under observation. The importance of the cholera carrier receives limited recognition only. The conference adopted the view that the examination of healthy persons travelling on ships coming from an infected area demands such elaborate organisation and technique and involves so much inconvenience to passenger traffic that its enforcement is impracticable, and that reliance should rather be placed on anticholera vaccination. The Convention, however, requires persons under observation or surveillance to give facilities for bacteriological examinations if considered necessary; this enables healthy persons on an infected ship to be examined for the cholera vibrio during the period of observation or surveillance.

Yellow Fever.—The regulations dealing with this disease are remodelled so as to give full recognition to the part played by *Stegomyia calopus* in its transmission.

Emigrants.—A new section is introduced dealing with emigrants. This section enforces the medical examination of all pilgrims at the point of departure, so that rejections at the frontiers of countries of transit and destination may be reduced to the fewest possible, and recommends that certain medical and sanitary arrangements should be made at the port of departure and on the voyage.

Bills of Health.—A new Article recommends (1) that Bills of Health should be issued free of charge; (2) that charges for consular visas should be equivalent to the cost of service only; and (3) that special agreements should be made with a view to the gradual abolition of consular visas and Bills of Health. When the Office International is working as an intelligence bureau and port authorities are in consequence kept fully and promptly informed of the sanitary conditions at other ports, the need for Bills of Health and consular visas will have ceased to exist.

Merchandise and Baggage.—The new Convention lays down that merchandise and baggage arriving by sea and land may not be forbidden either entry or transit. The only measures permitted are disinsectisation, deratisation, and disinfection, and these only in special circumstances. This is a great advance on the 1912 Convention which permits the prohibition of entry of merchandise in the case of plague and cholera—a prohibition that cannot be justified on epidemiological grounds.

Pilgrimages.—The sanitary supervision of pilgrims travelling by the Hedjaz railway, entrusted by the 1912 Convention to the Constantinople Superior Board of Health, which ceased to exist soon after the outbreak of the world war, is now entrusted to the States traversed by the railway. Similarly, the sanitary supervision of the Black Sea ports and the Straits, formerly under the charge of the same Board, is undertaken by the Turkish Government which is a signatory of the Convention.

An important Article entrusts to the International Quarantine Board of Egypt the duty of transmitting to the sanitary authorities of the countries concerned and to the Office International all sanitary information as to the pilgrimage and as to the sanitary conditions of the countries through which the pilgrims pass. The International Quarantine Board, in addition to its other functions, thus becomes an intelligence bureau for the pilgrimage area.

MEDICINE AND THE LAW.

Milk Prosecution: Sample 50 per cent. Deficient in Fat.

THE Sale of Food and Drugs Acts are intended to protect the community from the disadvantages and dishonesties of adulteration. They penalise sales "to the prejudice of the purchaser" of articles of food or drugs which are "not of the nature, substance, and quality" demanded. Where the article of food is milk, cream, butter, or cheese, the Minister of Agriculture may make regulations determining what deficiency in the normal constituents of such foods, or what addition of extraneous matter or proportion of water, in any sample shall raise the presumption (until the contrary is proved) that the food is not genuine or is injurious to health. In 1901 it was provided by the Sale of Milk Regulations that, if a sample of milk (not being sold as skimmed, separated, or condensed milk) contained less than 3 per cent. of milk-fat, the milk should be presumed (until the contrary was proved) not to be genuine by reason of the abstraction therefrom of milk-fat or the addition thereto of water. In discussing lately the unsuccessful prosecution of a Norfolk farmer, it was shown that the standard of 3 per cent. of milk-fat can be easily evaded. The farmer, it may be remembered, showed that the deficiency of fat in a sample from his churns (a deficiency of 42 per cent. below the standard) was not due either to the abstraction of fat or to the addition of water. He and other witnesses proved that the milk had not been tampered with from the time it left the cow to the time it reached the purchaser. He had a perfectly good explanation of the deficiency—namely, that he had been adopting a course of partial milking, the fore part of two cows' milk being placed in churns for sale, the after part being left for the cows' calves. The prosecution alleged it was common knowledge that in such a course of milking the fore part of the milk is less rich in fat. It is common sense that, if a farmer knows that he is giving the calves the benefit as against the purchaser, his sale of the less rich milk (which thereby falls below the prescribed standard of purity) should be treated as a sale to the prejudice of the purchaser. The purchaser should at least have a right to be told that he is not getting what he expects. This, however, is not the law. Owing to the wording of the Acts and Regulations it was possible for the courts to decide in 1917 (in the Case of Grigg *v.* Smith) that, where there is a course of exceptional milking, the farmer is at liberty to prove his milk "genuine" if he proves that it has not been tampered with. It is genuine, of course, in the sense that it is natural milk, taken from the cow, unadulterated and undiluted, but the purchasers, who suppose that they are buying milk of the standard prescribed by the Regulations, are certainly prejudiced. The farmer's defence is easy. Unless there has been deliberate adulteration or dilution, he can call witnesses to say the milk was never tampered with. He has only to explain to the magistrates that he had adopted a course of milking which prejudices the quality of milk sold to the purchaser, and he escapes any penalty for selling milk to the prejudice of the purchaser. In the recent Norfolk case the magistrates suggested to the farmer that, if the after part of a cows' milk was being left for her calf, the milk of that cow should not be placed on sale. In an earlier case it is believed that the bench suggested to another farmer who had employed this defence that he should consider the use of oilcake or other special food to improve the quality of the cow's milk so that the purchaser did not suffer. But these magisterial suggestions carry no compulsion, and meanwhile the deficient milk is presumably sold at full price and the purchaser is, in fact if not in law, prejudiced.

This point has been emphasised by repetition since yet another milk prosecution has recently failed on the same ground. The Ilfracombe Urban District

Council, on Sept. 20th, prosecuted a farmer who had supplied milk of which a sample showed 50 per cent. deficiency in milk-fat. The bench dismissed the case, though holding the deficiency established, because it was not proved that the milk had been tampered with. The analyst reported that the sample did not contain added water; the prosecution suggested that there had been an addition of scalded milk. This the farmer denied, though in cross-examination he admitted scalding his evening milk which he said he gave to his calves and pigs. The statement made on behalf of the defence, as summarised in the *North Devon Herald*, was that the farmer kept shorthorns and crossbreds which were not rich milkers. One cow had a calf running by her side; another had just had the calf taken from her. In such circumstances, it was frankly admitted, cows would hold their milk back and it was said to be well known that the fat was contained in the last of the milk. If farmers will agree in this admission they will appreciate the purchaser's point of view. Calves are entitled to their natural nourishment, but the law must somehow manage to prevent the nourishment of the calf interfering with that of invalids and children.

Chemist's Supposed Error: Doctor's Initials Illegible.

A year or so ago in an action for damages in the High Court there was a question of the proper proportion of a drug prescribed by a doctor, and its decision turned upon the correct deciphering of the figures in the prescription. This case, in which the plaintiff did not succeed, is indirectly recalled by a recent incident in which a Birmingham chemist is said to have sold in error pills containing one-fourth instead of one-fortieth of a grain of strychnine. The purchaser had presented a prescription dated 1921, but the doctor's initials could not be deciphered, and the chemist, on discovering his error, was unable to identify and warn the purchaser. The prescription bore the name of Mrs. Penn. In the hope of retrieving the pills and avoiding any unfortunate consequences of the error he believed himself to have committed, the chemist is understood to have sent telegrams to all persons named Penn in the Birmingham directory and to have invoked the aid of the police and the publicity of the press and of the British Broadcasting Company.

It was a case apparently of absence of mind, not of misunderstanding the specified proportions of drugs. The lay public, however, will doubtless connect the incident with its habitual pessimism as to the legibility and intelligibility of doctors' prescriptions. Custom has sanctioned the use of the doctor's initials just as, in the different field of marine insurance, custom has sanctioned the initialling of brokers' slips. Initials are accepted by the law courts as equivalent to full signature (if intended as such) in cases under the Wills Act or in the authentication of agreements within the Statute of Frauds. In connexion with the Dangerous Drugs Acts, where it may be important to identify the writer of a prescription, regulations have enacted that the prescription "must be in writing, must be dated and signed by the medical practitioner, registered dentist, or registered veterinary surgeon as the case may be, with his full name and address." Parliament has insisted upon clear handwriting in dealing with another vocation. The Pawnbrokers Act of 1872 obliges pledge-books and pawn-tickets to be written "in a fair and legible manner." There is probably no other example of an express statutory obligation of legibility, though there are plentiful occasions when the law requires written signatures to certificates, records, and other documents. A deliberately illegible signature might conceivably be held no signature at all.

THE LISTER CENTENARY.—The centenary of Lord Lister's birth falls on April 5th next year, and the Royal Faculty of Physicians and Surgeons of Glasgow, the Corporation of the City, the University, and other local public bodies are conferring as to the best method of celebrating the occasion.

THE HUMAN FACTOR IN INDUSTRY.

REPORT OF THE INDUSTRIAL FATIGUE RESEARCH BOARD.

REFERENCE was made in our issue of Sept. 18th to the contents of the latest report[1] of the Industrial Fatigue Research Board; some of the investigations into human activity brought together in the admirable analysis given of the Board's work since its inception call for more extended notice.

Hours of Labour.

The topical subject of hours of labour has received much attention; here is a matter of which Mr. W. L. Hichens rightly says[2] it is "to-day a subject of political controversy rather than of scientific inquiry; this is to be regretted. . . ." Many studies of output by the hour of each shift, by each shift of the day, and by each day of the week, have been made. Curves representing the results exhibit human activity as varying with the type of work performed; for physical work the curve rises as the muscles warm up, but falls as fatigue comes on; for monotonous work the curve gradually declines, to rise as the spell draws to an end. Maximum output, as exemplified by the curves for the best workers, is found associated with curves which rise steadily from hour to hour, from shift to shift, and from day to day. Output being the objective of industry, study of curves so that their shape may be improved by modifications in length of spells, and in number of hours worked, and by organised rest pauses, becomes a subject for scientific research. Thus inquiries in steel smelting, tin-plate mills, and glass-making, when contrasted with textile processes, show that increase in hourly output follows reduction in hours of work in proportion to the extent to which the process is manual rather than automatic. The optimum periods for work can clearly be determined by simpler and more accurate means than the hit-or-miss methods of present-day disputes.

Other Factors: Ventilation, Illumination.

Hours of work, however, can only refer to prevailing conditions of labour; if these latter are modified by introducing labour-saving devices, adequate ventilation or improved illumination, the problem alters. Here the subject of ventilation, including the temperature and humidity of the air, has been the subject of extended research following up the fundamental principles laid down by J. S. Haldane and L. Hill. Thereby the whole outlook on ventilation has been profoundly changed; the objective now is to produce the correct cooling power of the air, having regard to the work in progress, more for heavy work, less for sedentary work; no longer are chemical impurities and emanations called in to explain the ill-effects of stagnant air. Instances are quoted from a number of industries of output varying from 10 to 15 per cent. with variations in the cooling power of the air. Ventilation is for the most part under direct control; but the different standards found in such diverse places as laundries, potters' shops, shoe factories, and weaving sheds, indicate that this control is not well exerted. Moreover, ventilation should be at least as cooling for the head as for the feet; the reverse more usually prevails, but when correct adjustment is made comfort and output are increased. One of the most striking points throughout the investigations is that optimum conditions for output, whether by arrangement of hours or of environment, are found to coincide with a minimum of sickness and of accidents—in other words, the greater is the attention paid to the human factor in industry the

[2] The Physical and Mental Effects of Fatigue in Modern Industry. By W. L. Hichens, Brit. Med. Jour., Sept. 11th, 1926, p. 480.

greater is the return, expressed in output, obtained for wages paid. Once this rule is appreciated, any influence which lessens lost time may be accepted as benefiting output; any influence which results in greater output may be accepted as beneficial to health. Thus the influence of illumination upon output—an influence which, though under direct control, is terribly neglected—is great; its influence on accidents can be measured; its influence on health is less easy to determine, but may reasonably be accepted; over 20 per cent. diminution in efficiency in weaving was found in the darker hours of winter days, while the weekly hourly output rose steadily from December to March.

Vocational Adaptation.

Even more fascinating than the results to be obtained by correct planning of hours and by perfecting the environment of work are those associated with fitting workers to their work and teaching them how to perform it; for example, improved movements at sweet-dipping produced 88 per cent. more output with less exertion, and reduced the time taken to polish table-forks by 61 per cent. Generally inefficient workers use actually more energy in accomplishing less than do efficient ones; thus one good metal-polisher produced 3·80 articles per minute for a total effort of 39·2, as against another who produced 2·54 articles for an effort of 71·3. Another matter of interest emerges; improvements in methods, in environment, or in hours, always benefit the less efficient workers most—i.e., they help most those who need help most, rather than thrust farther ahead those who have already outstripped their fellows. Since the bulk of the industrial population consists of average or poor workers, the increase in output, in health, and in contentment, to be obtained from adopting the principles which are thus being brought to light is hard to overestimate. From the health point of view alone this second industrial revolution, which is foreshadowed and has indeed already commenced, holds out prospects of hygienic and economic returns far greater and more lasting than all other schemes for betterment of the public health; the movement is advancing on power derived from scientific research.

We recommend perusal of this report, which is liberally illustrated, to everyone interested in the laws of health and activity, and congratulate the Board on work done in a difficult field, and their secretary on this excellent presentation of the whole.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Sickness Insurance Clubs.

THE quarterly report of the Board of Health shows a steady diminution during the last six months in the number of persons insured against sickness in the compulsory Krankenkassa, or panel clubs. This is due partly to the emigration of labourers, but chiefly to the protracted and increasing unemployment of a large proportion of the working population. Every month the membership shows a fall of from 5000 to 7000, the largest reduction being noted amongst tailors and furriers, and the next amongst bootmakers and joiners. On the other hand, there has been an increase in membership of the compulsory Krankenkassa of the federal civil service and the municipal service, though this is more than outnumbered by the decrease in the other clubs. As regards the medical service in these organisations, there are two systems in operation. The institutes of the civil and municipal and railway servants are allowed to choose any doctor they like so long as he lives in the same district, whilst other institutes appoint their own doctors at a fixed monthly salary. Both doctors and patients prefer the free choice system, for it allows the patient to consult a doctor in whom he has faith and confidence, and it enables the medical man to make a better living, since he is paid according to the amount of work he does.

Difficulties of Vienna Medical Organisation.

Economic conditions in Vienna have taken a decidedly bad turn during the last few years, and the change has especially affected brain-workers. Members of the medical profession have suffered perhaps more than any, and it was in the attempt to improve their position that a body called the Economic Organisation of the Vienna Profession came into being a few years ago. This has managed to bring some kind of order into the relations between doctors and their patients, both private and club, but the general trend of evolution in this country is directed towards socialisation, and increasing numbers of the population are coming under the scope of some or other Krankenkassa. The Economic Organisation has of course been unable to prevent this—a fact which has caused a good deal of dissatisfaction amongst practitioners. When a few months ago the new board of the Organisation was elected the opposition against its recognised head, Dr. Stritzko, was remarkably successful, and recently he has found it necessary to resign his position as the profession has received a further serious blow which he was unable to avert. Two new gynæcological and obstetric hospitals with 240 beds have been opened in Vienna, where private patients, relations of members of the Krankenkassa, will be received for confinement—an arrangement which deprives the general practitioner of prospective patients. The resignation of Dr. Stritzko leaves the Organisation without a leader, and it is possible that it will fall to pieces and that the profession will thus lose a valuable means of defence. Every effort is, of course, being made to prevent such a lamentable event.

The Accident Hospital of Vienna.

A year or two ago the Union of Sickness Insurance Institutes of Austria, after a thorough study of the statistics of industrial accidents, founded a special hospital for accident cases amongst its members. In the report published by the union it was shown clearly that in the vast majority of such cases the actual losses of the institutes and their insured members——due to cost of treatment and loss of wages and time—could be reduced by 90 per cent. if immediate and adequate aid was provided to the victims of the accident. In the hospital, which is an absolutely independent corporation, all cases of industrial accidents, as well as all other accidents, are received, and a specially trained staff is entrusted with investigation into every single case, so as to get a clear insight into its technical and objective features. An operating theatre fitted with all appliances for orthopædic surgery, a hall for mechanotherapy and electrotherapy, and, of course, a first-class X ray outfit are to be found at the hospital, which is in the centre of the industrial district of the capital. Forty beds are provided for, but at present only half of this number are in use as the majority of the patients are out-patients. The staff consists of the chief surgeon, two assistants, one X ray specialist, two visiting physicians, and six nurses. The first report shows that this accident hospital has saved the insurance institutes about £18,000 in the first year.

Blood Comparison in Forensic Medicine.

In a paper presented to the Medico-legal Institute of Vienna recently Prof. H. Sperl and Prof. Werkgartner discussed the attitude of the law towards the newer methods of forensic medicine as practised in this country. Only reluctantly, as they pointed out, is any use made of methods which are now available to settle some important questions of paternity. The discovery of the four human blood-groups is now recognised in the law courts as a legitimate proof—in the negative, of course—and it is interesting to note that in all Austrian hospitals the history of the patient must henceforward contain a note of his blood-group. Recently quite a number of paternity suits have been

heard in which claims have been substantiated by this method and previous judgments have had to be reversed. Three times men who had been paying for the support of their alleged offspring for various periods have had their cases reopened and made good their denial of paternity, with the result that they had no more to pay for upkeep. It may also be remarked that personal identity can be established or strengthened by the examination of the blood-group, when dactyloscopy, for instance, is impossible. But a wider scope is open for the blood-test in the diagnosis of blood-stains. When such stains are found on clothing or on the body of a person in connexion with a suspected crime they are mostly attributed by the accused to epistaxis, or menstruation, or to some slight injury, or to domestic animals. The determination of the blood-group of the suspected individual will very often settle the question at once, but the forensic doctor must bear in mind that damage by external factors is sometimes very detrimental to the normal reaction of this test, which should therefore be left to experts.

Municipal Sanatorium for Tuberculosis.

Three years ago the City of Vienna opened a special sanatorium for tuberculosis, consisting of 18 pavilions, situated in a huge park, facing south, on the outskirts of the city. Up-to-date equipment, including laboratories, surgical and X ray apparatus, and facilities for recreation ensures the highest degree of efficiency in treatment. Women and children of 4–14 years are the only patients, and 500 of them can be accommodated; they remain for periods of not less than three and not more than six months. Two pavilions, for 40 patients each, contain mild cases of active tuberculosis without bacilli in the sputum; in another group of pavilions are housed 100 children with affected hilus glands and slight pulmonary disease; whilst a third group contains 80 beds for open and closed disease of mild and moderate severity, and 60 beds are devoted to cases with open cavernous disease and laryngeal tuberculosis. The chief agents in treatment are the open air, hydrotherapy, and natural or artificial sunlight; the normal diet contains 3000 calories, increased as required, and two pints of pure milk daily is the minimum dose for each patient. Pneumothorax and tuberculin treatment are, of course, used where indicated, also the laryngeal phototherapy of Wessely. The sputum is disinfected in a special department and so are the books read by the patients. The children are kept constantly in the open air and are taught by special school-teachers. Instruction in prophylaxis and hygiene is given to every inmate of the institute, which has had 3523 patients since May, 1923.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics for 1925 for three countries.

Name of county.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.	
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Infant mortality.	Maternal mort. from childbirth.
Derbyshire ..	611,700	20·4	11·4	0·79	0·99	2·3	1·4	78	3·8
Hampshire ..	405,800	17·8	11·1	0·77	1·40	1·5	1·8	52	4·3
East Sussex ..	260,100	13·6	12·0	0·79	1·72	1·7	2·1	44	2·7

Derbyshire.

Dr. W. M. Ash points out that the south-western and western portion of the county is undulating agricultural land, whilst the northern part is mountainous, and the eastern part is a coal-mining and industrial area. A great deal is being done to meet the shortage of houses, but much more is required. During 1925, 582 houses were erected under housing schemes and 1707 by private enterprise with State assistance. Groups of houses, built adjoining existing villages and sometimes doubling the population of these, create drainage difficulties. The sewage arrangements cannot bear the additional burden, and owing to the low rateable area before the new houses are erected the extension of the sewerage scheme cannot be undertaken. On the other hand, it is a costly matter to provide temporary cesspools which will be abolished when the sewage works are ultimately extended.

The county council has provided maternity homes at Ashbourne and Ripley, and has contracted with the Chesterfield Corporation for the use of four beds at the Chesterfield maternity home. During the last financial year 67 cases were admitted to the Ashbourne home at a net cost to the county of £335, whilst 124 cases were admitted to the Ripley home at a cost of £429. At the request of the Ministry of Agriculture samples of water from the rivers Trent, Derwent, and Erewash were taken for analysis on July 16th. The samples of the two former were satisfactory as regards dissolved oxygen, except the Derwent sample taken at Borrowash Bridge. The samples of the Erewash, on the other hand, came out badly. The Erewash is a small stream with numerous factories and sewage works in its winding course, and its gradient is slight. In these circumstances the stream becomes a series of sedimentation tanks washed out with each flush of storm water. There is no sign of fish life until near its junction with the Trent.

As Derbyshire is a large milk-producing county clean milk competitions are promoted wherever possible. A prize fund is organised, with subscriptions from various public bodies, private individuals, and big milk buyers. Surprise samples are taken of each competitor's milk and tested for dirt, for the presence of *B. coli*, and for rapidity of souring. Up to the present the large number of competitors has prevented bacteriological counts, tubercle inoculation tests, and examinations of the cows and cow-sheds, but it is hoped shortly to include all these procedures. At the show in connexion with each contest an exhibit shows the results of the tests; the creditable exhibits are labelled with the names of the competitors, the discreditable bear numbers only. After the Tuberculosis Order came into force on Sept. 1st, 1925, energetic action was taken to weed out advanced tuberculosis from the herds. Thus during the last four months of the year 553 cows were slaughtered, of which 454 had advanced tuberculosis and 91 had tuberculosis not so advanced. Dr. Ash emphasises the importance of having the cow-sheds disinfected after the removal of the tuberculous cows, and the farmers are recommended to adopt a system of disinfection similar to that advocated by Dr. W. G. Savage, of Somerset. The samples of milk taken under the Tuberculosis Order are tested by direct microscopic examination and by animal inoculation if the former is negative. Of 66 samples so examined 6 were found positive by direct examination and 5 by the inoculation test. In the ordinary examination of mixed milk samples for tubercle bacilli 28 out of 300 samples gave a positive result (9·3 per cent.).

The death-rate from cancer has been almost stationary in the county during the past ten years. Dr. Ash thinks that everyone knows the need for early operation, and that the reason why cases do not come to the surgeon early is because the condition is frequently symptomless. Propaganda has taught everyone that a lump in the breast may be cancer, but has not dispelled the fear of the knife,

and Dr. Ash cannot see how that is going to be done by lectures or pamphlets. The patient's own doctor is the right person to do it. At the same time maternity and child welfare centres are suitable places from which to spread knowledge of the seriousness of bleeding about the time of the menopause.

The number of known cases of encephalitis lethargica was 43, as compared with 84 in the previous year. Dr. Ash hopes that the provinces will follow the example of the Metropolitan Asylums Board, which has provided accommodation for 100 London children suffering from the after-effects of this disease. He is sanguine about the prospects of immunisation against scarlet fever, diphtheria, and measles.

Bretby Hall Orthopædic Hospital has just been completed for the reception of 50 cases of tuberculosis of bones and joints in children, and Dr. Ash thinks it should also be used for the accommodation of children crippled by non-tuberculous causes. He considers that the attitude of the public towards cripples in the past has been one of apathy, and that few people have tried to understand their problem. The first point is that a very large proportion of the cases of severe crippling could have been ameliorated if not entirely cured. The second is that only about 10 per cent. of cripples need be excluded from an ordinary competitive life if they are properly looked after and properly trained. The cripple wants to be able to live as normal a life as possible. The herding of cripples is degrading to them and stimulates a variety of objectionable public sympathy. It is well to remember, says Dr. Ash, that a defect such as the loss of a leg or arm is no bar to such sports or games as golf, tennis, swimming, motoring, and cycling. The need for higher education for cripples is pressing. All brain work, clerical work, private secretaryships, and domestic service can be quite well performed by cripples. On a recent visit to two large well-known hospitals for cripples Dr. Ash found no cripples employed on the staff. If this is the attitude of such institutions the general public will hardly be likely to employ them, and they will be allowed "to drift into the soul-destroying employments that have alone been open to them in the past."

Hampshire.

Dr. Robert A. Lyster states that it is becoming increasingly obvious that the combination of official public health work with general practice is to the detriment of both. There are two ways, he says, in which a whole-time officer, free from practice, can be secured by any health authority. Either a number of small health authorities may join to form a combined district, or any health authority may adopt the scheme of the Hampshire County Council and appoint as its medical officer an experienced member of the county staff. Since this second scheme was instituted 5 out of the 22 rural districts and 1 of the 16 urban districts have adopted it.

The county council has made arrangements for the reception of maternity cases by six institutions situated in various parts of the county. The growth in the number of maternity and child welfare centres has been very rapid. At the end of 1916 there were five such centres. At the present time there are 80 in the administrative area, all run on voluntary lines. There are 550 voluntary workers associated with the scheme, and it is estimated that two-tenths of the time of the ten assistant county medical officers is taken up with this work. Dr. Lyster considers that, owing to the demand for more centres and the offers of further voluntary help, it would be justifiable to increase the county medical staff in order to allocate the equivalent of the services of four whole-time medical officers to this work. Arrangements have been made with eye hospitals or departments at Southampton, Salisbury, Bournemouth, and Portsmouth for the admission of mother and child in cases of ophthalmia neonatorum. In order to save delay Dr. Lyster thinks this disease should be notified direct to the county medical officer of health. It has been found that some midwives are reluctant to call in medical aid in these cases, and the Ministry has advised that local supervisory authorities might refrain from exercising their power of recovery of the fee in this class of case, so that nothing shall stand in the way of the midwife seeking prompt medical aid. The whole question of the recovery of fees from the relatives for medical help called in by the midwife has been considered by the county council, and as a result an insurance scheme has been adopted. Under this scheme the expectant mother who engages a midwife may pay 5*s.* to the county medical officer. In return for this payment the county council will pay the fees of the medical man who may need to be called to the assistance of the midwife.

In certain areas in the county the nurses of district nursing associations have acted as school nurses, tuberculosis nurses, and health visitors. This arrangement has been found to have serious disadvantages and is now only in operation in a few parishes. The supervision of the midwives in the county is carried out by the superintendent of the County Nurses Association under the direction of the county medical officer, and a payment is made by the county council for these services.

Dr. Lyster is of opinion that notifications of tuberculosis should be made direct to the county council, the authority responsible for treating the disease. The Ministry of Health suggested that with a view to closer coöperation boards of guardians should appoint the tuberculosis officers as consultants to their institutions. Ten boards of guardians in Hampshire expressed their willingness to coöperate in the way suggested, but 11 did not see the necessity for the proposal. A comparison of the quinquennium 1921–25 with 1909–13 shows a considerable fall in the tuberculosis death-rate. Thus in the rural districts the rate from pulmonary tuberculosis has fallen from 0·71 to 0·62 per 1000, and the rate from all tuberculosis from 0·92 to 0·79; whilst in the urban district the rate from pulmonary has fallen from 0·75 to 0·68, and the rate from all forms from 0·99 to 0·85. Dr. Lyster thinks that it would be a good thing if the mental deficiency work were centred in the medical officer's department, instead of being divided, as at present, between the offices of the clerk, the medical officer, and a voluntary society. He suggests that it would be easy for him to obtain the assistance of many voluntary workers as for maternity and child welfare work.

Dr. Lyster expresses very decided opinions in favour of sterilisation in dealing with mental deficiency and in favour of the use of prophylactic outfits for the prevention of venereal disease, issued with "clear and concise instructions."

East Sussex.

Dr. A. G. R. Foulerton reports that during 1925 185 houses were provided under housing schemes and 1297 by private enterprise, and that about 694 houses were in course of construction at the close of the year. During the last five years the number of fully trained midwives has increased from 134 to 140, while the number of "bona fide" midwives has fallen from 20 to 5. Midwives attended 1805 of the births, and sent for medical aid in 211 cases before the child was born, and in 191 other cases, either for the mother or baby, after the confinement. In 513 further cases the midwife was engaged as a maternity nurse, a medical practitioner being present at the confinement. The total births numbered 3526. Arrangements have been made for the admission of maternity cases to institutions at Brighton, Crowborough, and Tunbridge Wells. Of the 59 cases thus admitted 17 were cases of difficult labour, 25 were cases in which antenatal observation had detected abnormalities, and 17 were admitted on account of unfavourable home conditions. At the close of the year there were 31 maternity and child welfare centres. The scheme for the coördination of the

county council's health nursing work with that of the East Sussex Nursing Federation continues to work very well. In parishes where there is no district nurse the five district nursing superintendents of the Federation carry out the routine visiting of infants and children under 5 years of age. The district superintendents also supervise the infant visiting work of the district nurses, give talks on infant care, &c., at the centres, and supervise the work of the 186 midwives practising in the county area. They also pay special visits to cases of ophthalmia neonatorum and give assistance in the medical inspection of school-children and at the tuberculosis dispensaries. Sixteen cases of encephalitis lethargica were notified, and there were ten deaths from this cause. At the close of the year the council was looking after 187 mentally defective persons, 67 of these being maintained either in certified institutions or approved workhouses, 13 under guardianship, and 107 under supervision in their own homes. The county council subsidises the East Sussex Voluntary Association for the Blind. Altogether 300 blind persons have been registered, and good progress has been made in providing for the more pressing needs of the necessitous blind in the county. The County Education Committee has provided education in special schools for all blind persons under the age of 16 who need it, and has also provided secondary or technical education for blind persons over the age of 16 who are likely to benefit.

Two interesting charts show the decline in the infant mortality and in the death-rate from pulmonary tuberculosis during recent years. Thus the infant mortality chart shows a steady decline from 100 at the beginning of the century to the present rate of 44, while the pulmonary tuberculosis rate shows a decline from 0·8 in 1909, interrupted by an increase during the war years, to the present figure of 0·6.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 25TH, 1926.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 121 (last week 120); scarlet fever, 1628; diphtheria, 1023; enteric fever, 103; pneumonia, 471; puerperal fever, 49; cerebro-spinal fever, 3; acute poliomyelitis, 41; acute polio-encephalitis, 3; encephalitis lethargica, 36; trench fever, 1; dysentery, 21; ophthalmia neonatorum, 115. There were no cases of cholera, plague, or typhus fever notified during the week. The reported cases of poliomyelitis have notably abated. The large majority of small-pox notifications come as before from the county of Durham.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox, 3 (0) from enteric fever, 1 (0) from measles, 3 (1) from scarlet fever, 27 (5) from whooping-cough, 29 (7) from diphtheria, 239 (58) from diarrhœa and enteritis under 2 years, and 23 (7) from influenza. The figures in parentheses are those for London itself. Since the issue of this return a death from small-pox has been returned from Willesden. A woman of 43 was infected from her husband lately returned from Paris, and died in the small-pox hospital at Kingsbury of a virulent form of the disease.

NEW SWANSEA HOSPITALS.—The foundation-stone was laid at Swansea last week of a new isolation hospital which will accommodate 118 patients and an administrative staff of about 40, at a cost of £80,000. On the same day took place the opening ceremony of a new maternity hospital containing two wards of five beds each and an isolation ward.

MANOR HOUSE ORTHOPÆDIC HOSPITAL. — This hospital at Golders Green has been presented with a sunray lamp department and a motor ambulance by the London General Omnibus Company's Employees' Friendly Society. The hospital, which is under the control of the Industrial Orthopædic Society, is stated to be the only institution of this kind managed and supported entirely by working men.

Correspondence.

"Audi alteram partem."

REFORM IN MIDWIFERY

To the Editor of THE LANCET.

SIR,—I unite with Prof. Theobald in the hope that midwifery practice in this country should be an example to the world. When he states that our official statistics are dreadful, every conscientious obstetrician will agree with him, but can he show me a country where they are as good? The Rotunda Hospital occupies a very small part of Ireland. The population of London alone is greater than the whole of Ireland. Are the catastrophes in Ireland less numerous than they are in London?

Prof. Theobald makes the startling statement: "There is one solution to the problem which *has not been given a fair trial* and that is an *improvement in the teaching of midwifery.*" (The italics are mine.) Had he been interested in obstetrics as long as I have, he would know that the teaching of our subject has improved out of all recognition during the past 20 years. He suggests that we should have several hospitals of the improved Rotunda type. They would need to be much improved to better the hospital conditions we already have. Every important city in England has its Rotunda. London is simply teeming with its Rotundas, of greater or smaller size. Each has its teachers who cannot be surpassed either as teachers or as clinicians. Herein the student is taught the importance of Epsom salts as a preventive of eclampsia. He is taught ad nauseam that 95 per cent. of women can and do deliver themselves. He learns that forceps extraction is a rarer operation than is appendicectomy in a surgical unit; and, above all, he is taught that in a lying-in clinic not more often than some half-dozen times in the year is it necessary to apply the forceps until the fœtal head can actually be seen at the vaginal orifice. These lessons the student takes with him into his practice; he never forgets them; but for reasons I shall mention later he is unable always to carry them out.

Let me touch as briefly as I can upon the practice of midwifery as the student sees it in hospital to-day. In the first place, he sees antenatal care—the very key to obstetrics. Here I join issue with Prof. Theobald when he says: "The antenatal clinics, with all their potentialities for good, may, in fact, be a source of danger, for they have made possible an enormous amount of meddlesome operative midwifery." Is he adverse to version in breech presentations? Does he deprecate our habit of examining a woman under an anæsthetic when we have the slightest doubt as to whether slight disproportion be present or not? Is he in favour of the scandalous practice of allowing a woman to have a trial labour and, this failing, to perform Cæsarean section? My point is that we should *know for certain* long before a woman goes into labour whether her baby will pass naturally through her pelvis or not. This knowledge can only be gained in the antenatal clinic, and when the student has grasped its importance, he has learnt volumes of midwifery. I should refer to this practice as precautionary rather than meddlesome.

Prof. Theobald is evidently a strong advocate of rectal examinations during labour. I had hoped that this ghost had been laid long ago. But even a student might well ask, if it is dangerous and unnecessary to examine per vaginam, where is the need to attack the rectum? Vaginal examinations should always be made twice during labour. First, when the membranes rupture to make sure that the cord has not prolapsed—a very important point, for I have seen this accident in several primiparous women with the head deep in the pelvis. And again, when the second stage has exceeded two hours in order to exclude persistent occipito-posterior presentation.

We cannot determine per abdomen if the occiput has rotated backwards. Per rectum we are able to feel sutures and fontanelles; but to rely on sutures and fontanelles to determine the exact position of the head is simply asking for trouble. We can be certain of a persistent occipito-posterior presentation only in one way, and that is by locating the ear. I have never been able to locate an ear per rectum.

I am not surprised that Prof. Theobald has discarded his Garden-of-Eden method of delivery, for its results are horrible. I have little greater praise for his modified Garden-of-Eden method with its 21 per cent. of perineal tears in primiparous women. Let me beg Prof. Theobald to try once more with properly directed support to the perineum. If he is then still dissatisfied, let him take a series of 100 primiparæ, and let him in each lift the head off the perineum with forceps under deep anæsthesia. His diminished percentage of tears will amaze him, and his morbidity will not be perceptibly increased; whilst at the same time he will be taking a golden opportunity of demonstrating to students what an essentially delicate operation a forceps extraction should be.

Finally, the tone of his communication leads me to suppose that he has had little, if any, experience of private practice, either specialist or general. Without it he cannot hope to trace the source of our trouble to rock bottom. With such experience we can well cease to wonder why so many catastrophes are admitted to hospital, and begin wondering why such catastrophes are not more numerous. The private doctor is driven from pillar to post by the patient's relatives. He receives an urgent summons, and on arrival he finds that the patient has been in labour for barely half an hour. On the staircase he trips over the husband who is seated there with his head between his knees, groaning and unshaven. In the bedroom he will be confronted by the mother-in-law who wants to know when something will be done. There, too, he will meet the woman from next door who is pouring scent on the victim's forehead and saturating the room with noxious vapours. He finally runs up against the patient's own mother who has come up from the country especially for the confinement, and who, having had children herself, of course "understands things." Under such circumstances is it to be wondered at that sometimes we do things contrary to our better judgment and contrary to what we teach and have been taught? No, Sir, the fault does not lie in our teaching. It is not altogether to be found in our hospital system, inadequate as this may be for our needs. The *fault is to be found in the patient's home*, and it matters not whether that home be rich or poor, in this country or in any other. I personally see no reason to hope for any marked improvement in our statistics until we have legislation rendering it illegal for a woman to be confined in the bosom of her family.

I am, Sir, yours faithfully,

ANDREW MCALLISTER.

Wimpole-street, W., Sept. 30th, 1926.

To the Editor of THE LANCET.

SIR,—Whilst appreciating the basic truth of Prof. Theobald's argument, that the results of midwifery in this country are bad, I think there is a possible danger in the general application of his conclusion that we must go back to the "Garden of Eden" method of delivery. It is true, Prof. Theobald states, that the solution of the problem "lies in a return to Nature and to better midwifery"; but the underlying notion is that a "return to Nature" should be the main factor. But Nature is a fickle mistress; she acts blindly, irrespective of consequences. From her point of view, if an individual dies or becomes pathologic, it does not matter; if a race is wiped out, she is unconcerned.

In innumerable diseases, Nature if left to herself leads to annihilation of the individual; Art comes in, and by opposing Nature, frequently prevents such disaster. I instance simply appendicitis; what can be more natural than this disease? It is true that if left to himself, the patient frequently recovers, but even in that case is not always continuously happy. In many other cases, non-interference results in speedy death of the patient. Can, then, we trust Nature in appendicitis, in pneumonia, in typhoid fever? Can the wet packs, the cooling of the body, by artful man—opposing Nature—be disregarded? Are, then, these diseases not natural? How, then, in pregnancy and parturition can the individual be left without concern to Nature?

Prof. Theobald, apart from the immediate deaths, assigns to bad midwifery two results: one is the result of sepsis, the other of trauma. He minimises the possibility of endogenous infection. He has tried in vain "to discover an authentic case of fatal sepsis that occurred in a woman who had never been vaginally examined." "The vast majority of morbid cases are made morbid by infection introduced from without." That may be true, but instances are not rare of some infection occurring without any vaginal examination. A patient of my own, unexamined by myself or by the attending nurse, developed on the tenth day a white leg. The child was born before my arrival, and the nurse I could trust. But plegmasia alba dolens, presumably, is due to infection. Prof. Theobald lays no stress on the effect of coitus late in pregnancy, supposed by some to assist delivery. Nor does he refer to the genesis of a subsequent prolapse after precipitate labour. The disabilities ensuing on parturition are not all due to sepsis, there is frequently left a weakness of the abdominal wall or a laceration of the pelvic floor musculature. To these he does not specifically refer, but the patients so affected form perhaps the greatest number of the patients attending the gynæcological out-patient departments of our hospitals.

Reform in midwifery certainly is necessary, but improvement will not occur by leaving the parturient woman to Nature. Reform will only ensue with the rise of a "better midwifery"; and a better midwifery will only result when a fuller, a more complete understanding of the "normal" becomes known. I am, Sir, yours faithfully,

Rugby, Oct. 1st, 1926. R. H. PARAMORE.

POST-OPERATIVE TETANUS.

To the Editor of THE LANCET.

SIR,—After reading Dr. Dyke's article in the issue of Sept. 18th on post-operative tetanus with identification of the organism, I think it may be of interest to mention a somewhat similar case which occurred at the Royal Free Hospital this year.

The patient was a married woman aged 40, on whom a straightforward myomectomy was performed on March 30th. She had a normal convalescence until April 12th, when she complained of slight stiffness in the jaw on the right side. She had a carious tooth on that side and the symptoms were thought to be due to it until next day when the jaw became more stiff and later in the evening a definite spasmodic attack occurred. She then showed a risus sardonicus but rigidity of muscles was confined to those of the head and neck only. She was immediately given intravenous and intrathecal antitetanic serum and sedatives, but became comatose and died early in the morning of April 14th. On post-mortem examination offensive puriform fluid was found in the uterine wound from which the bacillus of tetanus was isolated. There were also present necroses in the liver and an acute tubular nephritis.

The case is interesting because, as with the patient mentioned by Dr. Dyke, there were so few symptoms—in fact only one spasmodic attack, and the patient died shortly after their onset. I am indebted to Prof. L. McIlroy and Prof. J. H. Dible for permission to write about this case.

I am, Sir, yours faithfully,

M. SALMOND,

Gynæcological Registrar, Royal Free Hospital.

Sept. 29th, 1926.

THE PASTEURISATION OF MILK.

To the Editor of THE LANCET.

SIR,—I am instructed to write to you on the following matter.

Dr. S. G. Moore, Medical Officer of Health, Huddersfield, in his letter on the pasteurisation of milk which appeared in your issue of Sept. 25th, referred to "Grade A Certified Milk."

As you know, the following grades of milk are sold under licence :—

Certified Milk.
Grade A (Tuberculin-tested) Milk.
Grade A Milk.
Grade A Pasteurised Milk.
Pasteurised Milk.

Certified Milk is the highest grade of raw milk while Grade A Milk is the lowest grade of raw milk recognised by the Ministry of Health.

Misquotations of this kind are very confusing to the public and a great drawback to the movement generally.

I am, Sir, yours faithfully,

H. E. MILES,
Secretary, The Certified Milk Producers' Association.

London, Sept. 30th, 1926.

SCOTLAND AND VENEREAL DISEASE.

To the Editor of THE LANCET.

SIR,—The excerpt on Syphilis and Gonorrhœa and Associated Diseases with special reference to their Nature and Treatment and the measures adopted in Scotland for their Prevention and Cure (recently reprinted from the 1925 Report of the Scottish Board of Health by H.M. Stationery Office), which was the subject of an article appearing in your issue of Sept. 25th under the heading A Pamphlet on Venereal Diseases, shows an astonishing omission in that prophylaxis is not even mentioned.

This is an interesting and remarkable publication and indicates a temporary local success for the "conspiracy of silence" in regard to the prevention of venereal disease by personal disinfection. Prophylaxis is not even mentioned in relation to syphilis, and as regards gonorrhœa paragraph 27 does not contain the word disinfection but is headed Prophylactic and Abortive Treatment of Gonorrhœa, and commences:—

"The efficacy of the prophylactic treatment of gonorrhœa is scarcely in question provided that the appropriate measures are taken within a short period of exposure to infection with reasonable care and with ordinary intelligence, but (outside the Services) such measures by almost universal consent are regarded as the concern of the individual rather than of the community."

Now Sir Leslie Mackenzie is the leading (and in 1923 was the only) medical member of the Scottish Board of Health, and in view of his published opinions in favour of education in the prevention of venereal disease by personal disinfection the omission of any reference to disinfection is astonishing. In 1922 two papers by Sir Leslie Mackenzie were published by the Scottish Committee of the National Council for Combating Venereal Disease, the first paper containing the following paragraph :—

"It is absurd to say that there is any danger in teaching every person capable of being taught that the venereal diseases are each of them due to a definitely known germ and that as long as the germ lies on the surface it can be destroyed with a mild disinfectant. . . . In teaching these facts we are teaching things so simple that any person can understand enough of them to realise the danger of spreading the diseases, *the easiness of the methods of preventing them*, and the difficulty of curing them once they are acquired."

The Scottish Board of Health was represented amongst the witnesses before the Committee of Inquiry on Venereal Disease, presided over by Lord Trevethin, by Sir Leslie Mackenzie and Dr. T. F. Dewar. Sir Leslie Mackenzie in paragraph 4 of his written evidence stated : "I put special stress on the measures for prevention," and in paragraph 13 said :—

"All instructions as to methods of ablution and self-disinfection should be regarded as an integral part of a course of genital cleanliness generally."

In his cross-examination on this written evidence Sir Leslie Mackenzie, in reply to Question 131, said :—

"My view would be that the balance of opinion would be rather in favour of direct preventive treatment. I look upon this mere matter of immediate self-disinfection as simply part and parcel of the teaching that would cover the method of destroying germs on the surface of the body. Probably the answer in the biggest industrial centres would be favourable to the methods. My opinion is that if it is a sound thing to do, then on general lines we begin to argue about it and the argument might go on for years, but ultimately the committees would adopt that line."

Colonel Fremantle, M.P., then asked (Q. 133): "If the power were given to chemists to put these prophylactics on sale you do not see any difficulty in the Scottish Board of Health issuing or approving instructions to be given away with them?" To which Sir Leslie Mackenzie replied: "No, I do not in the least, but, of course, there I am speaking for myself. I am a member of the Board and that is the view I should express. I am the only medical member of the Board as it happens."

Dr. Dewar, in para. 12 of his written evidence, says: "Disinfectants such as are supplied to soldiers in barracks in Scotland might surely be sold or distributed along with appropriate instructions to the general public. Labels on the bottle and tube and accompanying instructions would make clear the method of use of the disinfectants. The instructions might be such as had received the prior approval of the central or local authority."

In cross-examination Dr. Menzies put the following question : "The objection (to disinfection depôts) is based on moral and not scientific grounds?" to which Dr. Dewar replied : "Yes, that is so," after which Lord Trevethin asked (Q. 33): "They allow their views on morality to overwhelm their views on humanity towards the individual sufferer from a disease which may cause his physical ruin?" to which Dr. Dewar replied : "I think it is because of the failure to appreciate the gravity of the disease. My experience is that since the real facts of the disease (a good picture of the disease in all its evils) have been presented to the population of Scotland they have expressed more or less their willingness to have it scientifically dealt with."

It would appear, therefore, that this latest official publication on venereal disease cannot be taken as representing expert medical opinion on the Scottish Board of Health or the opinion of informed members of the laity in Scotland.

I am, Sir, yours faithfully,

H. WANSEY BAYLY,
Hon. Secretary, Society for the Prevention of Venereal Disease.

Sept. 29th, 1926.

*** In this criticism of the reprint issued by the Scottish Board of Health on Venereal Diseases under Treatment, it is right to direct attention to the sentences dealing with "prophylactic treatment" of gonorrhœa and collating these with the personal opinions of the medical member of the Board and one of their medical officers. But the inference from those sentences is that the Board, if they have considered the matter at all, have not made any public announcement about it and hold that the present position is adequately indicated by the words "such measures by almost universal consent are regarded as the concern of the individual rather than of the community." These are highly generalised words, but as we read the Board's regulations affecting venereal disease it is open to a local authority to submit any proposals for personal prophylaxis, and, if any such proposals had been made, the Board's reply would, no doubt, have been available in a public form. The Scottish branch of the National Council of Social Hygiene carry on propaganda with public funds on the same footing as the Central Council. Attention may be drawn to the fact that the paragraph quoted from deals with "the prophylactic and abortive *treatment* of gonorrhœa," and that, as stated in the opening paragraph of the pamphlet, "the following descriptive summary of methods employed represents the actual practice of the centres now established. It is intended to impress on the public

the enormous importance of early and sustained treatment of venereal disease." The exposition is designed to place before the general practitioner a connected view of the treatment available and to be of use to all concerned in education and propaganda. Such a document, which is expressly confined to the work of the administrative institutions, cannot be criticised because it does not enter into detail on a complicated and difficult question like personal prophylaxis.—ED.L.

HELIOTHERAPY IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—Dr. C. B. Heald in his letter last week under the above heading asks whether, in the experience of your readers, the inverse square law is strictly applicable in the case of ultra-violet rays in clinical use. May I draw his attention to my experimental results in this connexion, reported in detail in THE LANCET of August 22nd, 1925 (p. 369). When the source of ultra-violet rays was a mercury lamp the inverse square law did not apply, since it is not a point-source. Calculations based on this law are thus liable to give variable doses, and might account for anomalous results.—I am, Sir, yours faithfully,

P. R. PEACOCK.

Cancer Research Laboratories, Middlesex Hosp., W., Oct. 3rd.

SANATORIUM TREATMENT OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—The fact that the presence or absence of tubercle bacilli has not been taken into consideration by Messrs Stocks and Karn in the grouping of the cases robs this investigation of a great deal of its value. Indeed, it introduces a very serious fallacy. Again, as Dr. Walters has pointed out, sanatorium treatment, to be of any permanent value, must be of long duration, certainly at least 12 months. To regard as "sanatorium treated" patients who have been in an institution for 15 days only seems absurd. The cases should be classified as "otherwise treated."

But one must admit that sanatorium treatment, especially if it is of short duration, has little or no effect on the ultimate progress of the cases discharged as improved or quiescent only. In them the mental factor comes into play; the patient loses heart, and with the first set-back he goes downhill rapidly. That is the reason why we prefer to cure one case rather than "patch up" 20, and when institutions are anxious to get "suitable cases" they have this in mind, and not mere statistical considerations as the authors suggest.—I am, Sir, yours faithfully,

Grampian Sanatorium, Kingussie, Oct. 4th. FELIX SAVY.

IS IT COVERING?

To the Editor of THE LANCET.

SIR,—Will you kindly give advice on a matter of medical ethics which may be of interest to others of your readers? A medical practitioner with a diploma entitling him to practise in the British colony in which it is granted, but which is not registrable in Great Britain, takes up a practice in a country where his diploma is registrable and where those on the British Medical Register also may practise. Is there any ethical or legal objection to a man with a registered diploma (in Great Britain) acting as assistant or as partner to the said practitioner? It is obviously needless for names of persons or places to be mentioned, so I sign myself LATITUDO.

*** The essence of covering, as defined in the Warning Notice of the G.M.C., consists in enabling an unqualified or unregistered person to engage in professional practice as if he were qualified or registered. The case related by our correspondent does not seem to come within this category, as both parties are legally entitled to practise under the medical laws of the country.—ED. L.

LONDON MEDICAL EXHIBITION

THIS exhibition opened at the Central Hall, Westminster, London, S.W., on Oct. 4th, and will close to-day (Friday), Oct. 8th, at 6.30 P.M. It is perhaps the largest of the series of exhibitions organised by British and Colonial druggists and the attendance has also been large. We give below a brief account of some of the more prominent stalls.

DRUGS AND PHARMACEUTICAL PREPARATIONS.

ALLEN AND HANBURYS, LTD. (37, Lombard-street, E.C., and 48, Wigmore-street, W.), showed a wide selection of pharmaceutical and dietetic preparations. Among new preparations was an "Acidophilus Culture" which is an improvement on the Acidophilus Jelly, being more stable, and Cellulose Flour for adding "bulk" material to diabetic preparations. Special attention was called to the Azoule Vacuum Extractors designed for taking samples of blood under conditions of sterility, and also to a stable form of sodium tetrabromphenolphthalein for X ray diagnosis of diseases of the gall-bladder. Prominence was also given to a toilet preparation, Odontase, a pleasant non-acid deodorant and germicidal dental cream, having for its basis magnesium hydroxide.—OPPENHEIMER, SON AND CO. (179, Queen Victoria-street, E.C.) exhibited in large variety their Bi-palatinoids and Palatinoids as well as Roboleine, a vitamin preparation, and a selection of various preparations for colloidal therapy.—BURROUGHS WELLCOME AND CO. (Snow Hill Buildings, E.C.). At this stall a wide range of products were exhibited. Grouped alongside photographs of the highly-magnified organisms responsible for certain diseases there were appropriate medicaments for dealing with the disorders, together with a selection of "Soloid" Microscopic Stains. A full range of "Tabloid" Animal Substances was shown, including "Tabloid" Thyroid Gland, "Tabloid" Mixed Glands, and "Tabloid" Parathyroid Gland. Attention was called to the Bismuth Salts of the firm, for which an exceptionally high standard of purity and physical and chemical uniformity is claimed. New drugs are "Avenyl" (a mercurial preparation soluble in hydnocarpus oil) and "Neostam." The former has been evolved for dealing with cases of syphilis complicated with leprosy. "Neostam" Stibamine Glucoside has been found of service in kala-azar, and in other conditions where tartar emetic has hitherto been used.—W. MARTINDALE (10, New Cavendish-street, W.). The following were prominently displayed: Methyl-Aspriodine, a new compound, containing the equivalent of 56·3 per cent. aspirin and 39·7 per cent. iodine, for inunction in rheumatic affections and as a local analgesic. "Auremetine," indicated in amœbic dysentery, being a combination of emetine, auramine, and iodine. "Mercurome," a valuable and potent antiseptic, of value in cystitis, pyelitis, and gonorrhœa. "Aspriodine," a compound combining the therapeutic properties of aspirin and iodine in stable combination, is said to be of value in rheumatic affections and arterio-sclerosis and wherever iodides have proved beneficial, being supplied in cachets or tablets. "Sedasprin" is the bromine analogue of aspriodine.

ENDOCRINES, LTD. (72, Wigmore-street, W.). At this stall there were exhibited a large number of glandular preparations, particular prominence being given to Anabolin and Hepatic Extract. The first-named is in tablet form for administration per os, and has been found active in some 70 per cent. of the cases in which it has been used. Hepatic Extract, which is available in ampoule form for intramuscular injection, is said to have a pr: found influence on blood pressure and it is stated that clinical experience has shown that in the average case of functional high blood pressure the intramuscular injection of 1 c.cm. of the extract results in a reduction of from 30 to 50 mm. during the first day.—G. W. CARNRICK

Co. (Brooks and Warburton, 40/42, Lexington-street, W.) showed wide selection of gland products, and ARMOUR AND CO., LTD. (Queen's House, Kingsway), in addition to a large number of glandular products, showed Digestive Ferments of all kinds, such as Pepsin, Pancreatin, Trypsin, and Surgical Catgut Ligatures, as well as such specialties as Glycerine Extract of Red Bone Marrow, and Elixir of Enzymes —Among the large display of pharmaceutical preparations shown by the ANGLO-FRENCH DRUG CO., LTD. (238A, Gray's Inn-road, W.C.). Adrepatine, a pluriglandular compound for the treatment of hæmorrhoids, and Homovir, a gland compound in tablets for the treatment of impotency and presenility, were particularly noticeable.—BRITISH ORGANOTHERAPY CO., LTD. (22, Golden-square, W.), exhibited a large selection of organotherapeutical products, including Lymphoid Compound and Serum, for functional nervous disorders and degenerative nervous and mental conditions, respectively; Ovamammoid Compound for menstrual disorders and the disturbances of the menopause; Pancreatokinase for diabetes mellitus and glycosuria, and Enterostasin for chronic constipation, auto-intoxication, and similar conditions.—NUJOL LABORATORIES (Albert-street, Camden Town). The products of this firm are Nujol, an intestinal lubricant, Cream of Nujol with agar, designed to overcome the objection of some palates to plain Nujol, and Mistol, which is a balanced combination of menthol, camphor, and eucalyptol with a pure mineral oil. This latter can be used in an atomiser, and has been successfully used in the treatment of nasal catarrh.—SCHERING, LTD. (3, Lloyd's-avenue, E.C.), showed a camphor extracted from turpentine which compares in every respect and particularly in price with the ordinary form of this substance. This firm also exhibited Veramon, sedative and analgesic, which relieves pain without inducing sleep. It is said to be free from toxic or habit-forming effects, and, in most cases, forms a harmless substitute for morphia.—DESHELL LABORATORIES (1–3, Brixton-road, S.W.) showed Petrolagar, a perfect emulsion of medicinal liquid paraffin and agar-agar.

Among the most striking exhibits was that of H. R. NAPP, LTD. (3 and 4, Clement's Inn, W.C.), where definite progress in therapeutic products was shown in several directions. In particular, Saprovitan A and B may be noticed, a vital bacterial protein for intravenous injection, and Obiturin for determining whether death has actually taken place. This production by a colour reaction distinguishes dead from living tissue. Another interesting exhibit by this firm was Normacol, a vegetable intestinal evacuant in granular form. A teaspoonful of this substance on passing into the bowel is said to swell to a bulk equalling the digested débris of 7 lb. of apples and 5 lb. of cauliflower, or 16 lb. of bread.—HOWARDS AND SONS (Ilford). The attractive display of this old-established house received much notice, among the articles particularly prominent being the Standard Æther, the Agotan brand of Phenylcinchoninic Acid, said to be indicated in rheumatism, gout, brachial neuritis, neuralgia, and an absolutely pure aspirin. Many fine chemicals were also shown, while attention was called to Howards' Hydrogen Peroxide, which is stable and has excellent keeping qualities.—GENATOSAN, LTD. (Loughborough, Leicestershire), while displaying their tonic food, Sanatogen and Genasprin, made a particular point of their vaccines for administration by the mouth.—HOFFMANN-LA ROCHE CHEMICAL WORKS, LTD. (7 and 8, Idol-lane, E.C.) showed a full range of various chemical preparations, including "Allonal," allyl-isopropyl-barbiturate of phenyl-dimethyl-dimethylamino-pyrazolon, a new synthetic, non-habit-forming hypnotic and analgesic, intended to relieve pain of all kinds and give sleep. "Omnopon" total opium alkaloids and "Omnopon" combinations. "Omnopon" (Roche) is a soluble opium derivative in which the whole of the opium alkaloids are presented in their naturally occurring proportions but in the form of soluble hydrochlorides. "Isacen," diacetyl-dihydroxyphenyl-isatine, is a tasteless, odourless, non-toxic laxative which is insoluble in water and dilute acids, acts only in an alkaline medium, is not absorbed, and has no action upon the kidneys. — CHAS. ZIMMERMANN AND CO. (9/10, St. Mary-at-Hill, E.C.). Besides calling special attention to Angiolymphe, a non-toxic vegetable composition indicated in tuberculosis as an intramuscular injection, made a special feature of the Dega brand of Lysol guaranteed to contain 50 per cent. cresols. While conforming to old standards in its qualities, this lysol has been considerably reduced in price. Other prominent exhibits of this firm were Idozan which presents iron in a readily assimilable form and does not cause constipation, Posterisan, a new vaccine therapy in the form of an ointment, and suppositories for the treatment of hæmorrhoids and allied conditions.—MENLEY AND JAMES, LTD. (Menley House, 64, Hatton Garden, E.C.), showed a therapeutically active iodine in an emollient base called Iodex, and made prominent Vitaminose, a chlorophyll vitamin compound intended to act as a food adjunct where the accessory food factor has been lost or impaired in preparation, culinary or mechanical.—C. J. HEWLETT AND SON, LTD. (35–42, Charlotte-street, and 83–85, Curtain-road, E.C.), included in their original preparations an antiseptic cream for eczema, abrasions and so forth, and a series of medicated skin lotions, Evapogens and Hormonigen, a combination of pluriglandular extracts for use in endocrine insufficiency.—MAY AND BAKER (Battersea, London, S.W.) called attention to Bistovol, bismuth acetylamino-oxyphenylarsonate, in ampoules of an oily suspension for intramuscular injection. This new preparation is for use in the treatment of syphilis. Sodium salt of N-phenylglycineamide-p-arsonic acid, Tryparsamide, for treatment of sleeping sickness (trypanosomiasis of man and mal de caderas of the horse) is claimed to have produced good results in general paralysis, tabes, and other forms of neurosyphilis. The sodium salt of theobromine-N-acetic acid—a new addition to diuretic medication—Mestarine, possessing marked advantages over theobromine and other derivatives of this compound by reason of its stability and ready solubility, was also exhibited by this firm.—SAVORY AND MOORE, LTD. (143, New Bond-street, W.), made a prominent exhibit of foods for infants and invalids and showed a wide selection of pharmaceutical preparations and drugs.—ANGIER CHEMICAL CO., LTD. (86, Clerkenwell-road, E.C.), exhibited their emulsion, petroleum with hypophosphites.—CROOKES LABORATORIES, BRITISH COLLOIDS, LTD. (22, Chenies-street, E.C.), showed a large selection of their original colloidal preparations and made a prominent feature of Collosol cod-liver oil. This takes the form of a 50 per cent. emulsion prepared with oil obtained from cod caught in home waters, the oil being extracted on board the fishing vessel, thus ensuring perfect freshness of the material. The preparation mixes with water, milk, or wine.—KAYLENE, LTD. (7, Mandeville-place, W.), showed various preparations of Kaylene (Colloidal Kaolin) for the treatment of chronic intestinal stasis, Colonol liquid paraffin possessing high viscosity at the temperature of the body, and a Swedish health bread, Spisbrod, which contains 100 per cent. of whole grain rye, while the DENVER CHEMICAL MANUFACTURING CO. (London, E.) exhibited their well-known antiseptic poultice, Antiphlogistine, which is indicated in deep-seated inflammatory and congestive conditions. —DIMOL LABORATORIES (40, Ludgate Hill, E.C.) demonstrated Dimol as a bactericide both in internal and external use. It is put up as a dentifrice, in the form of a syrup, pastilles, lavage powder, ointment, snuff, and dusting powder. Dimol as a bactericide is claimed to be 35 times more efficient than pure phenol.—BOOTS PURE DRUG COMPANY, LTD. (Nottingham), had a most attractive display of synthetic and medicinal chemicals, compressed tablets of drugs, solutions, surgical dressings, and sundries, and THE SEMPROLIN CO., LTD. (Carmex House, 18, Leather-lane, E.C.), displayed "Semprolin" Emulsion c.

Iodine (⅛ gr. in each fluid ounce), a preparation in which iodine is held in solution with even distribution. —PARKE, DAVIS AND CO. (50, Beak-street, W.) exhibited a new type of bacterial antigens, Immunogens, developed in the medical research laboratories of Parke, Davis and Co., and representing simple antigens almost free from toxin and bacterial cells. Attention was also drawn to Metagen and cod-liver oil emulsion—Metagen supplements the fat-soluble vitamin of cod-liver oil with the water-soluble vitamins of vegetable origin and provides a valuable remedy in cases of impaired nutrition.—NEWTON, CHAMBERS AND CO. (311, Gray's Inn-road) exhibited Izal disinfectant in various forms, and JEYES' SANITARY COMPOUNDS CO., LTD. (64, Cannon-street, E.C.), showed various preparations of Cyllin.

(To be continued.)

A FATAL CASE OF SMALL-POX IN WILLESDEN.

ON Sept. 29th Dr. G. F. Buchan (M.O.H., Willesden) was called in to see two cases (man and wife) by the medical practitioner in attendance. He found the man to be suffering from small-pox in a modified form and the woman to be suffering from hæmorrhagic small-pox. The cases were removed to the Willesden Small-pox Hospital the same day and the clinical features of these cases are described by Dr. A. G. Troup, medical superintendent, as follows :

Mr. M. F., aged 43 years. Vaccinated in infancy. Re-vaccinated in or about 1900.

Condition on admission to Hospital.—There were a few dry scabs on the hands, wrists, and feet, but the large majority of the lesions had completely healed, leaving no scar. It was not possible to differentiate accurately the site of all the pustules, but as far as could be ascertained these were as follows : three on face, a few on scalp, three on shoulders and neck, three on abdomen, two on flanks, four on arms, four on hands, one on right thigh, two on feet (dorsal surface).

The patient walked into the hospital and had nothing to complain of. On Oct. 2nd all scabs had completely disappeared, leaving a small scar in some instances.

Mrs. R. F., aged 44 years. Vaccinated in infancy.

Condition on admission to Hospital.—Temperature 97° F. ; pulse 64. A hæmorrhagic rash was present on the trunk, arms, forearms, thighs, and legs, being most marked in the axillæ, groins, and wrists. The hæmorrhages took the form of petechiæ and ecchymoses, the latter form being chiefly present in the axillæ and groins. A diffuse erythema was present on the trunk and extremities, most marked on the shoulders posteriorly. The face was slightly bloated and there were no hæmorrhages present in this region. The patient had a characteristic fœtor and was quite conscious. The conjunctivæ were injected only. The tongue thickly furred and the mouth dry. Metrorrhagia was present. There were excruciating pains in the back, and the patient was in great distress. There were no papules, vesicles, or pustules present.

A hypodermic of morphia was given and the patient remained quiet for about five hours. She was seen again at 11 P.M. The hæmorrhages on the trunk and extremities had increased in size and number. The face and lips were a livid hue and the former was more markedly bloated. The pulse could not be felt. The patient was very restless and in a semi-conscious condition and died at 11.45 P.M.

Inquiries into the history of these cases showed that Mr. and Mrs. F. had come to London from Paris on Sept. 5th and had gone to a West-central hotel, from which hotel they moved to a West-end hotel on Sept. 7th. On Sept. 8th Mr. F. became ill with pains in the back, headache, severe prostration, and a temperature of 105° F., followed two days later by a rash first appearing on the scalp and face and subsequently on the arms and legs as described above. On Sept. 19th Mr. and Mrs. F. moved to a nursing home in Brondesbury, Kilburn. On Sept. 24th Mrs. F. became ill with severe pains in the back, followed by headache, vomiting, extreme restlessness, and sleeplessness. On Sept. 26th an erythematous rash appeared in the axillæ and groins, subsequently becoming punctate, and on Sept. 29th it was as above described.

Mr. and Mrs. F. were in Paris during the last fortnight in August and apparently it was during the last week of that month that Mr. F. was infected. It is reported that there is small-pox in Paris. Mr. F. had been vaccinated and re-vaccinated and took the disease in a modified form. He apparently infected Mrs. F., who developed small-pox of the virulent type. Mrs. F. had not been vaccinated since infancy.

The medical officers of health of surrounding districts in which the patients had resided or from which the patients had been visited were communicated with. All contacts were traced as far as possible and vaccination advised and the necessary disinfection was carried out. At the West-end hotel the medical officer of health, Dr. Charles Porter, ascertained that one of the staff had been ill for about 36 hours with suspicious symptoms and that another of the staff was ill in Lambeth. Both of these cases have subsequently been notified as small-pox.

The usual period of two days which elapses between the onset of the disease and the appearance of the rash gives an opportunity for preventive measures to be taken, as it enables the patients (deemed non-infectious during this period) to be isolated. All medical practitioners in Willesden have been notified of the circumstances of the occurrence of the disease and are actively coöperating with Dr. Buchan to prevent, as far as may be, any spread. Should no further cases arise Willesden will be free of danger of spread from the patients imported into the district probably about Oct. 13th and certainly by Oct. 20th.

Medical News.

BIOCHEMICAL SOCIETY.—The next meeting of the society is being held in the Biochemical Laboratory, Cambridge, on Saturday, Oct. 9th, at 2.45 P.M.

HARVEIAN SOCIETY.—A clinical meeting of the Harveian Society of London will be held at St. Mary's Hospital, Praed-street, London, W., on Thursday, Oct. 14th. Cases at 8 P.M. ; chair to be taken at 8.30 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following demonstrations of specimens in the Museum will be given at 5 P.M. in the theatre of the College in Lincoln's Inn-fields. On Oct. 15th Sir Arthur Keith will show specimens of surgical and anatomical interest recently added to the Museum. On Oct. 22nd he will demonstrate the anatomy of the sacro-iliac region and its application to practice, and on Oct. 29th specimens illustrating disorders in the growth of bone. On Oct. 18th Mr. C. E. Shattock will demonstrate surgical conditions of lymphatic glands, and on Oct. 25th surgical conditions of blood-vessels, and on Nov. 1st scrotal tumours. The demonstrations are open to advanced students and medical practitioners.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Thursday, Oct. 14th, at 5 P.M., in the lecture room of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., Sir Thomas Horder will give the opening lecture of a series on Emergencies in Medicine and Surgery. On Friday, Oct. 15th, at 5 P.M., at the Royal Westminster Ophthalmic Hospital, Mr. M. L. Hine will give a lecture-demonstration on the Red Eye and the Significance of Circumcorneal Injection. Both lecture and demonstration are open to members of the medical profession without fee. An intensive three weeks' course in laryngology, rhinology, and otology is in progress at the Central London Throat, Nose and Ear Hospital. Beginning on Oct. 18th there will be a combined course in Diseases of Children in which the Paddington Green, the Victoria Hospital, and the Children's Clinic are participating ; this will include morning and afternoon sessions. On the same day a course in gynæcology starts at the Chelsea Hospital for Women, and an afternoon course in urology at St. Peter's Hospital, where there will be clinical work in the out-patient department, including cystoscopies, as well as daily lectures. A course of eight lecture-demonstrations is being given throughout the month at the London School of Tropical Medicine. Copies of all syllabuses, of the General Course programme, and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship, at 1, Wimpole-street, London, W. 1.

HOSPITAL DINNERS.—The annual Old Students' Dinner was held in the Great Hall of *St. Bartholomew's Hospital* on Oct. 1st, when Mr. W. 1. Holmes Spicer presided over a large gathering. In proposing "The Hospital and Medical College" Mr. Spicer reviewed the doings of a year, in which the most important occurrence was the completion of the Queen Mary block of buildings for the housing of the nursing staff. The next most urgent work in prospect was the provision of an operating theatre block in connexion with the new surgical building, in order to avoid the perilous journey across the square of patients from ward to operating room and back. The provision of a department for paying patients was under consideration, for, said Mr. Spicer, even the most wealthy will soon not be able to command the best treatment elsewhere. During the year 120 students had obtained qualification to practise and the same number had joined the Medical College. The severe loss of Prof. Lovatt Evans from the College was a gain to University College, where he now occupied the Jodrell Chair of Physiology. The midwifery department was shortly to have a whole-time resident assistant physician-accoucheur; this appointment and the research laboratory attached to the new department in memory of Dr. Herbert Williamson raised the hope of forming at some future time a professional unit in the University of London. The biggest scheme in prospect was the removal of the school buildings to the other side of Giltspur-street at an estimated cost of £140,000. Lord Stanmore, who responded, added that it was hoped next year to begin to build a residential college, without which no medical school could remain efficient and progressive. Sir Percival Hartley proposed "Our Guests" in a speech full of apposite allusions, response being made by Sir William Beveridge, Vice-Chancellor of London University, who warmly acknowledged the great part played by the medical schools in the life of London University, while contending that a university still had functions as such to perform. The evening terminated with a racy speech from Dr. Owen Lankester, who proposed "The Chairman."

The annual dinner of the *St. George's Hospital Medical School* was held at the Hyde Park Hotel, Knightsbridge, S.W., on Oct. 1st, when Captain the Right Hon. C. C. Craig, M.P., Parliamentary Secretary to the Ministry of Pensions, presided over a large gathering. The dinner was arranged at separate tables so that friends could be sure of proximity, and there were only two speeches on the programme, one from the Chairman, a member of the house committee of the hospital, and one from Dr. Anthony Feiling, the Dean of the school, in reply. Captain Craig said that he spoke as a junior member of the important committee managing the domestic affairs of the hospital, and he testified to the spirit of keenness and loyalty which prevailed among all with whom he came into contact, while he considered that the exploits in the athletic world of the comparatively small school were particularly gratifying because they were accompanied by a high average of success in examinations. The Dean commenced by recording the retirement from the active staff of two of its most prominent members, Mr. H. S. Pendlebury, who no longer was residing in London, and Dr. Cyril Ogle, who, although he was now on the consultant staff, retained control over a certain number of beds, through the courtesy of the succeeding senior physician, and was thus able to continue the clinical teaching which so many generations of students had followed. Dr. Feiling said that the school was now full, as it was not considered that adequate accommodation could be found for more than 100 or 110 students, and while he noted that Dr. Graham Little, in his introductory address, had warned them that all medical schools might expect a decrease in entry, he had no apprehensions on this score. He gave the examination results to show the high average level of success in examinations which the students at St. George's had achieved during the past year. In response to allusions made both by Captain Craig and Dr. Feiling, Mr. G C. Dewes, the captain of the cricket eleven, which had secured the inter-hospital cup, spoke amusingly of the failure of statisticians to prophesy success for an eleven from a small school against schools of the size attached to St. Bartholomew's or Guy's; he attributed the good-fortune of his team partly to their keenness and greatly to the generous action of Mrs. Tuke in providing the cricket ground for practice.

St. Mary's Hospital dinner was held at the Connaught Rooms on Oct. 4th, and attracted a large number of past and present students, including many who had been at the post-graduate course held at the hospital during the preceding three days. The Chairman, Dr. G. W. H. French, after referring to the death of Mr. Herbert Page, Mr. Clayton-Greene and other St. Mary's men, went on to speak of the affairs of the hospital and medical school, and commended the new appeal by which it is hoped to equip two new operating theatres, increase the number of beds, and improve the accommodation for nurses. He quoted examination results in which 54 per cent. of St. Mary's students had been successful, as compared with 29 per cent. of all the students entering; from this he deduced that the present students were working as hard as they were playing. Mr. A. R. Prideaux, chairman of the Hospital Board, said that it had caused the Board much anxiety that the hospital should have had to turn away urgent cases. The 44 new beds which they hoped to provide would enable them to reserve some for emergencies. The King Edward Hospital Fund had offered the hospital £4000 on condition that another £20,000 was raised before the end of the year. The hospital's reply had been to raise £20,000 in five weeks, the extra cost of this appeal being not more than £150. Efforts were being made to secure additional land beside the hospital for purposes of extension. Dr. C. M. Wilson, Dean of the Medical School, said that the entry of students at medical schools always increased after a war. In 1919–20 the entry at St. Mary's had risen to 45, just as it rose after the South African War. In 1921, however, it had fallen again to 31, and this return to pre-war level seemed to mark a crisis in the school's affairs, especially as expenses nowadays were four times as great as formerly. Clinical units had been started and during the past year the entry at St. Mary's had risen again to 45, whereas in other schools it had fallen. On the previous Saturday, he was glad to report, three Rugby fifteens had taken the field. Sir William Willcox, in proposing the toast of "The Chairman," said that no better man could be found to represent the general practitioner, who was the backbone of the profession and reached a higher general level in this than in any other country.

The annual dinner of past and present students and friends of the *Middlesex Hospital* was held at the Savoy Hotel on Oct. 1st. The Chairman, Mr. Victor Bonney, spoke of the new annexe of the hospital, which is now in full working order and is enabling the institution to carry on during the process of rebuilding with only a small diminution in the full numbers of beds for in-patients. Having referred in felicitous terms to the work done for the hospital and school by Sir Henry Morris, Sir Richard Douglas Powell, and Mr. Stephen Paget, whose deaths have saddened the past year, the speaker dwelt on the great schemes in progress. The site for the new Institute of Biochemistry is now clear, and it is hoped that the next 12 months will see the completion of this building, which the Middlesex owes to the generosity of Mr. Samuel A. Courtauld. Replying to the toast of "The Middlesex Hospital and Medical School," Mr. Courtauld alluded to his personal experience of the enormous importance of true scientific research in industry, and expressed his certitude that the selection and support of capable biochemical workers would lead to important advances in medical knowledge. Mr. Eric Pearce Gould, Dean of the Medical School, referred to the generosity of the old medical students of the school who have contributed more than £1000 towards the reconstruction fund. Sir Walter Fletcher, responding to the toast of "The Guests," expressed the admiration which he, as secretary of the Medical Research Council, felt for the constant output of valuable work from the research departments of the hospital. It was, he said, a pleasure to afford as much help as possible to an institution so admirably equipped and organised.

The annual dinner of *Westminster Hospital* students was held at the Royal Adelaide Gallery on Oct. 1st. The Chairman, Mr. William Turner, won applause by an announcement that he would not encourage long speeches, and the evening's entertainment was chiefly musical, the songs and recitations chosen being variously appropriate to the ages of the audience. In a short statement on the position of the medical school, the Dean, Dr. A. S. Woodwark, expressed himself as more than satisfied with its progress. The entry of students during the past year had been higher than during the previous 25, and he was confident that the numbers would increase still further. In this, its ninety-third year, the school was going ahead in every direction. That its facilities were being appreciated was evident from the fact that the War Office had chosen it as the place of post-graduate instruction for officers of the Royal Army Medical Corps, and there was no doubt that students would be attracted by the equipment of new laboratories, made possible by the John Burford Carlill Endowment; these had recently been opened by the Vice-Chancellor of the University of London. Dr. Coombes and Mr. R. Greene replied to the Chairman's toast of "Past and Present Students," Dr. Coombes recalling the days when visitors came and paid 1s. at the porter's lodge because they mistook the hospital for the Royal Aquarium. Dr. Brittan Gill proposed the Chairman's health and he briefly responded.

MEDICAL FREEMAN OF ANDOVER.—At a special meeting of the Andover Town Council on Oct. 1st the Honorary Freedom of the Borough was conferred upon Dr. E. A. Farr in recognition of his services as Mayor for three successive years and of the part he has taken in bringing to a successful issue the scheme for the new War Memorial Hospital, of which he is senior medical officer.

ROYAL DENTAL HOSPITAL OF LONDON: *School of Dental Surgery.*—The scholarships, prizes, and certificates awarded during the past academic year were presented on Oct. 4th by Sir Humphry Rolleston at the hospital. Mr. H. Stobie, the Dean, said that the number of students and pupils in the school is at present 135. Examination results for the year were as follows: Of 95 candidates for finals 53 passed; of 50 candidates for mechanics 37 passed; the corresponding figures for metallurgy being 47 and 33 and for dental anatomy 93 and 69. Sir Humphry Rolleston delivered an address on the Relation of Dental and General Hospital Schools. Discussing the desirability of union of dental and general hospital schools, he said that there were good reasons in favour of their close association. From the point of view of the patients there was much to be gained by consultation and an obvious advantage was the provision of beds for patients undergoing extensive extractions and operations on the jaws. In the interests of the progress of dental science correlation with other departments was important, and again the value to dental students of seeing the medical and surgical complications of dental disease was incalculable. The introduction of a compulsory medical qualification for all dentists was not practical politics at present, though it might be in the future. Meanwhile the more progressive institutions for the training of dentists were likely to ally themselves with general medical schools. For this reason Sir Humphry Rolleston suggested that the Royal Dental Hospital would also sooner or later be driven to unite with a general teaching hospital. Doctors would naturally send their sons and daughters who intend to take up dentistry to the dental schools attached to their old teaching hospitals, and dentists educated at dental schools which had remained in splendid isolation would sooner or later follow suit. This possibility was worthy of serious consideration. The recent amalgamation of the Rugby football clubs of the Royal Dental and Charing Cross Hospitals might be prophetic. Mr. Norman G. Bennett moved a vote of thanks to the speaker.

EDINBURGH ROYAL INFIRMARY.—On Oct. 9th the new radiological department is to be opened by the Duke of York.

ROYAL SOCIETY OF MEDICINE.—As we have already announced, the annual dinner of this society will be held on Thursday, Nov. 18th, at 7.30 for 8 P.M., at the Hotel Victoria, Northumberland-avenue, when the Prime Minister has consented to be the society's guest of honour if his duties permit. Those who desire to be present are asked to apply on the proper form at an early date, particularly as it may become necessary to limit the number of private guests. No places can be reserved after Nov. 11th.

ROYAL SANITARY INSTITUTE.—A sessional meeting will be held at the Town Hall, Dover, on Friday, Oct. 22nd, at 7.30 P.M., when Prof. H. R. Kenwood will take the chair at discussions on Diphtheria Immunisation (Dr. Joseph Cates and Major F. E. Roberts, R.A.M.C.) and Port Sanitary Administration (Dr. A. B. McMaster). Visits to local places of interest and a reception by the mayor have been arranged for the afternoon. Those proposing to attend should notify Dr. McMaster, at Brook House, Dover, by Oct. 15th.

CHELSEA CLINICAL SOCIETY.—The annual dinner of this society will be held at the Cafe Royal, Regent-street, on Tuesday, Oct. 26th, at 7 for 7.30 P.M., Dr. Ernest Young in the chair. Amongst those who hope to be present are Lord Carson, the Dean of St. Paul's, and Sir Arthur Conan-Doyle. Members are invited to bring guests, and application for tickets should be made to Mr. A. R. Thompson, 45, Queen Anne-street, W. 1. Further arrangements for the session include discussions on Encephalitis Lethargica on Nov. 16th, and Septicæmia on Dec. 21st.

MEDICAL SOCIETY OF LONDON.—The programme of the first half of the next session of this society has now been issued. The annual general meeting will be held on Monday, Oct. 11th, at 8 P.M., after which the Fothergillian Medal will be presented to Sir Gowland Hopkins, F.R.S., and the annual oration will be delivered by Sir Berkeley Moynihan on Before and After Operation. Amongst other arrangements are a clinical evening on Oct. 25th at 8 P.M., and discussions on Sternal Pain (Dr. John Parkinson and Mr. A. J. Walton, Nov. 8th, 8.30 P.M.), on the Treatment and Diagnosis of Bronchiectasis (Dr. Clive Riviere and Mr. J. E. Roberts, Nov. 22nd, 8.30 P.M.), and on the Exanthemata (Dr. J. D. Rolleston and Dr. R. A. O'Brien, Dec. 13th, 8.30 P.M.). The Lloyd Roberts lecture will be delivered on Friday, Nov. 19th, at 5 P.M., at the Royal College of Physicians by Dean Inge, whilst the Lettsomian lectures are arranged for Monday, Feb. 21st, and Wednesday, March 9th, at 9 P.M., the subject being the Surgery of the Spinal Cord and Membranes, and the lecturer Mr. Donald J. Armour.

EUGENICS EDUCATION SOCIETY.—This society has changed its address to 20, Grosvenor-gardens, London, S.W. 1; Tel.: Sloane 2086.

WEST LONDON HOSPITAL CHAPEL.—By the generosity of Mr. Dan Mason a chapel has been added to this hospital. It is dedicated to St. Michael and All Angels, and has just been consecrated by the Bishop of Kensington.

VICTORIA UNIVERSITY OF MANCHESTER.—The following candidates have been successful in the undermentioned parts of the examination for the Diploma in Public Health. Part I.: Mary Evans; Part II.: John Rigby and H. M. Turner.

GLASGOW CHILD WELFARE CENTRE.—On Oct. 5th Major Walter Elliot, Under-Secretary of State for Scotland and Vice-President of the Scottish Board of Health, opened a new child welfare centre in Springburn, Glasgow. This is a new unit in the large Glasgow scheme for child welfare.

BRUSSELS UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.—This association, which was formed 46 years ago in order to safeguard the interests of all medical graduates of the University of Brussels, will hold its annual dinner on Oct. 28th at the Langham Hotel, Langham-place, London, W., at 7.30 P.M. Any graduates in this country who have not received a notice of the dinner or a recently published list of members and rules of the association, are asked to communicate with the hon. secretary, Dr. A. D. Woolf, at 11, Chandos-street, Cavendish-square, London, W. 1.

MEDICAL TOUR OF THE FRENCH RIVIERA.—The Société Médicale du Littoral Méditerranéen has organised a visit of doctors from different countries to the French Riviera, in order to acquaint them with the therapeutic resources of this region. The tour will take place between Dec. 15th and 24th, and will include visits to Hyères, St. Raphael, Cannes, Grasse, Venice, Nice, Beaulieu, Mentone, Monte Carlo, and Monaco. The programme and full particulars can be had from the Office Français du Tourisme, 56, Haymarket, London, S.W.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Oct. 11th.—5 P.M., WAR. Presidential Address: Group-Captain Henry Cooper, R.A.F.: The Wider Aspect of Service Medical Work.

TUESDAY.—5 P.M., THERAPEUTICS AND PHARMACOLOGY. Presidential Address: Dr. George Graham: The Treatment of Gout.

THURSDAY.—8.30 P.M., NEUROLOGY. Presidential Address: Sir James Purves-Stewart: Intracranial Tumours and Errors in their Diagnosis.

FRIDAY.—8 P.M., OBSTETRICS AND GYNÆCOLOGY. Specimens: Prof. Louise McIlroy: (1) a Case of Bilateral Malignant Disease of the Ovary in a Girl of 18; (2) a Case of Endometrioma of the Ovary. Presidential Address by Dr. Archibald Donald. Paper: Mr. Victor Bonney: The Outcome of 214 Radical Abdominal Operations for Carcinoma of the Cervix Performed Five or more Years Ago. The paper will be discussed by Dr. Lockyer, Prof. Fletcher Shaw, Mr. Rivett, Mr. Gray, and others. —8.30 P.M., ELECTRO-THERAPEUTICS. Presidential Address: Dr. G. B. Batten.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Oct. 11th.—8 P.M., Annual General Meeting. 8.45 P.M., Presentation of the Fothergillian Gold Medal to Prof. Sir Gowland Hopkins. 9 P.M., Sir Berkeley Moynihan: Annual Oration, "Before and After Operation." Conversazione.

SOCIETY FOR THE STUDY OF INEBRIETY (Rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W.).

TUESDAY, Oct. 12th.—4 P.M., Dr. J. D. Rolleston: Alcoholism in Classical Antiquity.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Oct. 11th, to SATURDAY, Oct. 16th.—FELLOWSHIP OF MEDICINE (Special Lecture), Medical Society of London, 11, Chandos-street, Cavendish-square, W., Thurs., Oct. 14th, 5 P.M., Sir Thomas Horder on Some Emergencies in General Medicine.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross, W.C. Special demonstration on The Red Eye and the

Significance of Circumcorneal Injection by Mr. M. L. Hine on Friday, Oct. 15th, at 5 P.M. The lecture and demonstration are free to members of the profession.—CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C., Intensive course in Clinical Laryngology, Rhinology, and Otology. Operative class also.—LONDON SCHOOL OF TROPICAL MEDICINE, Endsleigh-gardens, N.W. Tues. and Thurs., 2 P.M., clinical demonstration. Further information from the Secretary of the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Oct. 11th.—2 P.M., Special Demonstration of Medical Cases in the Wards: Dr. A. J. Whiting. 2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.
WEDNESDAY.—2.30 P.M. to 5 P.M., Medical Skin and Eye Clinics; Operations.
THURSDAY.—2 P.M., Special Demonstration of Surgical Cases: Mr. H. W. Carson. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.
FRIDAY.—2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

POST-GRADUATE HOSTEL, Imperial Hotel, Russell-square, W.C.
TUESDAY, Oct. 12th.—9 P.M., Mr. J. P. Lockhart-Mummery: The Prognosis of Rectal Cancer.
THURSDAY.—9 P.M., Mr. R. E. Elmslie: Internal Derangement of the Knee-joint.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Oct. 12th.—5 P.M., Dr. S. E. Dore: Physiology of the Skin.
THURSDAY, Oct. 14th.—5 P.M., Dr. J. M. H. MacLeod: Morphology and Histopathology of Elementary Lesions.

NATIONAL HOSPITAL, Queen-square, Bloomsbury, W.C.
MONDAY, Oct. 11th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Adie: Disseminated Sclerosis.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Bernard Hart: The Psychoneuroses.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Martin: Epilepsy.
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Symonds: The Pathogenesis and Treatment of Cerebral Vascular Disease.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street.
THURSDAY, Oct. 14th.—4 P.M., Dr. Nabarro: Meningitis in Children.

ST. MARGARET'S HOSPITAL FOR WOMEN, Acomb-street Whitworth Park, Manchester.
WEDNESDAY, Oct. 13th.—4 P.M., Dr. H. R. Clarke: Pitfalls in Medical Practice.

ANCOATS HOSPITAL POST-GRADUATE COURSE.
THURSDAY, Oct. 14th.—4.15 P.M., Mr. Harry Platt: Treatment of Common Injuries.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Oct. 12th.—4.15 P.M., Dr. W. Fletcher Shaw: Chronic Pain in the Lower Abdomen.
FRIDAY.—4.15 P.M., Prof. J. Kay Jamieson: Lymphatic System in Relation to Cancer.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.
TUESDAY, Oct. 12th.—4 P.M., Prof. MacWilliam: High Blood Pressure from the Physiological Aspect. Discussion to be opened by Prof. Herring.

Appointments.

GRANT, J. W. GEARY, F.R.C.S. Eng., has been appointed Honorary Surgeon to the Cardiff Royal Infirmary.
JOE, A., M.D. Edin., D.P.H., Medical Superintendent, North-Western Hospital, Hampstead.
PAGE, C. MAX, M.B., M.S. Lond., F.R.C.S. Eng., Consulting Surgeon; and RUSSELL, H. B., M.D. Lond., Deputy Physician.
Certifying Surgeons under the Factory and Workshop Acts: LOGIE, J. M., M.B., C.M. Glasg. (Burntisland, Fife); YOUNG, J., M.B., Ch.B. Glasg. (Ormskirk, Lancaster).
Scotland Yard: CASSIDY, M.A., M.D. Camb., F.R.C.P. Lond., Physician and Chief Medical Officer.

Vacancies.

For further information refer to the advertisement columns.
Barbados General Hospital.—Senior Res. S. £300.
Belfast, Queen's University.—J. C. White Lectureship in Bacteriology. £600.
Bethlem Hospital, Lambeth-road, S.E.—Non.-Res. H.P. £25 per quarter.
Birmingham, Queen's Hospital.—Asst. Obstet. Officer. £50.
Bloomsbury Dispensary, 12, Bloomsbury-street, W.C.—Surg. 100 guineas.
Bristol Mental Hospital, Fishponds.—Third Asst. M.O. £350.
Bristol Royal Infirmary.—Hon. Gynæcological Reg., Hon. Ophth. Reg., and Asst. Anæsthetist.
Cambridge, Addenbrooke's Hospital.—H.P. At rate of £130.
Cardiff, Royal Infirmary.—Hon. Asst. S.
Chichester, West Sussex County Mental Hospital.—Med. Supt. £900.
Croydon County Borough.—Asst. M.O. £600.
Derbyshire Royal Infirmary, Derby.—Two H.S.'s and Asst. H.S. and Cas. O. Each at rate of £150.
East London Hospital for Children and Disp. for Women, Shadwell, E.—Res. M.O. £200. H.P. and Cas. O. At rate of £125.
Gloucestershire Royal Infirmary and Eye Institution, Gloucester.—Sen. H.S. At rate of £175.
Guildford, Royal Surrey County Hospital.—H.S. £150.
Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—H.P. and Cas. M.O. Each at rate of £100.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Pathologist, &c. £750. Also H.P. £50 for six months.
Leeds, St. James' Hospital, Beckett-street.—Chief M.O. £1000
Manchester, St. Mary's Hospital.—Two H.S.'s. Each at rate of £50.
Metropolitan Hospital, Kingsland-road, E.—Sen. H.P., Sen. H.S., Jun. H.P., Jun. H.S., and two Cas. O.'s. All at rate of £100.
Middlesex Hospital, W.—Phys. and Asst. Phys.
Nordrach-on-Mendip Sanatorium.—A.M.O.
Otago Hospital Board, Dunedin, N.Z.—Med. Supt. £1000.
Otago University and Dunedin Hospital, New Zealand.—Medical Tutor and Sen. Res. M.O. Also Sen. Res. Surg. O. Each £400.
Portsmouth Royal Hospital.—Third H.S. and Cas. O. At rate of £150 and £100 respectively.
Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Cas. O. At rate of £100.
Royal Chest Hospital, City-road, E.C.—Res. M.O. At rate of £150. H.P. At rate of £100, and Anæsthetist. 10 guineas.
Royal National Orthopædic Hospital, 234, Great Portland-street, W. Surg. Reg. 100 guineas.
Royal Northern Hospital, Holloway, N.—H.S. and H.P. Each at rate of £70.
Salisbury General Infirmary.—H.S. £150.
Staffordshire General Infirmary, Stafford.—H.S. At rate of £200.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Cas. O. and Reg. £150.
Walsall General Hospital.—Sen. H.S. and Jun. H.S. At rate of £200 and £125 respectively.
West End Hospital for Nervous Diseases, Welbeck-street, W.—Hon. Reg.
The Chief Inspector of Factories announces a vacant appointment for a certifying Factory Surgeon at Tunbridge Wells (Kent).

Births, Marriages, and Deaths.

BIRTHS.

DAVIES.—On Sept. 27th, at The Gables, Chipping Campden, Glos., the wife of Dr. J. C. Davies, of a daughter.
SIMPSON.—On Oct. 2nd, the wife of J. Watson Simpson, M.B., Ch.B., D.P.H., of Snitterfield, near Stratford-on-Avon, of a daughter.

MARRIAGES.

DENNEHY—MANSON.—On Sept. 23rd, at St. Edmund's Church, Bury St. Edmunds, Dr. John J. Dennehy, to Blanche Veronica Vivian Manson, daughter of the late Captain E. E. M. D. Manson, South Lancs Regt., and of Mrs. Manson, of North-gate, Bury St. Edmunds.
RANNIE—BROOKE.—On Oct. 2nd, at Holy Trinity, Sloane-street, S.W., James Rannie, M.D., to Mary Elaine (Molly), elder daughter of Mr. and Mrs. Norman Brooke, of Sidmouth, Devon.
SLATER—HOWE.—On Wednesday, Sept. 29th, at Rochester Cathedral, John McDonald S. Slater, M.B., F.R.C.S. Edin., elder son of Mr. and Mrs. W. H. Slater, of Murrayfield, Edinburgh, to Dorothy Rose, only daughter of Mr. and Mrs. T. E. Howe, of "The Clearing," Maidstone-road, Chatham.
STUBBS—HINTON.—On Sept. 30th, at St. Michael's Church, Shepton Beauchamp, Somerset, Major John William Cotter Stubbs, D.S.O., M.C., R.A.M.C., to Mabel, eldest daughter of the late Lieut.-Colonel C. B. Hinton, C.M.G., Royal Artillery, and of Mrs. Hinton.
WILSON—REES.—On Sept. 28th, at Roupell Park Church, S.W., Archibald Wilson, O.B.E., M.C., M.B., Ch.B., to Gwendolen, youngest daughter of the late Rev. Allen Rees, LL.D., of Ipswich, and Mrs. Rees, Streatham Hill, S.W.

DEATHS.

BALL.—On Oct. 2nd, at Stert-street, Abingdon, Berks, James Barry Ball, M.D., F.R.C.P., aged 77.
BARNETT.—On Oct. 2nd, at Hilgrove-road, South Hampstead, Lawrence Barnett, M.D.
EWART.—On Sept. 29th, at his residence, North-street, Chichester, David Ewart, M.D., F.R.C.S. Edin., O.B.E.
KING-LEWIS.—On Sept. 29th, at St. Lawrence, Jersey, James King-Lewis, M.R.C.S., L.S.A., formerly of Westbury, Salop, aged 65.
MORROW.—On Oct. 2nd, at the Middlesex Hospital, of acute lymphatic leucæmia, David Morrow, M.R.C.S., L.R.C.P., L.S.A., of Harley-street, W.
PERRIN.—On Oct. 3rd, at Temple-square, Aylesbury, Thomas Perrin, M.D., M.S. Lond., F.R.C.S. Eng.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE NERVOUS CHILD

Being an Abstract of Lectures given at the Teachers' Vacation Course at Bingley, Yorkshire, on August 9th and 10th, 1926,

BY MILLAIS CULPIN, M.D. LOND., F.R.C.S. ENG.
LECTURER ON PSYCHONEUROSES, LONDON HOSPITAL MEDICAL COLLEGE.

AN important point of view is involved in the title of these lectures. Nerves are things that we can see and handle, can put on a plate or under a microscope, and disease of them is called nervous disease; but the word "nervous" in this title is used in a totally different sense—a sense which Dr. Johnson, in a letter to Mrs. Thrale, described as incorrect. The usage of years has not made it more correct, but the misuse is so established that we must accept it, whilst bearing in mind that it involves not only inaccuracy but, to some extent, a wrong attitude.

We take for granted that man knows little of what goes on inside his body and is not responsible for such internal happenings, but we have assumed that we know all that takes place in our minds, and we cannot admit that our thoughts or feelings or emotional reactions are not wittingly determined by ourselves. Hence, when these processes are disturbed we maintain our assumption by placing the disturbances in the category of bodily events, and advertisements of patent medicines "for the nerves" indicate the commercial possibilities of the belief that to be nervous means to have one's nerves physically deranged. But there is a dim suspicion that all is not so simple; to be highly strung is almost commendable, to have a nervous breakdown or suffer from neurasthenia is pardonable, but by some subtlety of etymology to be neurotic involves moral censure. In these conditions we know nothing of any change in nerve tissue, though hypotheses which soon lead into the deep sea of metaphysics are common enough. The word nervous survives in the sense used in the title because it avoids, not metaphysics, but the admission that we are dealing with a problem not of body but of mind.

Perhaps the admission hurts our pride. Each one of us, nervous or not, likes to feel "I am the captain of my soul." But another reason for avoiding it is the difficulty of the problems thus created. As long as the nervous patient, his friends, and his doctor can meet the situation by a rest-cure or something to be taken three times a day—well, the situation is being met and no difficult problems are raised. Although a medical woman recently published a paper showing that one-fourth of all long illnesses amongst school-teachers fall into the group of "nervous breakdowns," and although a similar proportion exists in other occupations, yet no medical student at his qualifying examination expects to be asked about these disorders. If the problem of nervous troubles is thus avoided you may understand my diffidence in approaching that part of it—the nervous child—which contains the core of its difficulties.

What is Nervousness?

Whilst not assuming an antithesis between body and mind, I must indicate what appears to be our attitude to these conceptions. We picture the body as a set of mechanisms—bones, muscles, nerves, glands, and other tissues—which we can study in detail. But when we consider the behaviour of the individual we note various thoughts, feelings, and desires which we recognise in ourselves and assume in others. These processes we conceive as mind, though you will soon see that this conception must be enlarged. In a nervous person we must assume an impulse or inhibition that leads to behaviour ill-fitting to the situation; we often note, also, an unduly emotional state. Moreover, we may make a grievous error if we assume that the cause of the impulse, of the inhibition, or the emotion is known to the subject.

Mal-adapted behaviour and an apparently uncalled-for emotion are, then, characteristic of nervousness.

The Physical Side.

There are well-known bodily concomitants of emotion. Take, for example, that of fear. The pale face, rapid pulse, and altered breathing, the dry mouth, the tremor or immobility indicate a disturbance of bodily processes, and there are less obvious changes in the secretions of internal organs. A good deal can be said for the Lange-James theory that our perception of all these changes constitutes what we feel and describe as emotion.

But we are too ready to consider emotion as an acute experience. In the child who suffers from a continued state of apprehension there may be a general physical ill-being with digestive or circulatory troubles, loss of appetite, poor sleep, and such like. The resulting inability to cope with current difficulties sets up a vicious circle which demands attention both to the mental and the physical state.

The nervous parent has nervous children, not by heredity but by infection. Yet there is an inborn temperament related to physical development and especially to the development of certain glands. To take extremes as examples we know the cretin, stunted in mental and physical growth, who reacts in a marvellous way to the administration of extracts of the missing thyroid gland. Disease of the pituitary gland may lead to obesity and mental retardation, and other glandular disturbances may lead to premature or delayed sexual development. There is, within normal limits, a wide range of temperamental differences, and if any individual becomes nervous the kind of nervous reaction will be determined by his temperament.

Nervousness can produce physical symptoms, but the sequence may be mistaken, so that the nervousness is regarded as caused by the physical trouble. Bodily troubles *can* initiate nervous symptoms, but I regard that process as a setting free of possibilities already present. Sleepy sickness is followed by nervous symptoms and even serious delinquency, and in this disease there are actual changes in the brain, but, since all the symptoms are known apart from any brain change, their appearance may be regarded as the result of the removal of the control of the higher centres, which allows potential troubles to become manifest. A general malaise, like that induced by infected tonsils, may cause a child to give way to tendencies which better health would enable him to control. I am, however, sceptical about errors of refraction producing nervous symptoms. Defective sight may have an indirect influence, but I regard eyestrain as a bogy, and the only justification for condemning a child to wear glasses is the fact that he cannot see properly without them.

A continued state of apprehension can produce circulatory changes as shown by cold and discoloured hands, rapid fatigue, and in adolescents by faintings, breathlessness, and other symptoms that lead to the suspicion of heart weakness. Loss of appetite with nausea or actual vomiting can also arise. What is cause and what effect may be a difficult and important question. The symptoms, arising from a difficulty of adjustment, may be used as a means of escaping that difficulty and thereby become perpetuated. The *aim* of a neurosis, at any age, is often obvious to the outsider but hidden from those closely concerned with the patient. Even a mental symptom like night terrors serves the purpose of enforcing the presence of a loved person. Everyone may not find it easy to imagine night terrors maintained by such an aim, but I present the idea as a possibility.

There is a relation between an emotional state and posture. Note the child who stands with drooped shoulders, excessively curved lumbar spine, and protruding abdomen, and perhaps shows the faint blueness of the hands that marks a poor circulation. That child finds life's burdens heavy, is over-dependent, and often querulous. The stance is, I believe, the precursor of a condition found in the nervous adult and associated with a sagging of the abdominal contents which leads to diagnoses of movable kidney, dropped stomach, and the like.

Dietetic dislikes carry a good deal of emotion and are linked with bodily reactions. Though I would not advise forcing upon the child an article of diet which arouses repugnance, yet such dislikes should be discouraged; moreover, an adult who takes pride in his or her—it is generally her—dietary idiosyncrasies probably has other idiosyncrasies which make her unsuitable for a position in which children may find example and influence.

Squint, stammering, and left-handedness are related. They occur in families and a "cure" of left-handedness is often followed by a stammer. Stammer is recognised as a nervous sign, squint has been noted to occur in children of unstable disposition, but left-handedness has been regarded as a manifestation of original sin—in the child, that is—for the left-handed adult has been welcome in the team since the time when among the children of Benjamin "there were seven hundred chosen men left-handed; every one could sling stones at a hair's breadth and not miss." The left-hander is in general self-assured, obstinate in a quiet way, yet not given to futile opposition, and has a desire for justice for himself and others; he goes his own road with as little fuss as possible. Whether this results from the left-handedness or whether the left-handedness is adopted as a symbol of independence, I do not venture to say. Apart from scriptural authority, we have an inkling of the traits of the left-hander. In choosing as a companion in a tight corner between a stammerer, a squinter, and a left-hander most people would choose the last. For an example of grim determination I commend the biblical story of Ehud, "a man left-handed."

The familial occurrence of the three affections indicates differing reactions to parental authority or even to family

tradition. A left-handed father may be so kindly, calmly, and persistently obstinate that reaction in the children is inevitable.

Theory of the Unconscious.

This theory is essential to the understanding of nervous reactions, and we may approach it by looking at a phenomenon which, because it is universal, we accept as not calling for explanation. This is the loss of memory, or amnesia, for our early years. We say that we were too young to remember, but the memory of a child of 3 can easily go back for a year or more. The child has no defect of memory; it is we who are too old to remember.

There is a well-known saying attributed to Ignatius Loyola: "Give me the child to the age of 7 and I care not who has him afterwards." The foundations of character are laid in those early years, and all of us are influenced by mental processes once conscious, but now inaccessible to ordinary introspection. What has happened to those memories? We might regard character traits as determined by particular combinations of nerve elements and the continued use of certain nerve paths. This is a simple hypothesis, but it is not helpful except so far as it offers an explanation of training. Let us take an example. A girl of 10 breaks out into unreasonable anger on being denied any trivial thing, but quickly recovers and offers whatever atonement is within her power. Plainly a neurotic reaction. The parents, set to trace its first appearance, recall that at the suckling stage the maternal supply was deficient and the baby did not thrive. She always turned away from the breast with an outbreak of angry crying, and when put on artificial food repeated the action at the end of each feed, though by all the canons of child-rearing she had had enough. This reaction has persisted in unbroken sequence to the age of 10 and may become a permanent character trait. One might call it a conditioned reflex and speculate about nerve paths and nerve patterns. But, knowing how we blot out early memories, what support have we for denying that memory in some form independent of words has been at work throughout the history just given? Unless we suppose a radical discontinuity a change from reflex mechanism in the nursing child to a different world of memory a few months later, it seems reasonable that there was some mental link between the first reaction and those that occurred later, a link of the nature of memory.

Now let us make a fresh start from another direction. Doctors who treated men suffering from those mental breakdowns called shell-shock found in them losses of memory for emotional events, chiefly of war; these losses could be restored, and the restoration aided in the removal of symptoms which often symbolised in curious ways the incidents forgotten. Sometimes there were discovered losses of memory going back to the time of childhood.

These observations could best be summarised by the theory of the unconscious, first practically employed by Freud in regard to psycho-analysis. His early methods resembled those employed in reviving war memories, and experience of war cases has led to further work which has compelled many of us, almost against our will, to accept Freud's ideas to a greater or less degree. Chief among them is the conception of infantile memories which, with many later additions, remain in the *unconscious*, not as inert impressions but as a source of impulse and emotion that govern our likes and dislikes throughout life. Now you can see how the problem of the nervous child is the core of the problem of nervousness.

In this the emotional relationship of the child to the parents is an important element. It is in many respects composed of opposites—the desire to remain the child and to grow up, to obey and to disobey, to be dominant and to be submissive; these are further complicated by the fact that repression into the unconscious is constantly taking place. With growth the attitude to the parent is transferred to other objects and many mishaps may occur. Lack of affection may lead to a "sour grape" feeling towards the world at large, and a common type of nervous adult is one incapable of giving affection and, therefore, of receiving it, the situation being met by some of the many ways in which the nervous patient can use the neurosis to tyrannise over the personal environment. Too great an attachment can be as disastrous. Everyone is familiar with the mother's darling, and from my war experience I concluded that he generally suffered from shell-shock. A certain amount of "standing up to" the father is a developmental necessity, and the mother's darling escaping this need fails to stand up to anything. The same result may follow the influence of a drunken, bullying, or overpowering father.

Sex Instruction.

We must return to the fact that fear is important in the nervousness of the child, and here it has required the courage of the psycho-analysts to speak plainly of one source of that fear. They are accused of emphasising sex; but our reactions to that emphasis are so emotional as to remove themselves from the intellectual sphere and take their place among the results of unconscious influences which, in this case, are easily traced. The taboo against mention of sex has been mitigated of late years, but it still falls with full force upon the child, just as it fell upon us in our impressionable amnesic years with the result that we have accepted it as unquestionable.

Not only is the child assumed to have no knowledge of sex and reproduction, but knowledge must at all costs be withheld. The result is within the experience of many of us. There is set up a barrier behind which the child builds up a mass of speculation and distorted actuality, whilst we on the adult side of the barrier pretend that nothing is happening. Any sign the child may show of interest or knowledge is met with an emotional disapproval which quickly repairs any breach. What nervous development takes place behind the barrier depends upon the temperament of the child.

Here let me digress and briefly sketch temperamental types. Two extremes have always been known, the doer and the thinker, and these Jung calls the introvert and extrovert. The extrovert is in close contact with the world—he *feels* himself in contact and gives it no thought. Easily adjusted to his environment, he accepts the current view, has no doubts about the truth of his beliefs—though he can easily alter them—and, conforming to the social standard, is free from embarrassment or fear of criticism. The introvert has to make contact by thinking, he finds adjustment an effort, is critical of current views and his own, and tends to be overscrupulous and fearful of what people may think of him.

Their reactions to the taboo are quite different. The extrovert child will accept the situation, will find pleasure in the search for illicit knowledge, will enjoy the nasty jest, and, generally speaking, will come through unharmed. And on reaching adult life he will again adjust to the social standard and resolutely withhold information from his offspring.

The introvert cannot accept the taboo without thought; he decides—as far as he can decide—that, since the omniscient parents head him off with prevarications or untruths, there must be something dreadful in this knowledge, and something dreadful might happen if he pried into it. Hence he will turn a deaf ear to the talk of his fellows; he turns a deaf ear, but the talk sinks into the unconscious to plague him with a sense of sin. The impulse of curiosity is strong and he is compelled to build up phantasies about the mystery; these phantasies likewise are repressed with any knowledge he may have gained. And when he becomes a parent he will know that his children should be better instructed; but he will not have the courage to instruct them, for the introvert at any age has his fears stimulated by the sex taboo. (I think we are justified in using this designation. A taboo in its original or South Sea Island sense was essentially irrational and was supported by public opinion, whilst its violation was expected to bring about the most direful social results.)

How secretive behaviour can influence the child may be illustrated by an experience of my own, which I have recorded elsewhere,[1] as follows:—

> A girl of six, usually truthful, lost a playmate by death; the parents, for reasons which seemed good to them, withheld this information, but friends discussed it before her in hushed voices in the trustful idea that she would not understand. Then a pet animal of hers died and, looking at the dead body, she said to her father: "Isn't it strange that when an animal dies it's here, but when a human dies it isn't here?" The father guessed that she was speculating about the death of her young friend and decided that she must be told the truth. Her mother gave her the news, which was met with a burst of tears and "She can't be dead, mummy, she was too young." But after a minute's thought she repeated the same words about the dead animal—to her mother, of course, this time. The father, confirmed in his suspicion, asked her later if she knew of the death of her playmate before her mother told her. This question was met with "Of course I didn't, how could I? Why do you ask me?" and the father's attempt to explain why he asked only brought forth more denials. It would have been impossible to discover what fantastic ideas about death were present in the mind of the child, who, recognising that knowledge of a mysterious happening was hidden from her, retired into her own world and refused to part with its secrets. The analysis of adults, however, shows that such incidents form the constituents of unconscious phantasies which may attain great importance in later life.

Let us consider what was imposed upon this child. When the death was discussed she was obliged to act the lie of not understanding, and in doing that she had to keep considerable emotion in check. Then she had to defend herself against the implication of having acted several lies, and did it by telling fresh ones. In regard to the sex taboo many—indeed, most—children are under the necessity of maintaining a similar false standard of thought and action, though we must remember that all is not on the plane of full consciousness. Moreover, when the parent is the owner of knowledge

[1] The Nervous Patient. Lewis and Co. Pp. 28.

which must not be sought, and which the child is yet impelled to seek, the fear of the forbidden becomes displaced upon the parent. This may explain those cases in which a parent free from any trace of harshness is, nevertheless, an object of the child's fear or timidity.

It may be said that I am beating the air, that the modern parent agrees that the child should be saved from the pitfalls of ignorance. There are, indeed, books with such titles as "What a boy of 12 ought to know," and it has been proposed that upon school-teachers should fall the task of instruction. But before the taboo is crowned by an initiation ceremony does anyone try to find out what the boy of 12 really knows? To try is to fail. "Give me the child to the age of 7" said Loyola, and for more than seven years the boy—and all this applies, of course, to the girl as well—has been influenced by false ideas and false values. The matter is not one of knowledge versus ignorance, but of the emotion with which the subject is invested. Those, for instance, who feel that they would not dare to discuss this subject before other people as I am doing had better avoid any attempt to deal with the problem in the child until they have dealt with their own; then they may find that there is no problem except within themselves.

There is no difficulty in stating conventions and having them accepted. That certain subjects are not spoken of in general talk is a proposition that needs no emotional emphasis, and the principle of avoiding such emphasis should be widely applied. The more emotional we make a prohibition the more we drive into the unconscious whatever tendency there may be to violate that prohibition, and what is driven into the unconscious is placed beyond conscious control. Take, for example, our emotional attitude to swear-words. No one goes through life without hearing them, and in adult neurotics words regarded as obscene often thrust themselves into consciousness as obsessive thoughts. Or consider the delight the small child takes in strutting about naked; I think that delight is a matter of observation. Suffered for a time, it soon meets with the taboo against exposure, enforced with unexplained emotional emphasis. One result is the dream most of us have experienced of being insufficiently clothed in public, a dream often of nightmare intensity. Another result is the persistence in the unconscious of a tendency to expose the body or to play Peeping Tom with the opposite of extreme modesty in consciousness. Incidents caused by the out-cropping of this unconscious tendency are, unfortunately, common and often have serious effects upon young people, effects which are in direct proportion to the emotional emphasis placed upon the prohibition.

The period of infantile amnesia is occupied largely by the enforcement of social prohibitions. Please do not credit me with attacking these—they have to be accepted. But whilst enforcing them as "things that are not done" we can avoid the attitude of the savage towards those who would violate the tribal taboo. That attitude is not felt to be necessary in matters of great difficulty. The habit of wiping muddy boots upon the door-mat, for example, may need disciplinary measures for its cultivation, but, however severe the discipline, we do not invest a lapse with the feelings of horror and awe that we attach to violations of taboo. Hence, however painful may have been the acquirement of the door-mat habit, it rarely serves as a basis for nervous symptoms.

The Masturbation Difficulty.

I should not be doing my duty if I avoided the subject of masturbation. A physician monk named Tissot once wrote a volume in which many physical ills were ascribed to this practice, and his statements have been copied through the centuries, whilst only of late years have physicians had the courage to admit that we know of no physical ills that result from it. It does not produce insanity or consumption, nor does it per se induce the nervous troubles we are concerned with. It is so common that the race would be in a bad way if a tithe of the evils ascribed to it really existed. Great remorse is frequently felt often associated with persistence of the habit, and on account of the many superstitions about it the sufferer who seeks help is likely to have that remorse intensified. At the risk of incurring censure I will state plainly that when I have to deal with this remorse my first advice takes the form of "Don't worry, most people have gone through it," for the removal of the remorse is the best road to the dropping of the habit. The ill-effect lies first and foremost in the guilt feeling, then in the fact that it is a most selfish action and turns inwards mental energies that ought to flow outwards. Moreover, the psychic trends that may be established in connexion with it—in the shape of perverted phantasies and the like—may stand in the way of a healthy mental attitude in later life; but the phantasies are not caused by the habit, though they become linked with it.

I have seen cases in which preventive measures have been disastrous. One of a young man whose serious neurosis hung upon his being trussed up at night in a weird instrument designed to prevent the habit; another in a girl who could not learn, though her intelligence was good. At my only interview with her she quickly told her story, with the pathetic excuse "I only do it when I am nervy." But her mother watched her day and night in her efforts to stop the habit, to which she attributed the troubles really caused by her own treatment of the situation.

The impulse to the act may be successfully controlled; when repressed and denied conscious recognition it may show itself (as described by Maurice Healy in his book "Mental Conflict and Misconduct") in delinquencies like truancy, kleptomania, and such a bizarre symptom as the impulse to leap into an unattended cart and drive away.

The Handling of the Nervous Child.

Emotion is infective, and the fussy parent or teacher can easily induce fear in the child; in fact, almost any neurotic symptom can be passed on. A lack of affection, whether real or only fancied, can lead to the "sour grapes" feeling which makes the child reject all attempts at friendly relations. Truculence and outbreaks of temper have to be checked, but if we have grasped the conception that the child may not be aware of the *why* of his own reactions we shall not resort to retributive punishment but rather avoid the stimuli that produce them and make as easy as possible the passing of the storm. But please do not assume that a belief in unconscious motivation means the rejection of measures that encourage the child to behave as he should. Impulses not consistent with the demands of reality should be overcome, whatever their origin. We all have them.

School life, by removing the child from the surroundings in which nervousness has arisen, is often the best for him, and for an only child the rough and tumble of school life is a necessity. Faults in emotional development are likely to crowd upon him. The neurotic demands that a child makes upon the parent can rarely be fulfilled at school, and these demands show themselves in extraordinary guise. I know an only child who was a model of obedience in circumstances when obedience might have been difficult. But her constipation was the plague of her mother's life. At last she went to boarding school, taking with her a packet of senna leaves which were to be handed over to the school authorities with full directions for their administration. The leaves were burnt and the child's intestinal functions were left to look after themselves, which they did quite efficiently. The girl doubtlessly derived gratification from the symptom which, by its obstinacy, counterbalanced the obedience she so readily gave in other directions.

But for one type of child the rough and tumble may be most distressing. The school-child is mainly an extrovert—introversion increases with age—and the extreme introvert may have an unhappy time. The extrovert despises the other, who fears and yet envies him. The introvert—fearful, over-conscientious, and subject to all kinds of inhibitions—may fail to adapt to school and retire more and more into his own world. You may remember that about a year ago a boy at a public school committed suicide. The newspaper accounts showed him to be an extreme introvert, and a realisation of his temperamental difficulties by someone in a position to help might have prevented the tragedy.

The introvert teacher may suffer when facing the mass extroversion of his scholars; his doubts and over-scrupulousness will appear as vacillation and fussiness, but insight into himself will help him with the sensitive child when his opposite type might fail.

Whether child or grown-up the sufferer from a pathological fear or inhibition realises the absurdity of it. To laugh at it or force him to face it without sympathy is futile. The only way—short of special treatment—is to recognise it as of real importance, to assure him of that recognition, and then encourage him to carry on in spite of it. One of his character traits is reticence, and yet talking about his symptoms may greatly help to remove them. If you wish to get the confidence of the nervous person, child or adult, you must remember that he is overwhelmed by considerations of moral judgment, and if you show any signs of judging you will stop the flow of confidence.

One need not think the extrovert child escapes nervous troubles, but they are less likely to be complicated by his emotional view of them. He may show apparently isolated symptoms or present educational difficulties in the face of which he shows a cheerful detachment in contrast to the worrying reaction of the other.

I feel that I have left the subject rather in the air by dealing with principles instead of specific difficulties. I might have talked about the obvious, about regular meals, early hours, the avoidance of excitement and overwork, of the sin of frightening a child, and such like. But that was not what I set out to do. Perhaps the most important point I have tried to make is that we adults have to look into ourselves to find the cause of nervousness in the child.

PREVENTION OF VENEREAL DISEASE IN THE FRENCH ARMY.

IN France venereal disease is held by many to be not a subject for public discussion, but the recruit when accepted is given a preliminary pamphlet of information, a second when he is ordered to join his unit, and a third when he arrives in barracks, where, during his service, his officers and N.C.O.'s, and the regimental medical officer, all have chats with him and advise him, at the same time studying him to decide if he will make a good instructor for those who will follow him. Then there are notices in barracks and in the canteen, books in the regimental library, and various moral agencies. Certain police measures protect the recruit; women soliciting in the neighbourhood of barracks or in public-houses are arrested, also those suspected of having infected men. Major H. M. G. Jausion, of Val-de-Grâce, who offers much instructed comment in the *Archives de Médecine Militaires* for July, states that ablution cabinets, as advised in the United States, have been installed in barracks, but they are thought to have made little difference, and reliance is now placed on prophylactic packets of which there is a free issue available in barrack rooms. Men who are attacked are sought out at inspections, they are isolated and treated; uncomplicated gonorrhœas in the regimental infirmaries, those with complications in the urological sections of hospitals, and the syphilitic cases in the special wards of hospitals. Ulcers are not to be kept in regimental infirmaries, not even for making diagnosis sure; it is so important to begin treatment at once that they must be sent forward directly. These men are all taught the essential need for prolonged treatment. The bearing of early treatment on the time when marriage may be allowed is carefully considered in this paper, in which is also mentioned a method of administering arsenobenzol by the mouth. As in other armies, it is allowed that statistical facts about the success of prevention are difficult to secure.

A CONTORTIONIST.

THE trade of the contortionist in this country seems almost to have died out except for occasional street performances, and these are not always exhibitions of true skill and dexterity. On the other hand, there exist a large number of people, acrobats and ordinary folk, who claim to be "double-jointed." What this term means is not altogether clear. In many cases it means that owing to congenital laxity of the capsules or malformation of the articular surfaces certain joints may be partially dislocated at will. Whether this covers all cases of "double joints" and whether the ability can be acquired are some of the questions suggested by the appearance at various halls of entertainment in this country of Mr. Chester A. Kingston, who is an unusually supple contortionist. His father and mother were acrobats and contortionists, and he claims that the amazing pliancy, especially of the spinal column, is due entirely to training in very early life. A slight funnel-shaped depression of his sternum and a definite Harrison's sulcus suggest that possibly there were other factors. Although well over medium height and of a fine degree of muscular development he manages to get into a small box measuring 16 in. by 19¼ in. by 21 in. He also passes himself through hoops and backs of chairs fairly easily. Mr. Kingston was examined by certain members of the French medical profession during a recent visit to Paris, and while in London he has been X rayed at the Middlesex Hospital. Screen examination showed that an amazing rotation of the arm, for example, was not in the nature of a dislocation of the shoulder, but to a very remarkable range of scapula movement. X ray examination of some of Mr. Kingston's most remarkable positions was impossible for technical reasons, but attempts were made to get views of his vertebral column and also of his hip-joint, which present interesting features under the screen.

ADVERTISING HEALTH.

Mr. T. Crew, clerk to the Leicestershire Insurance Committee, has written a book called "Health Compendium and Health Publicity" (the Reader Printing Co., Sanvey Gate, Leicester. Pp. 260. 7*s.* 6*d.*) which gives a brief account of most of the societies working for the advancement of health in this country. The information is conveniently arranged for reference, and has a foreword by Prof. A. Bostock Hill, as well as short articles by Dr. C. J. Bond on Mental Hygiene, and by Dr. David Kirkhope on the Baby Week Movement.

"The problem before us to-day," says Mr. Crew, is "to interest the adult population, who, in many cases, are ready to believe that all health matters should be left to the constituted authority to deal with." He points to the tremendous success of commercial men in making people want things they have not wanted before, and considers that in "advertising health" the film and the poster are of immense value. The message of the poster may be either by words or pictures, but it must be bold and simple; Mr. Crew believes in the "small distinctive poster." Every page of his book is headed with a slogan—such as Bacteria Don't Like Soap—and the series is useful, though some of the examples would hardly be acceptable to the medical purist. Even more interesting, however, are the many reproductions of British and foreign posters used in health propaganda, and those who have to organise Health Weeks and the like will do well to look at them.

What is known about physiology and pathology does not always lend itself to didactic mass-instruction, and it is easy to criticise popular teaching on the ground that truth is often sacrificed to symmetrical theory. Moreover, as Prof. Hill implies, there is a lurking danger that we may become in time a race of sanitary prigs in whom health is an obsession. But the need for popular knowledge of hygiene is real and urgent, and although much can be done—and is best done—by the general practitioner, there is scope for an immense amount of propaganda by societies, hospitals, and municipalities; criticism of their endeavours, where it is needed, ought to be constructive only.

Mr. Crew's book appears at a time when its subject is much in people's minds, and many will find it interesting to peruse. It may not be out of place to recall that on Oct. 12th these questions are to be considered by the St. Pancras branch of the British Medical Association, which will meet at 9 P.M. at the Association's house in Tavistock-square to hear an address by Sir Thomas Horder on the Aims and Methods of Health Education.

HYGIENE IN THE TROPICS.

WE have already reviewed the first part of Dr. Mary Blacklock's excellent primer [1] and welcome the appearance of the second ("An Elementary Course in Tropical Hygiene." Part II. John Bale, Sons and Danielsson. Pp. 108, 2*s.* 6*d.*). As Dr. Andrew Balfour remarks in his preface, the rules of health which it commends "are those which should be practised by all who live under tropical conditions, and more especially by native school-children," and "although intended in the first instance for schools in tropical Africa, this carefully written and painstaking work will be of service to all teachers who have to impart a knowledge of those important matters on which so much depends, and which, even at the present day, are so often neglected."

The second part, like the first, is written in clear and simple English, the information is well selected, and the illustrations good. It is written as a text-book for older children, students in training colleges, junior sanitary officials, nurses, and the like, but it forms an introduction to medicine, more especially as practised in the tropics, which would be interesting to many whose reading is merely desultory. Tropical medicine is a fascinating subject, and here it is well presented to the layman.

THE PRINT COLLECTOR'S QUARTERLY.

THIS useful periodical will be issued from 1927 onward in the months of January, April, July, and October, and will be on sale early in the month of publication at the price of 17*s.* 6*d.* per annum or 5*s.* per number. The magazine was founded in 1911 in America, but it was transferred to England in 1921 to the house of Messrs. J. M. Dent and Sons, Ltd. The illustrations and catalogues will be found very useful to collectors and all who are interested in prints and drawings, old or modern.

"CALCARDS."

ONE of the difficulties of working out a diabetic diet successfully has been the mathematical calculations involved, which have thrown too great a strain on the leisure of the average practitioner and on the ingenuity of the average patient. During recent months various simplified systems have been evolved, notably the "line ration" scheme and the "five grain" scheme, which have wonderfully eased the burden of constructing a suitable dietary. "Calcards" (David Challen, Ltd., 10, City-road, London, E.C. 2*s.* 9*d.*) forms another such system. A box is supplied containing upwards of 150 cards with vertical rulings, giving for each food substance taken the protein, the carbohydrate, the fat-content, and the total calorific value. By grouping a number of these slips together it is possible to select a varied number of meals which fulfil the requirements which have been prescribed, the only mathematical process involved being simple addition. The figures are given in decimals to two places, and are sufficiently accurate, and for the principal articles of diet weights up to 7 oz. are given.

To diabetic patients and to athletes in training and others interested in balanced rationing, "Calcards" should be of considerable assistance in arranging a reliable and varied menu.

The Harveian Oration

ENTITLED

BEFORE AND AFTER OPERATION.

Delivered before the Medical Society of London on Oct. 11th, 1926,

BY SIR BERKELEY MOYNIHAN, BART., K.C.M.G., C.B., F.R.C.S. ENG.,
PROFESSOR OF SURGERY, UNIVERSITY OF LEEDS.

THE distinguishing feature of the intellectual life of the last half century has been the progress of science. The advance has been revolutionary. New ideas are to-day expressed in so new a language, new conceptions and changed methods have created so new a vocabulary, that to the scientist of 50 years ago much of the literature of to-day would be unintelligible. In every department of scientific work the advance has, indeed, been stupendous, almost passing belief. Nor is the wonder of it lessened when we compare or contrast it with all that has happened in other departments of intellectual activity. In painting, in sculpture, in the design or the craft of architecture, in literature, we have altered our immediate interests perhaps, and have changed our tastes, but when we compare our efforts with the ideas and achievements of days gone by we remain, as we were, in a state of profound and reverent humility. In craftsmanship, as we have learned only in the last two or three years, perhaps nothing more exquisite has been wrought by men's hands than the finished perfection of the works which have been hidden for over 3000 years in the tomb of Tutankhamen.

ADVANCE IN SURGERY.

In applied science nothing so beneficent has ever occurred, nothing surely of greater advantage to humanity, than the progress of surgery in the days since Lister introduced his new methods. Of Lister, whose centenary we are shortly to celebrate, it may truthfully be said that no man has laboured so fruitfully in the material service of mankind. He has saved more lives than all the wars of all the ages have thrown away; he has lifted a heavy load of suffering and of sorrow from millions of hearts; his fame is imperishable. So great are the changes which he brought about that none can adequately appreciate them to-day.

The first result of Lister's work was the perfecting of the accepted methods of operation. Operations which had been of formidable danger became safe; recovery was not only more frequent and more rapid, but the severity of an operation and the suffering it entailed were so much diminished that the hindrances to its performance were no longer serious either to the patient or to the surgeon. The operations which had long been practised always with anxiety, and often with remorse, grew more frequent, and of unimagined safety. This led to a notable invention of new methods and their quick adaptation, perhaps after frequent change, to new experiences. Not only were new methods quickly discovered, modified, and steadily improved, but their appropriate application to the conditions disclosed during operation was by degrees fully established. At almost every step embittered controversies arose. The old quarrels as to priority in the invention or modification of methods and of new instruments seem now merely laughable, though at the moment so much was felt to depend upon them and to centre round them. Controversy is the life of scholarship, though, unhappily, acrimony and coarseness are apt to creep in and to soil the contestants.

Among the great adventures and the new enterprises which grew slowly out of improving methods were two which changed the face of surgery. These were, in the first place, the recognition and study of earlier stages in structural diseases than were ever before accessible, and secondly, the institution of plans to search for associated lesions beyond the immediate field of operation as soon as this latitude to the surgeon was made permissible by success. When in any abdominal operation the inspection of structural changes in the organ arraigned was made, conditions were at first disclosed of which neither the eye nor the hand of the surgeon had any experience, nor could the literature of medicine offer any help. Discrepancies were soon recognised between those pathological changes with which the long experiences of the post-mortem room and of the museum had made us familiar and those changes seen during operation. And when, unhappily, a patient died, a comparison of the description given by the operator with the conditions found on the autopsy table led to a considerable measure of disagreement. The surgeon was rebuked, not without contempt, for proclaiming the existence of conditions not discoverable to the same extent, or in the same degree, in the post-mortem room. And post-mortem experience was held to be infallible. It was to counteract this foolish view that I coined the phrase "pathology of the Living," and in exposition upon this text endeavoured to show that it was the condition of the parts during life which it was most essential for us to know if we were to help the living. Death not only changes the lineaments of a man's face, but so profoundly alters the parts affected by disease that the conditions before and after death may seem to be hardly comparable.

A study of the pathology of the living has led to a complete revision of our knowledge of abdominal diseases. Before the surgeon came our acquaintance with duodenal ulcer as a disease affecting multitudes of men and women hardly existed; a diagnosis of duodenal ulcer apart from its lethal complications had almost never been made. Of gastric ulcer, in respect of pathology, we knew much as a result of the work of Mathew Baillie, Cruveilhier, and Brinton, but the correlation between our pathological knowledge and our clinical acquaintance with the disease was woefully incomplete. The diagnosis of gastric ulcer was wrong in a very large proportion of cases as the surgeon was quick to discover. So with cholelithiasis. To read the first edition of Fagge's work on Medicine, one of the greatest books ever written and my sheer delight in student days, and to compare what he knew of cholelithiasis with what we know to-day, is to realise the immense gain to clinical medicine which has resulted from the work of the surgeon. Surgery, indeed, is the strongest of all research weapons in the hands of the physician, and posterity, I fear, will not hold us guiltless of the sin of allowing hostility, or imperfect understanding, to grow up between physician and surgeon in this great creative period in the science and the art of medicine. How much more rapid our progress would have been, how much more accurate our labours, what waste of time and effort would have been spared, if, instead of living each inside his own impenetrable ring fence, the physician and surgeon had met on common ground in the interest of the patient. Our only excuse, the only condonation, is that the sin was not so much of our own creation as hereditary.

VISCERAL INTERACTION.

A further most interesting feature of our extended operative work has been the disclosure of the interaction between the various viscera. We believe now that all gastric and duodenal ulcers are secondary affections; that their cause often lies in an infection elsewhere; and that this infection travelling by various paths may be revealed at the operation which is undertaken primarily for therapeutic purposes. So, too, with the origins of cholelithiasis, and with the causes of acute and chronic pancreatitis, and with their relationship to diseases of the appendix and gall-bladder. The interaction between the liver and the spleen is admirably illustrated by the effects of splenectomy. In cases of acholuric jaundice this operation has in the clearest manner settled for ever the old controversy as to the possibility of hæmolysis as a factor, a causative influence, in cases of icterus. When the spleen

is removed in Banti's disease, the terminal stage of splenic anæmia, the effects on the ascitic condition give the clearest proof as to the influence of the spleen upon the liver. The truths so learnt could be mastered in no other way than the way of surgery, by means of an operation which is not only curative, but is also a research method of the highest value. Surgical research demands infinite patience, great insight, dispassionate intellectual integrity, and sound judgment. A great generalisation of relevance not only in surgery but in medicine and in physiology may spring from all these. Experiments of immeasurably less value, of far less difficulty, involving no arduous responsibility, not demanding a sustained clinical observation, when performed upon animals in a laboratory are hailed as scientific achievements deserving and receiving the recognised reward which the Royal Society, a society founded to "improve knowledge," hastens to convey. But when man with his diseases, in all their baffling and manifold relationships, is submitted to inquiry the labour, judged by the standards of its reward, is unscientific! At least I am compelled to draw this lamentable conclusion when I see that no surgeon in active practice to-day is a Fellow of the Royal Society.

SURGERY AND ITS LIMITATIONS.

The mere craft of surgery is now hardly capable of great advancement. It is admittedly rash and dangerous to make such a statement with confident assurance, but I have no hesitation in so doing. If, for example, ulcers or malignant growths in the stomach are to be removed, is it possible to imagine that the mechanics or the artistry of the accomplished surgeon can be changed in any notable degree for the better? There is nothing in the craft of any art so exquisitely beautiful that it can surpass that shown by the skilful master of surgery. To watch such an artist is to realise that only infinite practice, the most solemn devotion to the details of craftsmanship, and a profound sense of spiritual dedication to a high purpose, are capable of creating and so ennobling the work of a man's hands. The results, too, of such labour by the most expert craftsmen, if they have not quite attained, are almost as near to finality and perfection as human effort can make them. This truth surely needs no illustration before such an audience as this. A word of comment and of warning is, however, necessary. Surgery is not learned easily. The training is arduous and protracted; indeed, it lasts a man's lifetime. It must begin under a master's eye and be influenced by his criticism, and not less by his spiritual encouragement. It must not be light-heartedly or recklessly undertaken, nor can it ever be a matter of display. In recent years, and especially, I think, since the war, the incompetent and ill-trained operator is allowed too free a hand and enjoys too wide a scope. The methods of surgery learned in the war do not fulfil the needs of civil life. The exigencies of war, the haste of war, and the sudden and heavy pressure of urgent work made it necessary to have many operators at once available. Their methods could not, and should not, be the same as those in the deliberate, full, and scrupulous ritual which alone is permissible in our more tranquil daily work. There is to-day too much bad surgery; surgery performed by those who have, perhaps, some natural skill which has never been trained and moulded to right practice. It is for the student of surgery

> "To act to-morrow what he learns to-day:
> Here work enough to watch
> The Master work and catch
> Hints of the proper craft, tricks of the tool's true play."

Our art at least must not be made tongue-tied by authority, but be given the freedom, vigour, and inspiration which come, perhaps insensibly, from contact with great masters. In surgical work craftsmanship is much and knowledge is much, and wisdom, which is the timely and rightful application of knowledge, is more, but as we establish our place in the world it is chiefly character that counts. Much of the inferior work now being done could not continue and would never have begun if the large hospitals to-day were doing their full duty to the public. There is need of more beds, of new departments, of more lavish equipment, but there is not sufficient money to supply our wants. Debts are heavy, overdrafts are many, waiting-lists are long. The public needs are great and urgent and should be met. We should regard the maintenance of the nation's health as worthy of the first demand upon the public purse and upon private beneficence.

IMPROVEMENT IN METHODS.

If, then, the mere technique of surgery has almost reached its limits, if no further great development of the power of our hands is possible, how is surgical work to advance? I believe that there is great room for improvement in two directions. We should seek to obtain an earlier access to our patients, and we should use far greater efforts than now seem general to improve the chances of the patient before operation and to help him after the operation is completed. Many patients come to us when their condition is so gravely affected either by the general advance of their disease, by its very nature, or by some sudden complication such as infection or hæmorrhage, that operation upon them cannot be contemplated without the deepest misgiving. Our first thought, and all our efforts must then be directed, not so much to the operation itself as to the resuscitation of the patient. By methods which are growing in number and in value he must be restored to a degree of health and of resistance which, so far as it is possible, will make the operation safe.

An earlier access to the patient is abundantly justified by the success of surgery. The aid of surgery must no longer be withheld until there is otherwise the prospect or the certainty of a loss of life. Relief from suffering is sometimes no less important than rescue from impending death. So many conditions are to-day allowed to drag their weary way along until the patient is suddenly confronted with a new and far graver peril, or is driven by the misery of suffering, when his health is squandered and spent, at last to seek relief. How is it that chronic duodenal and gastric ulcers are permitted to continue their destructive march until perforation occurs? At least nine out of ten of these perforations should be prevented. Why cannot the surgeon have the chance to help the sufferers from cholelithiasis in earlier stages of their disease? How is it that so very few cases of cancer are seen in an early condition? Every accessible cancer is at first curable. The statistics of the Leeds General Infirmary show this truth beyond dispute. Our cases of cancer of the breast are divided into three classes—

Class I., including cases in which there was no invasion of the axillary glands or of any other tissue than the breast, even at operation or after microscopic examination.

Class II., including cases in which there was invasion of the axillary glands but in which, apart from the skin over the tumour, there was no other part affected so far as could be ascertained.

Class III., including all other operable cases; cases of deep ulceration of the skin, &c.,

The percentage survival after three, five, and ten years is shown by the following figures, given by Miss Gretta Wardle, M.B.: —

	After three years.	After five years.	After ten years.
Class I.	88·2	87·5	77·7
„ II.	39·5	21·7	15·8
„ III.	25·9	3·45	0·0

More cases are operated upon now than formerly, but the increase, unhappily, is almost exclusively among Class III. cases. The efforts of the Yorkshire Cancer Campaign, however, are already resulting in opportunities for operation in earlier stages of the disease, and there appears to be a clear obligation upon our profession now to give such general instruction to the public as will make them realise the importance of seeking medical advice for conditions which they have too long regarded as trivial, or have ignored. A campaign of public education in matters

of health is long overdue. If it is frankly and fearlessly undertaken we shall enlist public understanding and sympathy with the work of our profession, and we shall never again witness the lamentable exhibition of bitter prejudice against our attitude and ideals which recently spread throughout the country. Prejudice is the emotional reaction of ignorance to truth. Let us dispel ignorance. Our case is surely unanswerable.

Before any surgical operation is undertaken we must, in the first place, be sure that mechanical treatment rather than medicinal or any other form of medical treatment is necessary or preferable by reason of its greater expedition or greater safety. In the second place, we must ensure that the patient is in the best physical and mental condition to undergo operation. In the third place, we must pay great regard to the exact appropriateness of the procedure employed to the conditions disclosed. And finally, we must not be content to believe that our interest in the patient ceases if he survives the operation, or on the day when his wound has soundly healed.

When contrasted with medical treatment, an operation is often considered as the method by which a new risk to the patient is being added, and little thought, if any, is given to the far greater risk from which the patient is, perhaps, being rescued. If a patient chances to be the victim of a disease which causes a good deal of discomfort, even it may be a formidable degree of temporary suffering, yet does not on the whole greatly impair the general or physical efficiency, and does not appear to be a grave menace to life, it may well seem that an element of danger is being introduced when an operation is mentioned. We have, however, to recognise that the safety of surgery has become so assured that its methods may be employed, and are daily employed, not only for the rescue of a threatened life, but for the relief of recurring pains, discomforts, or any other forms of physical disability. But there is something far more important than this, something which requires the most positive statement, and it is this: that surgical treatment for many diseases is not only more effective than medical treatment, it is far safer. In my little book on Gastric and Duodenal Ulcer I review ten years' work in the operation theatre, and I discuss the material available from the post-mortem room over the same period of time. The irresistible conclusion must be drawn that by comparison with surgical treatment in competent hands medical treatment is so dangerous in the chronic form of these diseases that fresh and far sounder arguments for its continuance, or for any reliance to be placed upon its permanent effects and value, must now be brought forward. Medical treatment having been faithfully tried in one or two attacks of gastric and duodenal ulcer, and having failed, a repetition of the treatment will be followed by a higher mortality than is now associated with surgical treatment in skilful hands, and the chance of permanent relief is not to be compared with that which surgery affords. And the same arguments hold good with regard to cholelithiasis. The deaths that follow upon surgical treatment are deaths resulting from operations necessarily extensive because of the advanced state of the disease, which must too often be performed upon patients suffering from jaundice, hepatic insufficiency, acidosis, carcinoma, chronic pancreatitis, or some other preventable complications. The early recognition of these diseases should be the quest of the physician. In those stages they may be amenable either to prevention or to relief. In the stage when we see them to-day there is no skill even of the most practised physician which can do more than render the diseases somnolent, not only ready to awake and create afresh the old disturbance at any moment, but in their slumber to cause changes which hasten a patient to the grave. If the physician instead of a too tenacious hold upon the declared case of cholelithiasis, for example, would seek out the symptoms and the signs of the earliest phases of the disease, its antecedents, or its causes, and so enable us to counteract its origins and to check its development, we should all be happier. Our hospital system, with its most inadequate supply of beds, unfortunately restricts the activities of the physician to the patients whose diseases are advanced. The forward-looking minds in medicine are attracted by the prospects of preventive medicine.

Surgical treatment, in many abdominal conditions, may therefore often truly claim to be speedier and safer than medical treatment, and to be able to restore the patient to a brighter degree of health and to a greater freedom for enjoyment. But it must be competent and careful surgical treatment, carried out by those who have trained themselves to secure the best results.

In the future we must, I think, look for advance in surgery not so much to improved methods of operative technique, as to a wiser application of methods now almost perfected. It is therefore our task to improve surgical judgment, and to that end a long survey of past experience is essential. And it is most necessary for us to devote a greater measure of attention to the preparation and after-care of the patient. Surgery has been made safe for the patient; we must now make the patient safe for surgery.

BLOOD TRANSFUSION.

The procedures by which we lessen the risks of operation are already increasing in number and in efficiency. Among the most valuable I would place the direct transfusion of blood. For my early knowledge on this subject I am greatly indebted to Crile. In the spring of 1908 I paid a visit to him in Cleveland for the express purpose of learning something of his technique, and brought back with me the instruments he then used to anastomose the radial artery of the donor to a vein of the recipient. The method was difficult, and had the disadvantage that we had to judge of the amount of blood given by observing the effect on the receiver or upon the donor, or by measuring the time during which blood flowed between them. The results, nevertheless, were good. From that year onwards I have transfused blood in all needful cases, and there can be no doubt that many lives have been saved thereby, and in many more cases convalescence has been hastened.

Transfusion is used when severe hæmorrhage has recently occurred, as in cases of ulcer of the stomach or duodenum, in splenic anæmia, in fibroid tumours of the uterus, or when carcinoma is present; in cases of anæmia associated with growths in the stomach or colon; in cases of general enfeeblement when the red cells are fewer than 4,000,000. It is also used not infrequently in cases of inoperable malignant disease when deep X ray therapy is being applied, since a considerable reduction in the number of red cells is sometimes found to follow exposure to these powerful rays. As a rule only one transfusion is necessary, but I have on a few occasions given as many as five transfusions. For example, in a very severe case of splenic anæmia which I saw with Dr. G. W. Watson the red cell count was 900,000, the abdomen was full of fluid, and the liver enlarged. Five transfusions of blood brought the count up to 4,300,000; the abdomen was twice tapped and about 30 pints of fluid removed. I performed splenectomy. Convalescence was easy and assured; health and strength were regained, and no fluid has since accumulated within the abdomen. Transfusion may be employed, too, both before and after operation. On many occasions after the operation of gastrectomy, especially for carcinoma or for jejunal ulcer, the transfusion of 15 ounces of blood a few days after operation seems to alter the whole prospect of the case. The patient feels better at once, is more hopeful as to his recovery, and inclines to food for which he may before have felt distaste.

The transfusion of blood has many virtues: the red blood cells seem to act as well in their new surroundings as in the old; they last a sufficient length of time to tide the patient over a crisis; they appear to encourage and, indeed, to cause the red marrow of the recipient to produce red cells more rapidly and

in greater number than before; the fluid remains in the vessels far longer than is the case when saline solution alone is infused; and finally, conditions such as the mobilisation of cholesterol, which may be of incomparable assistance in the fight against infections, are at once established.

POST-OPERATIVE PROCEDURE.

Too much has been done by catharsis and starvation to reduce the condition of patients before operation. I encourage patients to drink as much fluid as possible for a day or two before operation, and of all fluids a 5 per cent. solution of glucose appears to be the best for this purpose. And I suppress the philocathartic propensities of nurses. An evacuation of the intestine the evening before an operation is all that is necessary if the patient has been accustomed to a daily action. If constipation has been the habit it is, perhaps, a mistake to change it, or to endeavour to do so, in the last few hours before operation. I am sure that patients suffer far more from flatulence if they have been purged. And the deprivation of fluids after the ardent administration of pills and draughts and enemas is a grave disadvantage to all patients. It is a mistake to begin an attack on the patient by the same ritual immediately after operation upon any of the abdominal viscera. They have been subjected to a rude invasion and are no doubt feeling the affront. Why not leave them alone for 24 or 36 hours at least until their self-respect is recovered? There is too much meddlesome interference in these matters, both before and after operation, and a great deal of quite needless discomfort is added to the patient's ordeal. There is in the great majority of cases no difficulty in compelling the intestine to act, whenever this is desired, by aperients, enemata, the administration of eserine, or even of pituitrin if there has been intestinal obstruction. The stretching of the anal sphincter after the operation of colectomy, or the introduction of a short tube within the rectum in other cases is often a help in allowing the unimpeded escape of gas.

BLOOD EXAMINATIONS IN SURGICAL WORK: ACIDOSIS.

We are quickly learning the great advantage of blood examinations in surgical work, and we are realising how closely the clinical condition of a patient corresponds with and is explained by the chemical state of the blood. One of the most serious post-operative conditions, formerly almost invariably fatal, is acidosis. It may occur as a sequence to operation upon a dehydrated and starved patient, upon patients who have jaundice or hepatic insufficiency, or whose kidneys work inadequately; or it may occur as a direct consequence of the anæsthetic, especially if chloroform is used. It is some years since chloroform has been given to any patient of mine; it is far too dangerous a drug, and over its late effects, often unrecognised but none the less serious, we have had little or no control until recently.

Acidosis was formerly one of the most dreaded of post-operative complications; now, happily, by foresight and by after-care the risks of it are greatly diminished. The reaction of the blood is always faintly alkaline, and even in extreme degrees of acidosis shows little change; it never, of course, becomes acid. When in the body fixed acids, oxybutyric acid, and diacetic acid are produced they are at once combined with the sodium bicarbonate of the blood as a result of the "tampon action" of Bayliss, and carbonic acid is produced. The respiratory centre being extremely sensitive to this acid is stimulated, respirations are increased, and the pulmonary ventilation throws off the acid until the original relationship of bicarbonate of soda and carbonic acid is restored. In this reaction bicarbonate of soda has been used up, and there is consequently a diminution of the alkali reserve, and there results that "modification of the normal equilibrium between acids and bases whereby the power to neutralise acids is diminished," that is acidosis. There are other buffer substances in addition to bicarbonate of soda; the blood cells may lose their potassium and sodium to the plasma and so help to keep the balance between acids and bases. So far as elimination is concerned the power possessed by the kidneys to excrete acid salts and to leave behind a part of the base with which the acids are in combination is one of high value. By the intestinal canal phosphoric acid is excreted. The loss of equilibrium between acids and bases may clearly be due, not only to increased production of acids which engage a larger quantity of bases, but also to a primary deficiency in the alkali reserve, or even to a combination of these two conditions, hyperacidity and hypo-alkalosis. The acids produced in excess are intermediate products in imperfect fat katabolism. The incineration of fats is set alight by carbohydrates, and a deficiency in carbohydrates is therefore the main causative influence in acidosis; accordingly the indication is to supply more carbohydrates.

The carbohydrate upon which we rely in cases of acidosis is glucose. It is, however, not seldom difficult to administer it, for vomiting is often so constant that none can be given by the mouth; little is absorbed when introduced subcutaneously; and none in sufficient amount, or with sufficient rapidity is absorbed from the rectum in a patient greatly enfeebled. Happily, the intravenous method of administration has proved to be extremely satisfactory. We now adopt the method suggested by Matas of giving a 5 per cent. or 10 per cent. solution of glucose, with or without bicarbonate of soda, continuously, an apparatus being used which maintains a constant temperature. And the glucose is utilised by administering insulin at the same time either intravenously with the glucose or hypodermically under very careful restrictions. Though this method has only been used by us for the last two years it has already proved its high value, and beyond question has saved lives.

The necessity for the control or the prevention of acidosis is at its highest in cases of diabetes. The risks of operation were formerly very high and not infrequently any surgical measures considered desirable were either reduced to the very smallest degree or were postponed or even denied to the patient. In cases of cholelithiasis, for example, I have for this sole reason often known a necessary operation withheld because of the fear of death or of imperfect and protracted healing of the wound. To-day I regard the co-existence of glycosuria and cholelithiasis as a still more urgent call for operation. And there is no longer any doubt that, with care before and after operation, with regular blood examinations as a part of the routine, the risks of surgical treatment are no greater in these cases than in others. It is important to recognise the value of a supply of utilisable sugar in diabetes, and possibly the administration of carbohydrates before operation, together with insulin in quantities sufficient to ensure their assimilation may sometimes be necessary. Fluid must be given generously and catharsis and starvation both avoided. Glucose intravenously and insulin subcutaneously in the proportion of 2 g. of the former to 1 unit of the latter must be given to the extent deemed necessary, a constant watch being kept on the urine for sugar and diacetic acid. The importance of avoiding any infection during or after operations upon diabetic patients, because of its effect in hastening, or even causing, coma is probably familiar to many surgeons. In such cases insulin appears to have less value than usual. The necessity for dealing actively with infections in those who suffer from diabetes is not less important.

ALKALOSIS.

The opposite condition, alkalosis, is sometimes, though more rarely, a source of anxiety after operation.

Alkalosis is also a result of a change in the ratio of free carbonic acid concentration to bicarbonate of soda concentration. The free acid may be reduced either by increased pulmonary ventilation, or by augmentation of the combining power of the blood plasma with carbonic acid. In either case alkali reserve in the blood is increased, and there is a consequent tendency of the blood to veer more strongly towards the alkaline side. Expressed by Henderson's formula, the blood reaction at any moment depends upon the balance—

$$\frac{\text{Free } CO_2 \text{ concentration}}{NaHCO_3 \text{ concentration.}}$$

An increase in the numerator or a decrease in the denominator indicates acidosis; a decrease in the numerator or an increase in the denominator indicates alkalosis. A change in both numerator and denominator in the same case may at times be observed. Any change in the numerator excites an attempt on the part of the body to compensate by causing

an equal change in the denominator and vice versa. In alkalosis resulting, for example, from a greatly lowered CO_2 content of the blood the compensatory effort takes the form of an increased excretion of alkali and a consequent lowering of the bicarbonate of soda in the blood plasma. If, on examining the blood, this lowered plasma bicarbonate is found, the tendency is to assume that it is due to acidosis. There is, consequently, a danger of confusing the two opposite conditions. They can, however, be distinguished after an examination of the urine. In acidosis there is an increased excretion of ammonia, produced in order to economise the "fixed" alkalis of the blood, whereas in alkalosis the chief need being the riddance of these attacks, ammonia production is no longer required, and is, therefore, reduced to the smallest degree. The two conditions, acidosis and alkalosis, are alike, too, in this—that acetone bodies may be present in the urine in either condition. In acidosis they are in part at least the cause of the condition; in alkalosis they are produced as a part of the compensatory mechanism which seeks to neutralise the excess of alkali.

Alkalosis, then, may result either from an excess of alkali or from a decrease in CO_2. The clinical conditions in which it may occur are:—

1. *Excessive Overdosage with Alkalis.*—The danger of this is small, except, perhaps, in cases in which the renal functions are impaired. Venables reports [1] seven cases of alkalosis following the alkaline treatment of duodenal ulcer. One patient, a male aged 50, who had suffered for a few months from excessive vomiting, died comatose. He became very depressed, complained of severe headache, of intolerable itching of the skin, and of complete anorexia; he suffered a recurrence of vomiting, and was extremely irritable. The blood-urea was almost quadrupled [was this a case of uræmia?]. Hardt and Rivers[2] relate a similar series of cases of toxicity. Alkalosis has resulted from the administration of sodium bicarbonate in cases of acidosis, especially when associated with poor renal function.[3]

2. *In Certain Gastric Disorders where Free HCl is Diminished.*—For example, in cases of duodenal or gastric obstruction, either accompanied by copious vomiting or controlled by frequent lavage of the stomach, both involving a constant loss of acid. The condition has been produced experimentally by McCann.[4]

3. *In Hyperpnœa due to Increased Pulmonary Ventilation with Excessive Loss of CO_2.*—Alkalosis is accordingly found when there is a want of oxygen, as in those living at high altitudes and in carbon monoxide poisoning. It may follow prolonged immersion in hot water, in consequence of the hyperpnœa induced to keep down the body temperature, and it may be present in cases of high fever. In alkalosis the rise in the carbon dioxide combining power of the blood may increase from a normal of about 60 per cent. to 120 per cent. or even more, and there is a diminution in the chlorides to nearly one-half of the normal. The blood-urea is raised.

I have only a slight experience with this condition, but I have no doubt that it has been overlooked in my earliest experience, and I should have remained unfamiliar with it but for my colleague Dr. MacAdam. The difficulty in its recognition is largely due to the resemblance which the symptoms caused by it may bear to those present in acidosis. It is to be feared in those cases where vomiting has been a long-continued and distressing feature before operation. The chief symptom is vomiting, which is both copious and frequent. The stomach may be emptied of a large quantity of fluid and yet fill again very quickly, for within an hour or two severe and prostrating vomiting may begin afresh; headache, generally occipital, is severe and often throbbing in character, and intense dizziness occurs on the slightest movement of the head; there is much pain in the back. Numbness of the extremities appears early with facial ridigity. This is quickly followed by tetany with the characteristic spasm of feet and hands. In the severer cases general convulsions may appear. There is increased electrical excitability and Chvostek's and Trousseau's signs are both present. The patient after a period of irritability will drift into a comatose condition unless the cause of the symptoms is recognised.

The *treatment* consists in supplying fluid by the rectum and subcutaneously, and by the intravenous injection of saline solution in quantities of from one to two pints twice at least during the 24 hours. There is a good deal of experience to show that a saline infusion produces only a temporary effect, an effect which rarely lasts for more than six to eight hours, and a repetition of the administration is therefore necessary and is to be preferred to the injection of a larger quantity on a single occasion. A very dilute solution of hydrochloric acid, one teaspoonful to 10 ounces of water, may be given as a beverage, but the frequency of the vomiting in the acute phase of the condition makes this of little value. With a Jutte tube in the stomach the fluid has a better chance of absorption and may for a time be given in larger quantities; the excess will escape by the tube.

CHOLELITHIASIS.

Evidence as to the high value of blood examination is found also in cases of cholelithiasis and of genito-urinary diseases. The work of Dr. Cecilia Shiskin and of Mr. G. Collinson upon my cases of cholelithiasis has shown that a knowledge of the cholesterol content is helpful in diagnosis. The work of Dr. MacAdam and Dr. Shiskin [5] upon the cholesterol content of the blood in genito-urinary sepsis has shown how significant a low value may be in demonstrating the need for the rehabilitation of the patient before an operation is undertaken. In such cases the determination of the blood-urea is also of great importance. It is not an extravagant claim to make for these methods that in many cases, perhaps even in a majority, they may prove a more reliable guide than the clinical sense of the surgeon. In the series of 80 cases examined by MacAdam and Shiskin there were 18 with hypocholesterolæmia, and of these 16 died of pyelonephritis; in only one-half of these cases "did the clinical opinion of the general condition of the patient contra-indicate operation." A low cholesterol content and a large excess of blood-urea indicate the need for delay in operating and for the wise employment of all methods in repairing the damaged health of the patient. Among these methods are continuous slow drainage of the distended bladder in cases of enlarged prostate, a dietary generous in carbohydrates, and the intravenous administration twice, or even thrice, daily of normal saline solution in quantities of one pint on each occasion. The direct transfusion of blood finds useful application here also.

I have realised the possibility of augmenting the cholesterol content of the blood by transfusion; the increase is found to be out of all proportion to the cholesterol content of the transfused blood, and it would seem that there is a quick and lasting mobilisation of cholesterol from the storage deposits in the body of the recipient. This hypercholesterolæmia indicates very probably a strengthened defence against infection. Perhaps no operation in surgery shows so striking a difference between procedures of haste, and of judiciously used delay, as the operation of suprapubic prostatectomy.

POST-OPERATIVE RESULTS IN JAUNDICE.

One of the most satisfactory results of the careful preparation of patients before operation has been seen in those who were jaundiced. Formerly such patients were not seldom denied the relief of surgery because of the grave risks attached to it, and no less an authority than J. B. Murphy advised against operation in cases of carcinoma of the head of the pancreas. One of the disasters which occurred after operation was unceasing leakage of blood from many vessels. On post-mortem examinations large masses of blood were found in the peritoneal cavity, in the subperitoneal tissues, in and around the wound, after

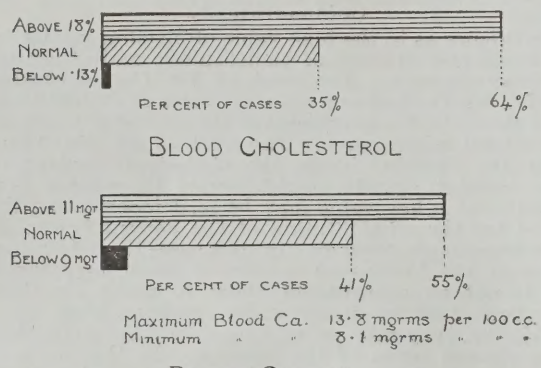
[5] Brit. Jour. of Surgery, 1925, xii., 425.

a great deal had been already lost in the dressings. An examination of the blood showed a delayed coagulation time. After a visit to Kroneker's laboratory in Berne I began the administration of an alien serum to all jaundiced patients; antidiphtheritic serum was first tried when needed in haste; afterwards freshly prepared rabbit's serum given in doses of 20 c.cm. twice or thrice repeated. Blood examination before and after showed a reduction in the coagulation time. It is supposed that the prolonged coagulation time in jaundice may be in part due to a reduction in the amount of calcium in the blood. To reduce this period the administration of calcium chloride by the mouth was first suggested by Almroth Wright, but my experience seemed to show that little or no good came from it. An examination of the blood in a series of 55 consecutive cases of cholelithiasis has shown that the calcium content is often high. If the normal is assessed at 9 to 11 mg. in 100 c.cm. of blood, 30 patients were found to have a calcium content of over 11 mg., 22 had a normal content, and 3 had a content below 9 mg.; four of the patients



Examination of the blood in cases of cholelithiasis to show the cholesterin and the calcium contents.

were jaundiced; their blood calcium was 9·2, 8·6, 8·6, and 8·1 respectively. If a diagram is made showing the cholesterol content of the blood in cholelithiasis it is found nearly to correspond with a similar diagram showing the calcium content; hypercalcæmia and hypercholesterolæmia almost coincide. To increase the calcium content is not easy. A very slight and a very transient effect is produced by the oral administration of a calcium salt; a very definite and not so transient an effect is produced when 5 c.cm. of a 10 per cent. solution of calcium lactate is introduced into the veins; being in crystalloid form the calcium is quickly excreted by the liver cells and escapes into the bile. To counteract the quickly passing stage of calcium increase a repetition of the dose on three or four consecutive days, before and after operation, reduces the coagulation time when this is most needed. (My chemical assistant, Mr. G. Collinson, is responsible for the estimations and for the diagram.)

In jaundiced patients, or in patients in whom there is hepatic insufficiency (the tests for which are not very satisfactory), a direct transfusion of blood, the intravenous administration of glucose, with or without a little carbonate of soda, on two or three occasions, or continuously, a very generous carbohydrate diet, and an abundance of fluid by the mouth, all help to lessen the dangers of operation. In such cases chloroform should never be given, and as little ether used as possible. Local anæsthesia with gas and oxygen will often suffice; the surgeon, remembering that it is not his comfort during the operation but the patient's safety that counts, does not ask for a complete relaxation of abdominal muscles.

Vomiting is sometimes a distressing and a dangerous symptom after operation. It may be due to many causes, adynamic or obstructive; it may be the warning symptom of acidosis; it may occur in cases of urgent surgery for acute peritonitis. The moment that it appears to be anything more than the result of the anæsthetic the stomach-tube should be made ready. Early evacuation of the stomach with a little lavage may check the further development; the discomfort caused is amply compensated by the relief which soon follows. If vomiting is frequent, small amounts only being ejected, it is certain that the stomach is overloaded; the tube may evacuate two or three pints of dark fluid. There are times when it is necessary to wash the stomach repeatedly. In such cases I have found great advantage from the Jutte tube passed through the nose. The tube is very small, weighted at the end; it is easily slipped down the nostril and then swallowed. It may lie in the stomach for days, and the evacuation of fluid may be hastened by the application of a syringe to the other end. One great advantage of it is that the patient may drink copiously while the tube lies in the stomach. This is a very great relief to the patient, and the excess of fluid trickles away by the tube. As Matas has shown, in cases of high fever, iced water given generously causes the stomach to act as an icebag conveniently placed beneath the heart and over the aorta and vena cava. I have found the greatest help from this tube on several occasions.

CONCLUSION.

My thesis, then, to-day is one with which all will agree: it is that surgery is not only a question of operating. The surgeon in the last generation has had immense and unprecedented opportunity for research. Of these he has not failed to avail himself. He has not only brought relief to countless numbers of patients, but his investigations have created new knowledge, and have corrected old knowledge, as to the causes and conditions of disease. He has become very expert as a craftsman. But more than craftsmanship is needed. It is now his duty to concern himself with all relevant inquiries as to the condition of his patient before operation, to change those conditions to his patient's advantage, and to control his patient after operation, in order that the safety and the permanent success of his operation may be ensured. I foresee, therefore, a change, not only in the aspirations and in the labour of the surgeon, but in the methods by which he is trained for his task. In my day far too much time was spent in anatomy, and a needlessly intricate knowledge of some of its branches was required of us. The years of training might now be profitably spent in learning more of physiology, biochemistry, pathology, and in saturating the surgeon in his plastic years with the faith and the practice of the religion of research. The science of surgery in days to come will be advanced by men trained in the methods and imbued with the spirit of experimental research, though it will no doubt continue to be practised to their profit by those who are merely craftsmen. The surgeon is not simply the tool of other minds; he is not merely required to carry out the mechanical and routine details of a procedure the necessity for which, and the plan of which, others have decided. A life is entrusted to his hands. It is for him to safeguard it. It is he who must finally decide when surgical treatment is needed, and what shall be its scope and application. It is he who must take pains so to prepare or to rehabilitate his patient that the anxieties, the discomforts, and the perils shall fall as lightly as possible upon one who at the moment is perhaps less than ever able to bear them. The surgeon may in some degree share his responsibilities with others, but the chief responsibility must always lie with him, and being his must be exercised not only during the operation but also before, perhaps long before, and also after, perhaps long after, the operation is performed. The operation itself is but one incident, no doubt the most dramatic, yet still only one in the long series of events which must stretch between illness and recovery. The patient, passing through the deep waters, may find them chill and bitter, but the thought of our labour in his service, when the toilsome days are ended, will lie as a glowing coal at his heart.

An Address

ON THE AIMS AND METHODS OF HEALTH EDUCATION.

Delivered before the St. Pancras Division of the British Medical Association on Oct. 12th

BY SIR THOMAS HORDER, BART., K.C.V.O., M.D., F.R.C.P. LOND.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

[AFTER a few preliminary remarks in which he pointed out that he was speaking as a private individual and not as the champion or mouthpiece of any society or association, Sir Thomas Horder continued:—]

Let me first of all dispose briefly of certain aspects of health education with which I shall not be much concerned, partly because they lie outside the actual controversy which has arisen in connexion with the subject and partly because they are being already dealt with more or less satisfactorily. There are three of these, and they seem at least to rest upon sound bases, capable of uninterrupted expansion. Public health education is one of them, industrial health propaganda is another, and I shall assume that instruction of the citizen when he is sick, as how best he can prevent himself becoming sick again, is provided for by the doctor who attends him. Even if this last assumption be too large the opportunity and the medium for health knowledge are forthcoming as the result of personal contact of patient and doctor, so that if there be the will to keep healthy on the part of the patient, and some desire to be helpful on the part of the doctor, all should go well.

There is, of course, a good deal of overlapping of public health and industrial health education on the one hand and personal hygiene instructions on the other. Inasmuch as the best part of public health is preventive medicine, as Sir George Newman so constantly reminds us, the Ministry of Health and its army of medical officers of health are, by their educational propaganda, doing a great deal for the personal hygiene of the individual citizen. Reciprocally, and here again Sir George Newman has, in his recent oration before the Hunterian Society, and in his own illuminating way, pointed this moral—the practitioner and the patient form a field of investigation and experience which, properly used, bring valuable material to the study of public health. Education in industrial medicine is a new departure, perhaps a little overdue, but full of great promise. This, too, must inevitably make a large and valuable contribution to individual health. By adding the stimulus of slight coercion many people may be induced to overcome the indifference which they manifest on the subject of health so long as they seem to be healthy. If preference and advancement go, other things being equal, to those employees whose health reports are best as the result of following the advice of the doctor acting on the firm's behalf, thus avoiding illness, this will act as a strong inducement to attend to the instruction given.

My chief concern in this address is not with these three aspects of health education so much as with health education as it affects the individual citizen in a state of relative health and efficiency. Is it desirable that we should give him information on health matters; if so, what sort of information should we give him, who should be responsible for it, and through what medium should it be given?

1. IS INFORMATION ON HEALTH MATTERS DESIRABLE?

There seems to be a general consensus of opinion that it is desirable. Even if some folk are inclined to doubt the value to the public of any instruction on matters of personal hygiene, the public has decided that it wants health talk and means to get it. How much it wants instruction is doubtful; that it wants the health "story" is certain. We must distinguish between the "story," information, and instruction; I think the demand is roughly in that order. Judging by the number of health articles and the frequency of discussions on health topics in the newspapers, there seems to be a veritable lust for news of this kind. The reader wants to hear about his lungs and his liver, about the diseases that he has himself had, or that his friends have, and still more about the diseases that he fears to get. There is no difference between popular subjects of conversation and subjects dealt with in the popular newspapers, and what subjects are more popular in conversation than health and disease? The man in the street likes to read about the latest cure for cancer, even though he has read of others, equally revolutionary, only a week ago. He loves to hear about the cure for tuberculosis which the profession, through ignorance or jealousy, refuses to use, and stop consumption once and for all. And how, from lack of funds and encouragement, the discoverer of the cure languishes in obscurity in a foreign land, surrounded by a few faithful followers whose enthusiastic support is wholly disinterested, yet entirely ineffective. He also likes to know about doctors and the queer ways they have, which his paper tells him are called "medical etiquette"; about their differences; about the disgraceful manner in which they ostracise the unqualified man who is so much more clever than they are that they won't allow him to get qualified, much as he wants to, so that he may place his great gifts at the service of the public. He will want to know what happens at this meeting, and will read with interest any references to myself as one of the die-hards or reactionaries of the profession. I don't think we ought to grudge him any of these things, since the intelligent reader is fully aware that the view taken is determined by the policy of the paper at the time of publication, there is no harm done. Even editorial grievances against the profession in general or against its official bodies in particular should not be objected to.

2. WHAT INFORMATION IS DESIRABLE?

When we turn from gossip and scandal to information—genuine news—I think we ought to take a large view of our opportunities, nay, I will say of our duties, remembering that we must succeed in getting the public interested, and in getting it to realise that health is its affair much more than it is the doctor's affair, before we can hope to arouse its attention to specific instructions. In these matters the public has grown up a good deal and is able to understand much about science and its applications. I would encourage the giving of information on all things connected with health and disease. Such information might include the history of medicine; the meaning of research, with illustrations of the patience, training, and persistence required by those engaged in it; how discoveries come, slowly and painfully; the value of comparative pathology and therapeutics in animals and in plants; and, from time to time, précis of definite and established advances and their bearing upon practice.

So much for gossip and information. What ought we to offer the public by way of instruction upon how to be fit and keep fit? This matter seems simple enough to some, but I must confess it seems very difficult to me. That may be because I am not an apostle of any doctrine that I have an itch to preach, and because I know from experience that health is an adjustment of so many factors, having quite different values in different individuals, that it seems to me entirely unlikely that particular prescriptions can ever be universally useful. I therefore think that maxims drawn up for guidance in personal hygiene should be few and brief, embodying general principles and avoiding particulars. How can they deal in particulars with any hope of success since they go to all and sundry, to the young and to the old, to the fat and to the lean, to the blonde and to the brunette, to the tall and to the short, to the phlegmatic and to the sanguine, to the asthenic and to the sthenic? If I tell everybody to eat bran and raw vegetables what of the people with flatulent colons? If I say that it is good for all persons to

secure at least two actions of the bowels daily, what of the many people who are always at their best when, as judged by this standard, they are a little constipated?

A fallacy underlying much personal health instruction is that the ideas upon which the maxims are based are born of the advice given with success to ill persons. What is found to be good treatment for the patient, or for the person who is discovered to have some morbid tendency, is assumed to be good for those who are well.

I do not think instructions to the public on health matters should aim at embodying the latest theories in pathology or in therapeutics. Rather do I think that such instruction should always be kept high and dry from theories, however attractive. This requires an exercise of forbearance not possible with all of us, a reflection which leads me naturally to my next question.

3. WHO SHALL BE RESPONSIBLE FOR THE INFORMATION?

For the gossip and the "story," as already said, we have, as doctor, no reponsibility. That rests with the editor and the proprietor of the journal publishing them. For the news I suggest that the medical journalist and "our medical correspondent" who is, of course, chosen *because* he is a journalist, are the best persons to do the writing. But I think the interest of the public is best served by all such articles and paragraphs, and books also, being controlled by experts whenever they deal with actual diseases and their treatments. This would test the bona fides of those newspapers which claim that they are really desirous of giving their readers reliable information. The experts at the Ministry of Health would, I am sure, be willing to "vet" such articles. But the public is chary of Government departments and officials in things like these. The Federation of Medical and Allied Services already does something of the kind through its panel of experts. It should not be difficult to arrange some even more representative body the names of whose personnel might be published from time to time—but not too often!—so as to assure the public that it was a competent body for the purpose in hand. Laymen should, I think, sit on this committee. I favour the presence of laymen on all councils and committees that have to do with health questions and the public. I have had too much experience of their great help in this capacity to have the least doubt on the point.

When we come to actual matters of health instruction—the preparation of these maxims, for example, that I spoke of—I am quite sure that control by some responsible body is essential to the public interest. The laymen would naturally leave these technical points to their medical colleagues. I say naturally because it is surely a glaring anomaly that a layman should write articles and books on technical medical subjects under the ægis of a doctor or a mixed health committee. This seems to me to be identical with the offence known as "covering," an evil that we fondly supposed was dead.

The work of a body such as I have suggested would prevent glaring discrepancies in health instruction. I have had sent to me what I regard as some very excellent pamphlets on health instruction, and some that I regard as not so excellent. Many of them would, in my estimation, improve greatly by a little editing and, as I suggested earlier, by the elimination of non-essentials. The writers' craving for being "up to date" lowers the value of several. Here, for example, is one on "Cancer," with a footnote referring to the "first results" of certain researches which were announced "whilst the leaflet is in the press." Who writes these leaflets? In the great majority of cases we are not told; no doubt this omission is due, in most instances, to a desire to conform to the tradition about avoiding publicity. In others it is probably due to the fact that the writer is not a qualified practitioner and modestly suppresses the fact. But would not the value of this form of propaganda be increased if the public knew that the leaflets had passed through some sort of clearing house, and this fact were attested? Since these leaflets are increasing very rapidly the point is not without importance.

The individual medical man can never, so it seems to me, be a safe teacher of health maxims to the public. Nor should he take upon himself this great responsibility. Which of us, after all, is quite free from obsessions? And whose obsession lasts out even a generation? Be as watchful about this as we may, if we really have the public interest at heart we ought not to risk stamping the mark of our particular bent of mind and training and experience upon a matter so vital as this. And this danger is not necessarily avoided if we work through, or with, a committee, unless we are very catholic in the choice of our colleagues. We ought to be careful that we do not choose those who merely reflect our own ideas, or the trouble will be multiplied. So much is this the case that it is quite easy to forecast what health maxims will emanate from any committee if we know that they have come together because they hold the same views. These views must necessarily activate all their work. I do not propose to criticise any particular health society, not even the latest addition to these useful bodies. It should be quite apparent to all of us who follow such movements that the policy of this new body is not yet settled. This is unfortunate, because in the process of finding a policy the public may suffer. I do not think this same society has yet decided if it is in the public interest that inspired laymen should write technical articles under cover of their medical colleagues. And the relation that it bears to existing official bodies has not yet been defined—to the General Medical Council, for example. In April last the President of the society stated, I am told, that "the relation of the society to the General Medical Council is one of acute antagonism." A week ago we were told, I believe, that "the society has never come into conflict with the General Medical Council, with whose functions it is in the closest sympathy, and for which it has the greatest reverence and respect." Until this body has found its bearings I was content to make such criticisms as I had to the President privately. But my name has unfortunately been coupled with that of a critic whose strictures it has, perhaps not unreasonably, resented, and, further, I have been accused of participating in "stage management" in connexion with this meeting. It looks as though the society anticipated that I should criticise it and desired to "get a blow in first." Perhaps I ought to accept this sign of nervousness as a delicate compliment. However, I have received very generous apologies from the President and from both the secretaries of the society; but as the error was committed publicly I take this opportunity of issuing a disclaimer.

I now turn to my fourth question.

4. THROUGH WHAT CHANNELS AND BY WHAT METHODS SHALL HEALTH EDUCATION BE GIVEN?

In reply I would say first of all that the channels can be neither too numerous nor too powerful, provided the material be properly selected and the mode of presentation be not open to question. Already the channels are many and they tend to increase—the press, books, the Ministry of Health, "health weeks" in large provincial centres, the approved societies, health societies, the film, and broadcasting—a goodly array. I have already alluded in several places to the lay press. It is certainly the most powerful medium we possess for instructing the public on health matters. We must do our utmost to secure the coöperation of the proprietors and editors of those journals that influence the thinking public; their help is paramount. We need not despair of securing their assistance because, reading the placards on the backs of the 'buses, we find it difficult to believe that some newspapers will care much about printing health information of the orthodox kind. There isn't anything very "amazing" or "astounding" or savouring of a "shocking revelation" about exhorta-

tions to the citizen to clean his teeth, or to eat more vegetables, or even to "open that window—cover that food—kill that fly." Fortunately there are other journals. Even so, the iteration of such maxims as these must needs pall, and that rather quickly; it would soon develop into what an editor friend of mine terms "writing round the moon." And yet if we let the individual doctor loose the editor will quickly pick the man who has (for him) two assets—a journalistic style and a flair for peculiar views on pathology or treatment. The very qualities that damn him in our eyes render him a blessed acquisition in the eyes of the editor. In the words of the poet, "Who can do a thing, will not; and who would do it, cannot." What we should like the editor to do is to pick the same sort of man that he picks when he is ill, because we must remember, and the fact is pertinent, that the editor's doctor is not a publicist, nor does he hold peculiar views; he is just an ordinary practitioner like ourselves; he doesn't know the exact cause of cancer. If we yield on the gossip and the "story" (and I have yielded) the editor may be inclined to meet us on the instruction question, and accept control by the committee I visualised. We might have two or three editors on the committee. Anyway, we might have a conference with them on the subject.

What is the objection to such a method of controlling medical instruction as that which I am advocating? I can only think of one. It would probably be advanced that the publicity committee is a sort of medical hierarchy and that certain individuals who have the itch to write might not—and probably would not—be nominated to sit upon the board. But their effusions would in all likelihood get to the press all the same. The important point is that there would be the chance of an authoritative "health column," reading which the thinking subscriber to the journal might know that what it contained was endorsed by the censoring body. But the lay press must not clamour for the signed article by men in active practice. They will get it, they do get it, but they should leave it to the good taste of the doctor to refrain if he chooses. In proportion as the lay press succeeds in making us good journalists it will leave us bad doctors.

A correspondent—I wish his telegraphic address were not the name of a common disease—reminds me that an ex-Lord Chancellor writes much on many questions and that the Primate and the Dean of St. Paul's do likewise. Why not medical men, he asks? Waving the consideration that medicine should be permitted to aim at a higher standard of taste than the law and the church if it so desires, I can only reply to the question by suggesting that the conditions at the bedside and in the consulting-room are different from those of the courts and of the cathedral. It may be that the patient's jealous concern for his body weighs more with him than it does in respect of his honour or his soul; perhaps he knows that all three of these are often laid somewhat bare before the doctor's gaze. This being so, he feels that a flair for publicity is incompatible with that capacity for silence which patients have a right to demand from their doctor. It is essential to his proper treatment that we give him a complete sense of security. Considerations like these bring us, or so I believe, to the very crux of this publicity business, and I am saying how the matter appeals to me. The first objection to publicity on the part of members of our profession concerns the psychology of the patient, as just dealt with. The second objection concerns efficiency in relation to his diagnosis and treatment.

When a man falls sick what he needs are the care and skill and intelligent sympathy of a good doctor. He does not want a publicist to give him medical news or discuss a favourite theory or to put his own case before him with that "pep" which editors love to secure for their readers. If his disease be obscure, or be thought to be desperate, and his doctor considers it is in his interest that the doubtful points in his case should be hammered out—as they only can be with benefit—in technical language on the anvil of another doctor's mind, what the patient needs is a consultant having special experience of the type of disease in question. Again, if operative treatment seems necessary, the patient's recovery may turn upon the choice of a surgeon whose facility and technique in the particular type of procedure demanded by the case are well known to the doctor.

Now if the sick man, or his friends, be led to choose the doctor, or the consultant, or the surgeon, from any other reason than his known merits in relation to the particular functions he is required to fulfil, it is unlikely that the patient will get the best attention which the profession can offer him. If he argues that because Dr. or Mr. So-and-So's name is much "before the public," therefore he must be a good man, he may commit a very grave error. It is in order to save him from this error that publicity on the part of medical men must be avoided as far as possible. I would almost go so far as to say that the sick man may quite safely conclude that a doctor's capacity is likely to be in inverse ratio to the number of times his name appears in the lay press. No doubt there are some exceptions to this rule, as to many others; this meeting having earned a good deal of unenviable publicity already, I may say that I hope there *are* some exceptions. I would myself yield to the innumerable invitations, cajolings, compliments, threats almost, of editors and newspaper proprietors, and write signed articles to the press if I did not fear that I might thereby lose what I very much value, indeed, if I may be personal, what I value most in life, the confidence of my colleagues and their patients.

That is how I read the tradition of our profession in respect of this matter. Those who do not pause to think upon what grounds it is based, or who stand to gain an immediate advantage by its sacrifice, would have us depart from it. But I do not think that we shall depart from it. It is very ancient, dating from pagan times. This, of itself, is no reason for adhering to it, but since patients have the same fears and scruples as they had when Hippocrates practised medicine, we shall need greater inducements than any so far advanced before we break with it. As a friend of mine has epigrammatically put it: Shall our traditions be butchered to make a pressman's holiday.

If our friends of the press would accept these facts as our reasons against seeking publicity rather than suppose that we are only kept from this by fears of the General Medical Council and its punitive powers, they would understand us much better, besides paying us a better compliment. Publicity, as they well know, is not the same thing as prestige. It is almost impossible to acquire prestige and avoid some publicity. But it is possible to enjoy much publicity and still lack prestige. Nor does writing articles to the press necessarily bring patients. Amongst those letters to which I referred in my opening remarks was one from a doctor who told me that he had, in the course of the past 20 years, written close on 2300 signed articles in the lay press, yet, he says, "during that 20 years I have not succeeded in getting one single patient—desirous or actual—as a consequence (direct or indirect)." I don't think he meant to use the word "succeeded," but he did. Now, I have done better than that because, though I have never written a medical article in the lay press, I *have* had one patient, and I nearly had a second, as the result of being quoted in the newspapers. The patient I *did* get was brought to me only the other day by his doctor; he was suffering from hypochondriasis, and he had read something I had said about the bad effects of worry upon health. The patient I *nearly* got was, I fear, suffering from acute alcoholism. It was a night call on the telephone, to be exact it was 2.30 on a Sunday morning. When I was sufficiently awake to know what was being said the other end I found I was being addressed by the sergeant on duty at the Harrow-road police station. He had a man there charged with driving a car to the danger of the public whilst drunk—"very drunk" the sergeant said—and this

man wanted me to come up and testify to his sobriety. I naturally asked why he wanted *me*. It seems that on being charged the man denied that he was under the influence of liquor and, taking a newspaper cutting out of his waistcoat pocket, he pointed to it and said, "this is the doctor I want to examine me." The cutting (I regret to say it was the *Times*) quoted me as having said that I knew of no experiments, scientifically designed, which proved that the taking of alcoholic beverages in moderation was injurious to health. I acquiesced in the sergeant's suggestion that he should follow his usual custom and send for the police surgeon, but it is obvious that I could have had this second patient also had I wished.

But, speaking seriously, I agree with my correspondent when he says that the advertising value of signed articles in the lay press is over-estimated, always supposing them to be free from suggestions of special knowledge or unique skill. Despite the memorandum recently issued by the registrar of the G.M.C., it still seems to be widely thought that the Council forbids the writing of such articles, whereas it does not. The memorandum states "that the publication in the press of articles on medical subjects by medical practitioners has not been condemned by the Council, unless it has been proved that the articles were written, whether directly or indirectly, for the purpose of obtaining patients or promoting a practitioners's professional advantage."

Articles of this latter class are certainly discreditable to the profession and contrary to the public interest, for they conform to the methods of the unqualified practitioner. It was to enable the public to tell the qualified from the unqualified practitioner that the Act which brought the G.M.C. into being was passed, and it is therefore incumbent upon this statutory body to keep his distinction clear. The Act was clearly introduced for the benefit of those of the public who wished to know who was trained and had received a diploma, and who was not, for there were apparently some people in 1858 who considered this to be a point of importance. The preamble of the Act is brevity itself: "Whereas it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners: Be it therefore enacted . . ." There are always some persons who want to have their cake and eat it too. If we are on the Register we enjoy—or so it is supposed—certain advantages, but we are subject to disciplinary control. If we are not on the Register there is in this country no control whatever; the unregistered practitioner enjoys perfect freedom; he need not be even a gentleman. But we must choose one or the other; we must make up our minds what we want. *My* complaint against the General Medical Council is not its stringency, but its laxity. I know this is no fault of the Council, but the fault of its reference as laid down by law. If it were a vigilance body and acted on its own initiative it would surely round up a good many persons who succeed in driving a carriage and pair through those offences which the warning notice takes exception to. The Council is not only lax, it is also complaisant. Some time ago a doctor whose name had been erased from the Register after frequent and repeated efforts to attain this object wanted to get on it again because, as he confessed to me, the erasure hadn't brought him the success he anticipated. So he wrote an apology and his name was put back. He is still dissatisfied, though why I cannot make out from his long and rambling letters, for he was one of those who thought I should be helped by a statement of his views on this subject. There are seemingly some practitioners to-day who trail their coats and hope the Council will give them the advertisement of being struck off from the Register. They forget that one of the functions of the Council is to check advertisement and not to be a party to it.

To try to correct the many glaring misconceptions about the General Medical Council is outside the scope of my remarks. I only mention them because they are shared by many medical men with the public. There was a recent clamour to have laymen sitting on the Council, and doctors wrote to the press joining in the clamour. They ought to have known that there is nothing to prevent laymen being on the Council; indeed, of the 38 members no less than 23—more than half—may be laymen.

To return to the channels of dissemination of health instruction, time will not permit me to speak of the value of "health weeks," of health societies, and especially—as I should like—of the great help we can derive from broadcasting. I have not been unaware that I should be expected to deal with the vexed question of the lay press, and what I have said could not be further condensed without risking obscurity. But I have purposely left until now the mention of a medium excelling all of these just mentioned in potential value if it can be properly utilised, and that is the doctor himself. Personal contact of doctor and citizen is the best answer to the question "how to keep well." In this way and only in this way can the individual needs of the public be allowed for in health instruction. I heartily endorse Sir John Robertson when he says that "it is part of the duty of every medical practitioner to teach in such a way as will give information to his patients about the prevention of illness in addition to the cure of illness." Health talks and lectures by doctors working under the National Insurance Act to the patients on their panel are not only ethically correct, they are encouraged by responsible bodies and the machinery for developing this side of the doctor's functions is already available. Such duties cannot, of course, be gratuitous, and those men who are willing and qualified to carry out this valuable work should be adequately subsidised. These talks and lectures might be assisted by a series of leaflets properly controlled, perhaps provided by the Ministry, embodying the chief points dealt with.

Faced with all this health propaganda, it is to be hoped that the public will not take itself, nor us, too seriously. This is a danger we must try to avoid. There is an unattractive drabness about most of the present health advice, a sombre aceticism which, though doubtless of service both physically and medically, seems to me sadly to need relief. It would be a pity if the savour went out of life at the same time as the savoury things are taken from our diet. I am hopeful that it may not, even if some people do become austere and valetudinarian before their time. There is an inertia in the mass, and sometimes a rebel spirit which, though wept over by the health apostle, is not without its saving grace. A father writes to one of last month's health journals to say that in the council school of his town they have formed a "health brigade" and his little daughter Joyce, aged 9, is the captain. "My younger daughter," he adds, "says she will not join it, because she likes sweets." Some coercion appears to have been brought to bear upon this stout little protestant, for the letter proceeds to state that she had put her name to the bond, one of the rules of which was "to buy fruit instead of sweets." Conquered but unconvinced we may picture her, sitting apart, satisfying her natural craving for sugar in secret. The editor's note, whilst wishing good luck to the brigade, says, "this is the spirit we want to see in the rising generation." Of course he refers to the spirit of Joyce, the captain, aged 9. But I am glad to believe that the younger daughter is going to give health societies a lot to think about.

NORTH RIDING INFIRMARY.—The ordinary income for the half year ended in June last was £3000, compared with £4450 during the corresponding six months of last year. The loss of income is attributed entirely to the coal dispute.

AN INDIAN MILITARY HOSPITAL.—Last month the King of Nepal opened the Tribhuana-Chandra Military Hospital at Katmandu, which has been erected by the Maharajah of Nepal, the Hereditary Prime Minister, at a cost of £30,000, as a memorial to the Gurkha troops who served in the Great War. It has 64 beds, disposed in six wards of eight beds each for soldiers, 12 rooms with one bed each for officers, and one ward of four beds for isolation cases. Each ward is complete in itself, with kitchen, sun-porch, day-room, linen closet, and bath-room.

THE TREATMENT OF ANGINAL PAIN AND RAISED BLOOD PRESSURE BY DIATHERMY.*

BY JOHN HAY, D.L., M.D. LIVERP., F.R.C.P. LOND.,
PROFESSOR OF MEDICINE, LIVERPOOL UNIVERSITY; SEN. HON. PHYSICIAN, LIVERPOOL ROYAL INFIRMARY;
AND
PHŒBE INCE, M.D. LIVERP., D.P.H.,
CLINICAL ASSISTANT, HEART DEPARTMENT.
(*From the Heart Department, Royal Infirmary.*)

DIATHERMY can no longer be looked upon as an experimental method in treatment, but, although widely employed, its scope is not yet clearly defined, and this communication is made with the object of presenting the results of its application in a series of eight patients suffering from anginal pain and in six with marked hypertension, in one of whom intermittent claudication was the dominant symptom.

Diathermy is a form of treatment in which heat is generated in the tissues by the passage through them of high-frequency currents. It is essentially different from the warming of a part by the application of heat to the skin. Human tissues are conductors of an electric current, but they are conductors with a high resistance, and consequently the passage of an electric current through them generates heat.

Besides its surgical applications, diathermy has been used in a large variety of medical cases, as, for example, in all forms of neuritis, neuralgic pain, hæmorrhoids, gonorrhœa, paralysis agitans, cardiovascular disease, arthritis, and other disabilities. Dr. E. P. Cumberbatch has written fully on this subject, and Dr. F. H. Humphris speaks optimistically of its effects in hyperpiesia, where it causes a relaxation of the vessels. But, as the latter points out, there appears to be more than that. The patients themselves feel materially better, brighter, and more full of energy.

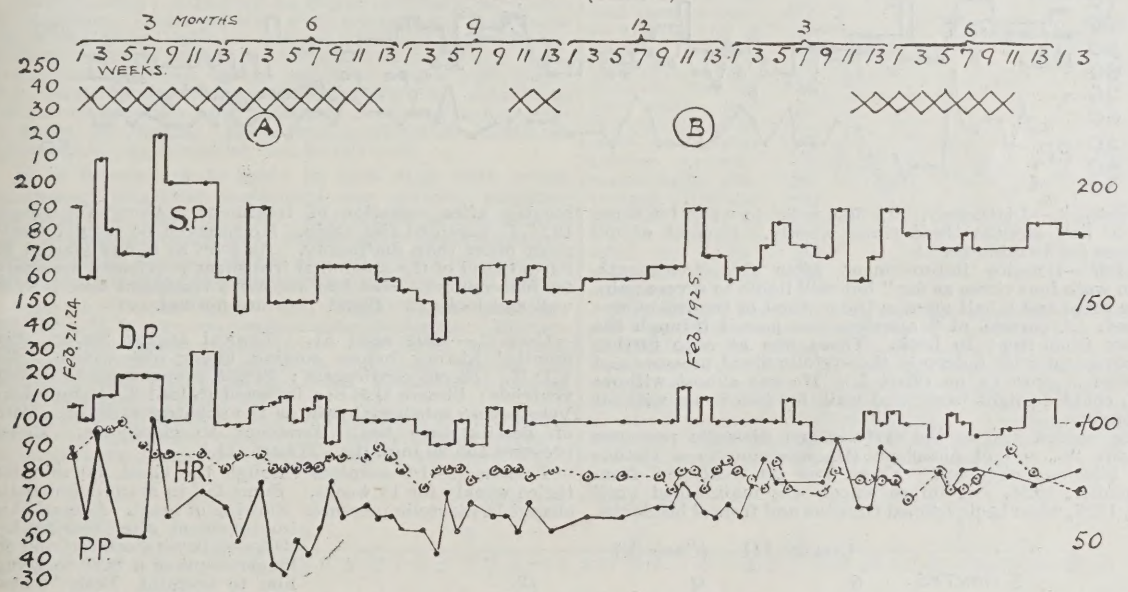
Anyone who has had personal experience of the effects of diathermy knows how the tissues through which the current is passing, slowly become warm until there is an actual sensation of heat, first locally, then the whole body becomes recognisably hotter, and sometimes frank sweating occurs.

Diathermy in Circulatory Disorders.

In February, 1912, Nagelschmidt published his classical paper in the *Roentgen Ray Archives* on the diathermic treatment of circulatory disorders, relating numerous cases treated by diathermy. Among these were cases of intermittent claudication, where the effect of suggestion could be fairly eliminated. The pathology of the condition is understood, and the clinical result of the change in the arteries is only too well known to the patient. Any prolonged or extra effort in the nature of walking produces a cramping pain in the foot and leg of such severity as to cause the patient to stop. The pain wears off gradually when the patient rests, only to return when walking is resumed.

The result of diathermy was dramatic. Walking no longer brought on a crippling cramp. The man who before treatment could only walk a few yards, after treatment walked miles with comfort. The application of diathermy restored the circulation to the legs, and the intermittent limp was no longer brought on by effort. This remarkable change, brought about by the action of diathermic currents on the arteries of the leg, is a strong inducement to attempt by like means to influence the circulation in other parts of the body. We applied the current to the chest, "through and through," in the hope that the coronary circulation might be improved, and also in order to determine how far the distress accompanying high blood pressure could be modified.

CHART I. (Case 1.)



The figures to the left of each chart represent the blood pressure in millimetres. The duration of the observations is indicated in weeks and months. S.P. = Systolic blood pressure. D.P. = Diastolic blood pressure. P.P. = Pulse pressure. H.R. = Heart-rate. The treatment is shown by a series of crosses just below the figures indicating the weeks.

For the last two years we have been observing the effects of diathermy on two groups of patients: 1. Cases of angina. 2. Cases of raised blood pressure with various associated symptoms.

This communication embodies the results of our investigations. Eleven of the patients have been under observation in the heart department of the Royal Infirmary over a considerable period, and records have been taken week by week of the fluctuations in blood pressure, both systolic and diastolic, and any changes in the general condition and symptoms have been noted.

The accompanying charts will enable the clinical course to be followed with ease.

The supervision of the administration of the diathermy has been carried out by our colleague

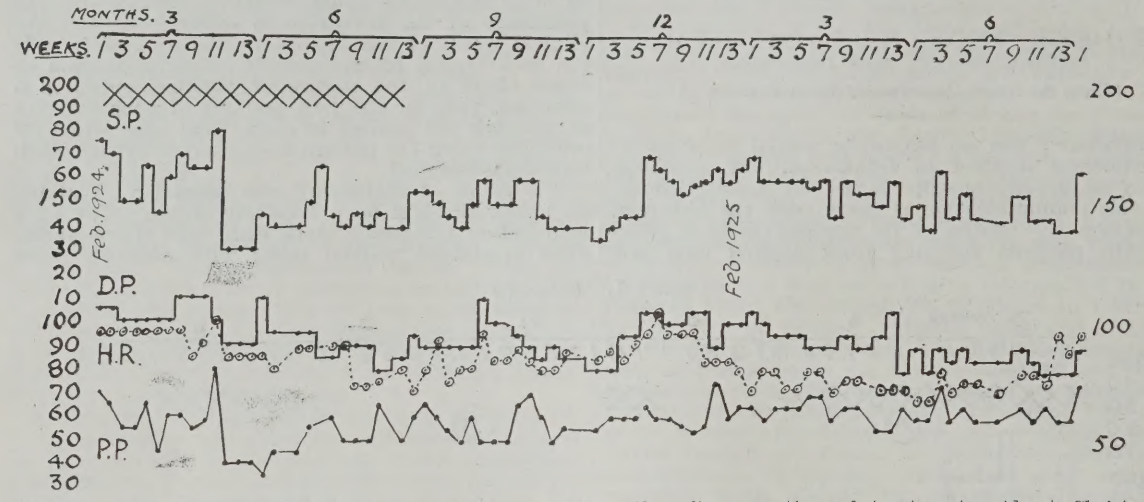
* An address delivered at University College, London.

at the Royal Infirmary, Dr. C. Beresford Alexander, to whom we are greatly indebted.

Clinical Records.

CASE 1.—Male aged 66. Angina minor, high blood pressure, 190/105 mm. Hg, and arterio-sclerosis. Electrocardiogram normal. Left ventricle plus. Gripping pain, substernal, on exertion. Dyspnœa moderate.

CHART II. (Case 2.)

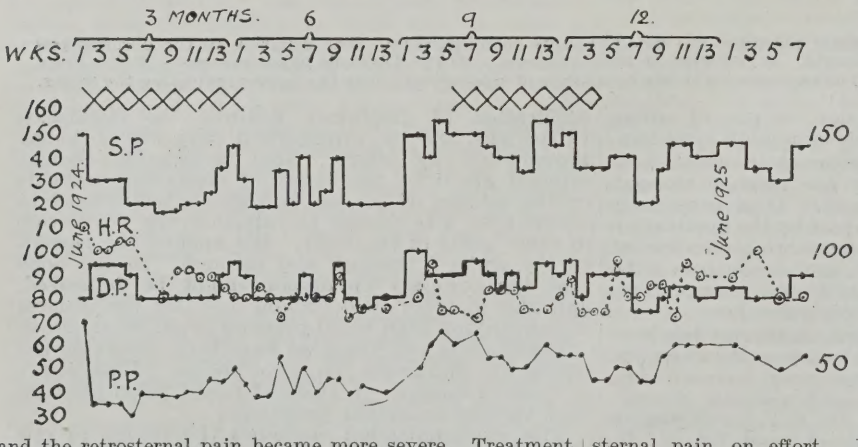


Treatment.—Diathermy. At first wrist to wrist for three and a half months three times weekly. Current of 0·9 ampères for 30 minutes.

Result.—Definite improvement after five treatments. "Can walk four times as far" but still liable to severe pain. After three and a half months the method of treatment was altered. A current of 2 ampères was passed through the thorax from front to back. There was at once further improvement with a drop in the systolic blood pressure and in pulse pressure (A on Chart I.). He was almost without pain, could do light work, and walk for two hours without discomfort.

The sudden rise in the systolic and diastolic pressures towards the end of his chart (B) was due to a riotous and hilarious week-end. There was no treatment from November, 1924, and improvement was maintained until May, 1925, when he developed tinnitus and frontal headache, and the retrosternal pain became more severe. Treatment was then resumed twice weekly. After some weeks symptoms were relieved and patient returned to work as an electrical fitter. Is keeping well. B.P. fairly constant; 180/100 mm. Hg. The last course of treatment, although relieving the symptoms, had little effect on blood pressure or heart-rate.

CHART III. (Case 3.)



CASE 2.—Male aged 70. Anginal pain. Six years' history, but pain was less severe at the time diathermy was commenced than it had been some years before. Dyspnœa on walking. Blood pressure 175/105 mm. Hg. Electrocardiogram: Left ventricle plus; T inverted in lead 1. This patient had been under observation and general treatment for some years before diathermy was administered. (Chart II.)

Treatment.—Through chest; 1·9 ampères 30 minutes, thrice weekly, followed by very definite improvement. "Looks younger and fitter. Walks without effort. Can play bowls for four to five hours with comfort, which he has not been able to do for years." Note the drop in systolic and diastolic blood pressure, maintained for four to five months after cessation of treatment. About Christmas, 1924, it began to rise again. He received no regular treatment other than diathermy. As soon as it was started he felt no need of the medicinal treatment previously necessary for his comfort. Has had no more treatment and is very well and looks it. Blood pressure normal.

CASE 3.—Male aged 51. Typical angina major. Six months' history before coming under observation. No V.D.H. Electrocardiogram: Slight preponderance of left ventricle; bizarre Q.R.S.; inverted P, lead 3. Symptoms: Very severe substernal pain on the slightest exertion. Pain on getting into bed. Tendency to glycosuria. Blood pressure 150/80 mm. Hg. (Chart III.)

Treatment.—1·5 ampères through the chest, 30 minutes thrice weekly for 14 weeks. Some fall in systolic but little change in diastolic pressure. Slowing of heart. Remarkable improvement after two weeks. "Can walk with comfort and no longer requires a taxi to bring him to hospital. Feels 'a new man.'" After six weeks' treatment "No pain, day or night; can walk much farther." Treatment was stopped for three and a half months, followed by some rise in blood pressure. He kept fairly well, but pain began to recur and treatment was resumed. Within a week after three treatments he was feeling considerably better. He still remains very well and looks it. Very rarely needs to take trinitrin; slight discomfort only on moderately severe exertion.

CASE 4.—Female aged 48. Angina minor with slight aortic regurgitation. Hypertension: 190/90 mm. Hg; H.R. 84. Electrocardiogram: Left ventricle plus. Gripping substernal pain on effort. Radiating to neck, lower jaw, and left arm. Smothering sensation in epigastrium. Dyspnœa on walking. No constant relationship to effort. W.R. ++. Diastolic bruit varies. Probably slight aortic lead. In 1919 had been operated on for gall-stones; gall-bladder not removed.

Treatment.—Diathermy: 0·6 ampères for 30 minutes thrice weekly, wrist to wrist. Result: Faintness while receiving treatment and refused further treatment. Afterwards gall-stone colic, but operation postponed. Diathermy caused fall in systolic and diastolic pressures with some general improvement. The systolic pressure fell from 190 mm. Hg to 160 and then to 155 mm. Hg, with a corre-

sponding fall in the diastolic pressure from 90 to 80 mm. Hg. This was maintained for some weeks after treatment ceased and then the pressures rose. The systolic pressure did not again reach 190 mm. Hg. She was put on antisyphilitic treatment, but she refused to continue attendance.

CASE 5.—Male aged 49. Hypertension: 210/130 mm. Hg. Albuminuria moderate. Electrocardiogram: Left ventricle plus; T. inverted in leads 1 and 2. Clinically: Pain in right side of the head. "Retrobulbar optic atrophy" right eye. Dyspnœa on exertion and general lassitude. (Chart IV.)

Treatment.—Diathermy, wrist to wrist, 0·9 ampères thrice weekly for five months. Resulting in a steady fall in systolic pressure and a rise in diastolic pressure. Improvement, clinically, began at once. He felt "done up" immediately after treatment; better next day. After two months' treatment could walk from the docks to the Royal Infirmary—at least two miles, and uphill. Ceased treatment and did not attend the clinic for 11 weeks. At the end of this time it was found that the pressure had risen to 230 mm. Hg. There was increased dyspnœa on exertion, but in other respects he was better than when he began treatment. He had several short attacks of cerebral claudication since January, 1925 (right arm and right side of face with loss of speech.) Steadily getting worse. Severe frontal headache.

October, 1925: Admitted to Royal Infirmary for course of diathermy. Improved after a few treatments. Headaches disappear during treatment and remain clear for some hours. Formerly were so severe as to make him weep with pain. Treatment six times weekly for three and a half weeks. B.P., no permanent change. Average 220/140; reduced to 190/135 immediately after treatment; returns to his usual in about two hours. There was considerable functional improvement, no headache, and he felt well.

It is interesting to note in this case that when treatment was first instituted the systolic pressure fell and the diastolic rose, with great improvement in the general condition, while later the treatment cleared away the headaches and added to his comfort without modifying the pressure except for a few hours.

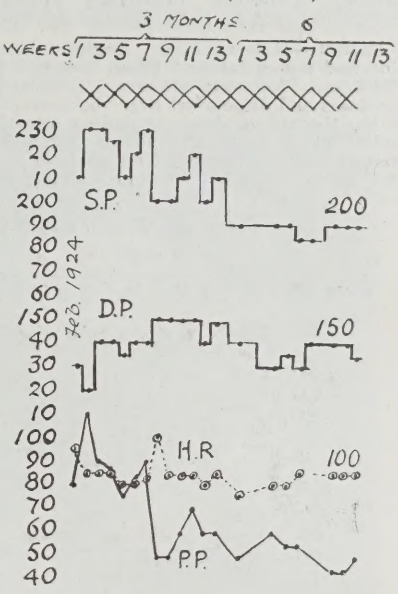
CASE 6.—Female aged 70. High blood pressure: 200/100; H.R. 80; no marked arterio-sclerosis. Electrocardiogram normal. Clinically: For three years had suffered from numbness of hands and arms, making her unable to work. Limbs always cold. Sensation of fullness in the abdomen. (Chart V.)

Treatment.—Diathermy 0·6 to 0·7 ampères, wrist to wrist. Result: Remarkable change in cardiovascular picture. Blood pressure returns to normal averaging 130 systolic and 90 diastolic; later 80 diastolic. Heart-rate lowered. Clinically: Improvement immediate and was maintained. She became *warm* and has remained warm. No longer any numbness of hands and arms. Although 70 she is able to get up at 6.30 A.M. and do her house work (including the weekly washing) without discomfort. Had previously done *no* work for three years. Still receives treatment twice weekly and is very well; aged 72. Blood pressure 128/78 mm. Hg.

CASE 7.—Male aged 47. Chronic interstitial nephritis. Extreme hypertension. 245/140; H.R., 96; arterio-sclerosis. Low urea concentration; N.P.N. 34 mg. per cent. Electrocardiogram: Left ventricle plus; T inverted, lead 1; Premature beats—auricular and ventricular. Clinically: Condition most unsatisfactory. Palpitation and dyspnœa on very slight exertion. Precordial pain. Huge heart. No. V.D.H.

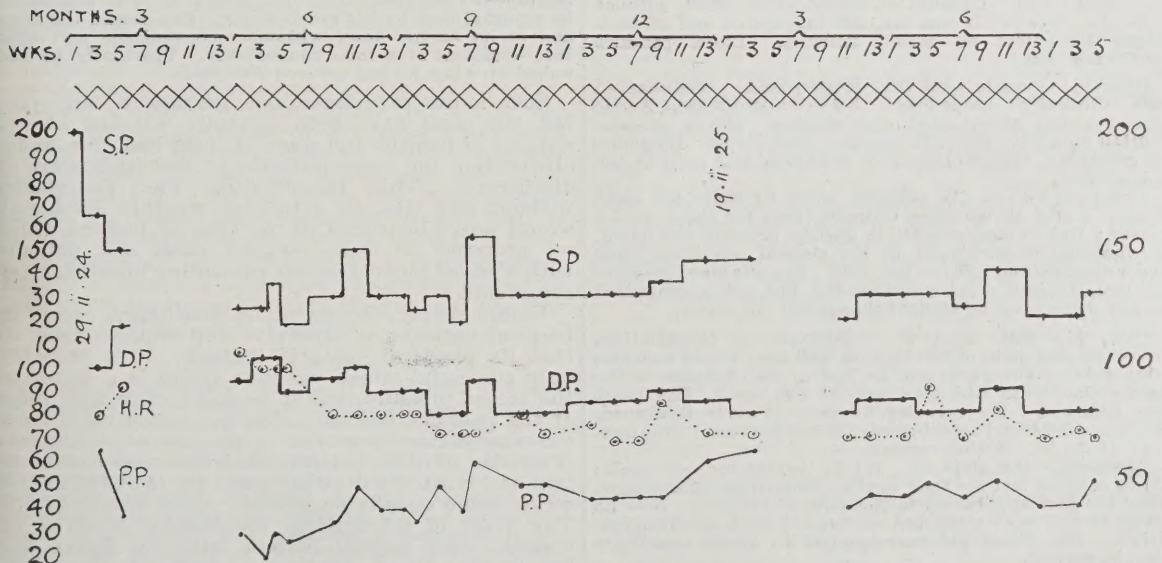
Treatment.—Diathermy, 0·9 ampères 30 minutes thrice weekly, wrist to wrist. Result: After two weeks' treatment felt much better and stronger. There was less palpitation and he was sleeping better. Each treatment caused a sense of exhaustion for 24 hours. After five weeks he felt so well that he went to Chester for a day's fishing (Oct. 4th, 1924). Walked four to five miles and *never recovered*, in spite of several further treatments with diathermy. Systolic pressure rose to 240 after the effort and he developed *pulsus alternans*.

CHART IV. (Case 5.)



The day at Chester exhausted him greatly, but he did not break down until a week later, when the pulse became alternating, the strongest beats being at 240 and the weaker at about 210. He then got steadily worse and was admitted to hospital in a month's time. When admitted the distress was considerable. There was an ominous fall in blood pressure—170/130 mm. Hg. Further treatment with diathermy was ineffectual and at his own request he was discharged. He died a few days later.

CHART V. (Case 6.)



CASE 8.—Female aged 52. Hypertension: 240/160; probably menopausal. Urea concentration below average; N.P.N. 33 mg. per cent. Electrocardiogram: Left ventricle +; inverted T in lead 3. Clinically: Shortness of breath on exertion. Flushings; flatulence; pain over left costal margin; palpitation. A miserable and querulous patient.

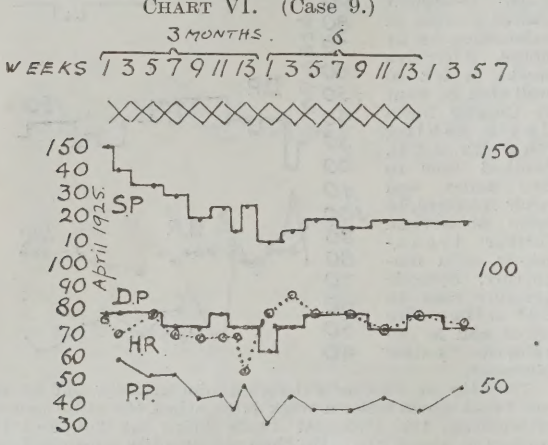
Treatment.—0·5 to 0·6 ampères; wrists; thrice weekly for three months. After that irregularly, because it caused such profuse sweating. Result: At first some improvement.

Felt "more sure of herself" and less pain. Latterly not much pain. There was a drop in systolic pressure from 240 to 190 mm. Hg during first four months and again on resumption of treatment. She had a further short course of diathermy in October, 1925, for two to three weeks, but gave it up after some improvement owing to sweating, chills, and bronchitis.

In this patient the result of treatment was unsatisfactory, although diathermy appeared to have a definite action in reducing the systolic pressure.

CASE 9.—Male aged 58. Angina minor. Aortic obstruction and regurgitation. Blood pressure 150/80; H.R., 80. Thickened, tortuous arteries. Clinically: Complains of tightness and discomfort over the sternum going on to pain in the throat, on effort, extending into the left upper arm, ending at or below the elbow. Some shortness of breath on exertion. His chest feels as if it were being gripped, and he is compelled to stop walking in order to obtain relief. (Chart VI.)

CHART VI. (Case 9.)



Treatment.—1·5 ampères for 30 minutes, six days weekly. Through the chest. Result: Dramatic improvement at once. Immediately after treatment he feels so well that he states he "could climb the side of a house." Is able to walk up hills without discomfort. Treatment, two days weekly, was continued until the end of September.

Has remained very well since he stopped treatment four weeks ago. Capable of considerable effort without pain—i.e., repairs his own car, lifts luggage on and off taxi. Slight discomfort on severe exertion. Blood pressure 120/75 mm. Hg.

CASE 10.—Female aged 46. Hyperpiesia. Well-marked case. Clinically: Large heart. No valvular disease. Aortic second sound accentuated and ringing. Blood pressure 280/150 mm. Hg. H.R., 72 regular. Symptoms: Dyspnœa on exertion. General feeling of weakness and pain in the epigastrium.

Treatment.—First 0·5 ampères wrist to wrist for eight weeks. Later 1·5 ampères through chest for three weeks. Result: Only a moderate fall in systolic pressure was noted. No material improvement in her general condition while under observation. November, 1925: Systolic blood pressure 225 mm. Hg, indicating a further fall, but not accompanied by any corresponding clinical change for the better.

CASE 11.—Male aged 63. Intermittent claudication. Weakness and pain in the legs on walking; would come on after walking 100 yards and he had to stop because of the pain. The "use had gone out of his legs." His heart was enlarged. No valvular disease. Vessels thickened. Aortic second sound accentuated. Blood pressure 170/95 mm. Hg; H.R., 80. Action regular.

Treatment.—0·8 ampères: (1) To ankles for one week; (2) to soles of feet for four weeks. Improvement appeared after the first application to the soles of the feet. Now he walks as well as ever and has returned to work as an engine-driver. His blood pressure dropped to 140/80 mm. Hg—that is, normal.

CASE 12.—Male aged 67. Angina minor. Blood pressure 230/115. Heart-rate 90. Electrocardiogram: Q.R.S. bizarre lead 3. Symptoms: Three years ago began to suffer, on walking, from a peculiar sensation across the sternum more to the right than to the left, which radiates into both arms as far as the wrists, compels him to stop, and then disappears. Two years ago, on account of the distress, had to give up golf. Heart enlarged; no valvular disease. Arteries tortuous. Urine normal.

Treatment.—Three treatments of diathermy, 40 minutes' arm to arm. No drug medication. Diet restricted. Feb. 16th' 1924: Blood pressure 165/100 after third treatment. Nov. 21st' 1924: It had risen to 185/95. Marked improvement.

"I have just returned from Scotland fit and well. Since I first took that electric treatment I have never looked back. I have dieted myself as per your instructions, but have taken no medicine beyond aperients. I can now walk any distance at a brisk pace without having to stop and rest. Weight about 11 st. 3½ lb.—about 4 lb. down."

CASE 13.—Aged 68. March, 1924. Angina. Blood pressure 160/90; H.R., 112. Electrocardiogram normal. Symptoms: Suffers from numerous attacks of anginal pain. First troubled him definitely about Christmas, 1923, but became much worse by the beginning of March, 1924. Gripping submanubrial and substernal pain brought on by walking, especially on an incline. Relieved at once by standing still and by the eructation of wind. No dyspnœa. A dull numb ache extends down the left arm. It either follows or precedes the submanubrial pain. Heart moderately enlarged; no valvular disease. No change in aortic sounds.

Treatment.—He was put to bed for five weeks and treated with diuretin and nitro-glycerine, but the attacks persisted, as often as 10 to 20 in 24 hours, though they were less severe than formerly. April 27th, 1924: Blood pressure 150/90. H.R., 96. Diathermy given three times weekly through the chest; 1·5 ampères. May 6th: Five hours after fourth treatment the blood pressure was 120/80 mm. Hg. Attacks just as frequent but less severe. June 19th: Material improvement. Blood pressure 135/85. Number of attacks halved, average now six daily as against 12 daily, and the severity much less. Diathermy was given at regular intervals.

My last note is January, 1925, from the doctor in attendance. "Much better in every way. Blood pressure 120/85 mm. Hg."

CASE 14.—Male aged 60. Sept. 11th, 1924. Angina major. Blood pressure 165/95; H.R., 88. Electrocardiogram normal. Symptoms: Anginal pain came on with the slightest exertion, such as easy walking or playing billiards. Onset of pain gradual, gripping in character, radiating to inner left arm and mid-forearm. He had led a very strenuous life, but had been free from illness. Pain was first noticed about the spring of 1923, but had been worse in 1924. He consulted a physician and was put on orthodox treatment without benefit; in fact, the liability to attacks increased. Heart slightly enlarged; no valvular disease. Bromides and diuretin with a carminative and amyl nitrite had no effect.

Treatment.—Diathermy: Thrice weekly through the chest undoubtedly improved him, although for the first week of treatment he became worse. On one occasion he was very giddy the day following a rather long application of diathermy—40 minutes. Oct. 10th, 1924: After 12 treatments he reported that he felt much better. Can ascend the steps and stairs at his hotel without inconvenience and walk three-quarters of a mile comfortably. Previously he had pulled up when he had covered 100 yards.

Such is our experience, not perhaps a large one, but the cases have been carefully watched over a number of months and some of them had been under observation for years previous to the application of diathermy. This investigation was undertaken without any bias, to determine whether diathermy would prove beneficial in the type of patient which we proposed to treat—anginal cases and patients with a raised blood pressure presenting unsatisfactory symptoms.

Unfortunately, treatment by diathermy, except in hospital patients, is expensive and requires time, so that its practical value is limited. It is probably only successful where vascular spasm is a factor in the raised pressure, but it is noteworthy that some of the patients had not obtained much relief from the vasodilators previous to the use of diathermy. A number of other patients have been under observation and treated with diathermy not included in this series, some equally successful, others disappointing. Two cases of intermittent claudication received no benefit. One anginal patient failed to derive any benefit when the electrodes were applied to the wrists, but noted immediate improvement when they were placed on the front and back of the chest.

Conclusions.

Certain conclusions seem warranted:—

1. The treatment did no harm. There were a few instances in which diathermy produced temporary dizziness and faintness or caused excessive sweating,

but these were the most distressing manifestations noted.

2. Nearly every patient expressed himself as feeling considerably better. The three unsatisfactory cases were females: (4) a syphilitic heart with anginal pain; (8) a menopausal hypertension where the diathermy caused very considerable sweating; (10) a case of extreme hyperpiesia with dyspnœa and general exhaustion as the dominant symptoms.

3. The charts show that in a number of the patients there was not only an immediate effect on the blood pressure, but that this improvement tends to persist for a time. And even if the pressure tends to rise later, the subjective improvement often persists.

4. Apart from the subjective improvement and the alteration in blood pressure, the capacity for effort has noticeably increased, vide Cases 1, 2, 3, 5, 6, 9, 11, 12, 14. Pain and dyspnœa were undoubtedly much less readily induced. In other words, the area of cardiac response was greatly increased and the patients were enabled to live more normal lives.

IODIDE ERUPTION

AN UNUSUAL CASE.

BY HENRY C. SEMON, M.D. OXF., M.R.C.P. LOND.,
PHYSICIAN TO THE SKIN DEPARTMENT, ROYAL NORTHERN HOSPITAL.

THE most common sign of cutaneous intolerance to halogen administration is a form of acne. It can usually be distinguished from the common variety by the absence of comedones and by a tendency to wander from the typical situations on face, chest, and back, to other parts of the trunk and to the limbs, where acne vulgaris is very seldom encountered. Rapid pustulation and the development of a congested mauve or purplish halo round the lesions may also serve to distinguish the medicinal eruption.

The granulomatous or tumour form of the eruption is rare and more commonly the result of bromide than iodide medication. The lesions appear rapidly either as pustules or purulent bullæ, with a predilection for the face and the extremities, frequently coalesce, and may then become papillomatous with a tendency to "fungate." Pain is slight or may be entirely wanting. Crusting and the discharge of a sticky yellowish pus from a number of points on the raised discoid lesions is a characteristic feature.

In addition to these two varieties of halogen eruption there are a bullous or pemphigoid and a type not unlike the manifestations of erythema multiforme. It must not be forgotten that the iodides may also produce catarrhal symptoms in the nose and throat with a tendency to œdema of the lids, while in some subjects the idiosyncrasy takes the form of pain in the joints, in the lower jaws, and in the long bones.

The following rare example of a granulomatous response to iodide of potassium was recommended for admission to the Royal Northern Hospital on June 28th by Dr. J. P. Hope, of N. Finchley.

History of the Case.

The patient, a married woman of 77, had been attending the out-patient department since April 13th for enlargement of the thyroid isthmus, and sepsis of the glands in the upper left cervical triangle. There were one or two small sinuses and several old scars which indicated the chronicity of the infection, and can be clearly seen in the accompanying photograph, overlying the thyroid gland and extending horizontally from right to left in the natural creases of the neck. The glandular enlargement is also apparent and is almost certainly the result of dental decay and oral sepsis, which was very severe.

The W.R. was negative. There was no history of any serious illness.

On the morning of June 24th the patient awoke with a swollen face and the lids so puffy that she could not open or see out of the right eye (the left eye was destroyed by an accident many years ago). She could, however, feel some blisters on the nose and cheeks. Two days later the swelling of the face had subsided sufficiently to permit of vision, and it was then apparent that the eruption on the face was assuming formidable proportions and that pustules were appearing on the backs of both hands, legs, and feet.

Characters of Eruption.—The facial appearance of the patient is depicted without any exaggeration (rather the reverse) by the photograph, which cannot, unfortunately, reproduce the dark red to purple colour of the raised, soft, fungating discoid lesions, the size of which may be gauged by comparison with the nose or orbit. All of them were slowly discharging a thick, grumous, sticky fluid which rapidly caused crusting and rendered dressings exceedingly difficult and tedious. On the extremities the lesions were pustular in type and showed no tendency to fungate. During the next two days in hospital fresh lesions appeared on the forehead, the right upper lid, and the scalp. At their

incipience these were of bullous type, but the contents were purulent and on rupture of the thin roof the granulomatous base rapidly proliferated, and in a few hours came to resemble the discoid mushroom-like character of the primary lesions on the face.

The mucous membranes were not affected at any time during the illness. The distribution, rapid evolution, and appearance of the eruption were, in my experience, consistent only with a halogen ætiology, and the urine was therefore submitted to Dr. P. O. Ellison (assistant pathologist to the hospital) with the suggestion that bromides might be present. These, however, could not be detected on repeated examination, although "traces" of iodide were found on two separate occasions. The urine was normal in other respects. The patient denied taking any medicine except that prescribed by Dr. Hope, and of that, she assured us, she had taken only two doses, both on June 21st. On inquiry Dr. Hope kindly informed me that this mixture contained iodide of potash, gr. 5 to oz. ½ of inf. gent. It therefore transpired that only 10 gr. of pot. iod. had been administered, and that the extensive eruption had supervened in three days. If the patient's assertions are believed the idiosyncrasy here present must surely be unique.

The treatment adopted was to utilise the "mass action" of sodium chloride originally suggested for bromism by Prof. U. J. Wile,[1] of Ann Arbor, Michigan, and elaborated by Stevenson.[2] The salt was given in gelatin-coated capsules in a dose of 10–20 gr. thrice daily after food. I was unable to convince myself that the administration of sodium chloride in this case had anything like the dramatic effect that it appears to exercise in cases of bromide eruption.[3] The patient made a slow but uneventful recovery, and

[3] Brit. Med. Jour., 1926, i., 372.

at the time of writing (August 9th), five weeks after admission, all the lesions have involuted with the formation of very small puckered scars, which will scarcely leave any permanent relic of the disfigurement suggested by the photograph.

THE INTRACAPSULAR OPERATION FOR CATARACT EXTRACTION.

BY GRAYDON HUME, M.B., B.S. LOND., D.OPHTH. OXF.,

LATE HOUSE SURGEON, ROYAL WESTMINSTER OPHTHALMIC HOSPITAL; CHIEF CLINICAL ASSISTANT, OPHTHALMIC DEPARTMENT, GUY'S HOSPITAL.

THERE is no doubt that the method for the extraction of the cataractous lens, complete with the whole capsule attached, is one which should be practised only in specially selected cases. Furthermore, this operation requires a greater degree of skill and more specialised technique than the old-fashioned method of cataract extraction in which the posterior capsule of the lens and flaps of the anterior capsule are left behind. Lieut.-Colonel Smith and other operators in India have done many hundreds of cases of extraction of the lens with the capsule complete, and there is no doubt that they have achieved a high percentage of remarkable successes. But we must remember that conditions in India are different, both as regards the material on which to work and also the psychology of the patient. The poorer type of patients in India, as is well known, journey large distances in order to have the operation performed, and are very adverse to the idea of having a two-stage operation, not to mention the possibility of returning later for a subsequent needling. Thus, when the cataract is bilateral, it is the custom to perform the operation on both eyes at the one time.

While in San Fransisco in July of last year I was much impressed by the excellent technique for the intracapsular operation which two brothers, Dr. Louis and Dr. Aaron Green, have evolved as a result of much experience and experimental investigations. I will say in passing that the Drs. Green are master technicians and work together admirably. They lay considerable stress upon the importance of choosing the right type of patient and the correct condition of the eye and orbit before this particular operation. They favour the so-called cadaverous type of orbit with very little orbital fat and sunken eyeball. As a primary consideration, they maintain that the method of deep infiltration orbital anæsthesia is the best preliminary to their operation. For a considerable time injections of novocaine solution into the back of the orbit have been given prior to enucleation of a diseased eye. For this technique of anæsthesia we are indebted to Lowenstein, of Prague, who published in 1908 his account of the method.

Method of Anæsthesia.

Since then Duverger and others have modified the technique somewhat. It is well known to every ophthalmic surgeon that the performance of an iridectomy under cocaine is usually attended with a sharp twinge of pain, which may lead to an involuntary movement on the part of the patient, sufficient to jeopardise the after result. Therefore, in place of or in addition to the method of Koller, who first instilled cocaine for anæsthetic purposes into the anterior chamber in 1884, we must avail ourselves with advantage of the deep injection of novocaine solution. The technique of the brothers Green consists in preliminary thorough sterilisation of the skin of the lids and that surrounding the orbit by first wiping it with benzine to remove the grease, followed by application of a 3 per cent. tincture of iodine, and finally by removing as much of the iodine as possible with alcohol. As a further precaution, it is their custom to shave the brow the night before operation. The lower border of the orbit is defined, and a point is chosen just lateral to the outer third of the lower margin. From here a long straight needle is pushed through the skin for a distance of about 4 cm., with its point directed inward and slightly upward between the inferior and lateral recti muscles. About 1 c.cm. of the 4 per cent. solution of novocaine with adrenalin is injected, and as the needle is gradually withdrawn, another c.cm. is emptied in the track of the needle, care being taken that the fluid does not puff out the subconjunctival space. It will be remembered that the ciliary ganglion lies between the optic nerve and the lateral rectus muscle, and it is in this region that we distribute the pressure of our solution.

In addition to the resulting inhibition of sensory impulses of a painful nature, the backward traction of the recti muscles (which is a frequent cause of loss of vitreous) is minimised. The palpebral fissure widens, the eye becomes more prominent and does not tend to shift about, making the operation for glaucoma or cataract much easier. The brothers Green report that in a series of 600 cases thus treated there were no cases of infection of the cellular tissues of the orbit, and only one hæmorrhage posterior to the eyeball, which happily resolved.

It might be anticipated that there would be a resulting liability to partial paralysis of the external ocular muscle, but this is not found to be the case. To complete the anæsthesia, about 4 c.cm. of the novocaine solution in question are used to infiltrate the upper and lower lids. Finally, about 1 c.cm. of the solution is injected from the external canthus laterally, with a view to striking certain twigs of the facial nerve, and as a preliminary to an external canthotomy.

One cannot lay too much emphasis on the fact that anæsthesia is only complete after a lapse of 45 minutes, and the great danger lies in operating too soon after the injection. It is highly important that the novocaine used should be that from sealed ampoules which have been sterilised.

Technique of Extraction.

The operation itself for the extraction of the cataract with the complete capsule attached, as performed by the Drs. Green, is a masterful performance. Perhaps in no other operation is a highly skilled assistant so imperative as it is in this operation for cataract extraction. The upper lid is held upwards by a special shelf-like lever directed from the lateral position by the assistant, the lower lid is slightly depressed by the forefinger of the other hand of the assistant. It is thus obvious that the usual speculum is entirely dispensed with. The usual incision for the extraction of cataract is made with the Graefe knife. At this stage a buttonhole or larger iridectomy is made. Then the small suction cup is introduced to fit on the anterior surface of the lens and capsule, and when it is realised that the suction has firmly gummed the capsule to the mouth of the instrument, the latter is deftly removed from the anterior chamber holding the capsule and contents firmly in position. It is of great importance to emphasise here that the technique of the Drs. Green differs very considerably from that of Barraquer. In the method just described, suction only is used to draw out the lens with its capsule, and no vibrations or trembling movements are required to rupture the zonule of Zinn. The fluid used in the pump is oil of a special specific gravity and viscosity, and further, it is most important to remember that there is a double lever control for the graduation and stoppage of the negative pressure.

While in San Francisco I witnessed the performance of eight intracapsular extractions of the lens on selected cases. In no case was there any loss of vitreous, and I was considerably impressed with the beautiful black round pupils, healthy condition of the globe, and excellent vision which resulted afterwards

This operation is most desirable only for selected cases; the skilful technique and excellent results of the Drs. Green have only been attained as the result of rigid asepsis, long research, and extensive experience.

THE RATE OF SEDIMENTATION OF RED BLOOD CORPUSCLES IN PULMONARY TUBERCULOSIS.

BY R. C. WINGFIELD, M.B. OXF., M.R.C.P. LOND.,
AND
R. GOODMAN, M.R.C.S. ENG., L.R.C.P. LOND.,
BROMPTON HOSPITAL SANATORIUM, FRIMLEY.

OUR excuse for this paper, on a subject already so widely discussed, is that we have made an attempt to determine the exact practical value of the rate of the sedimentation of red blood corpuscles in the diagnosis and prognosis of pulmonary tuberculosis. The literature is vast, and we have made no attempt to give any references.

Technique.

We have used the method of Linzenmeier.

Apparatus.—(1) A 1 c.cm. glass syringe divided into tenths. (2) Test-tubes about 6 cm. high of 5 mm. calibre. 3. Freshly prepared 5 per cent. sodium citrate solution.

Procedure.—The test-tube must be scrupulously clean and dry. The syringe and needle must be rinsed with the citrate solution. 0·2 c.cm. of the citrate solution is taken up into the syringe, and 0·8 c.cm. of blood is withdrawn from a convenient vein with as little stagnation as possible. The syringe is inverted several times to mix the blood and citrate solution, then, with the needle still in situ, the contents are expelled into the test-tube, care being taken to avoid bubbles. The tube is then placed in a perpendicular position, and kept at room temperature.

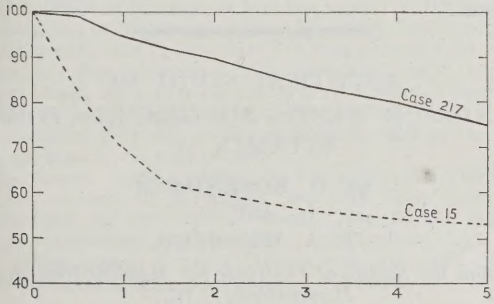
Reading Results.—The distance between the top of the column of blood corpuscles and the bottom of the meniscus of the supernatant fluid is measured every half an hour for the first two hours, and after hourly up to five hours.

The results were graphed, the ordinates being the percentage which the corpuscle column bears to the whole column, and the abscissæ the time in hours.

It was found that the readings during the first two hours were all that were necessary, and that for practical purposes a reading of 90 per cent. or over in the first hour could be considered within normal limits. For the graph of the sedimentation rate of a normal person depicted by this method is almost a straight line, while that of an abnormal condition appears as a curved line, the maximum fall occurring within two hours, after which time the curve flattens out (Fig. 1).

Fig. 2 is given to show the importance of the correct proportion of blood to citrate solution. Any decrease below 80 per cent. of blood tends to produce a sedimentation rate which approximates to normal even in an abnormal condition.

FIG. 1.



Showing a normal and an abnormal graph.

FIG. 2.

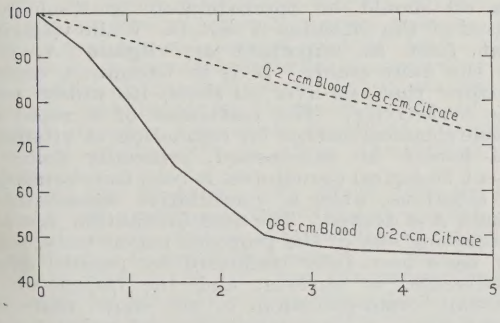


FIG. 3.

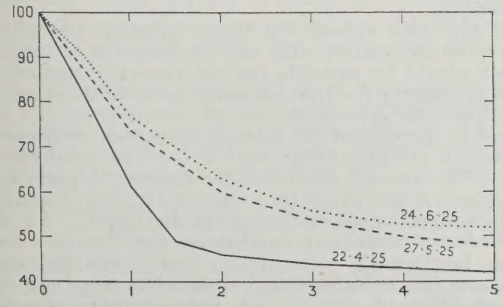
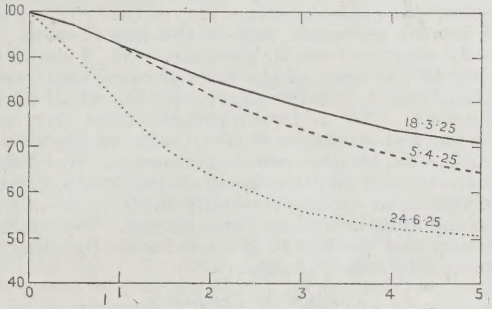


CASE 47.—Showing decreasing abnormality of the graph with improvement in health.

FIG. 4.



CASE 27.—Showing increasing abnormality of the graph with extension of disease.

FIG. 5.

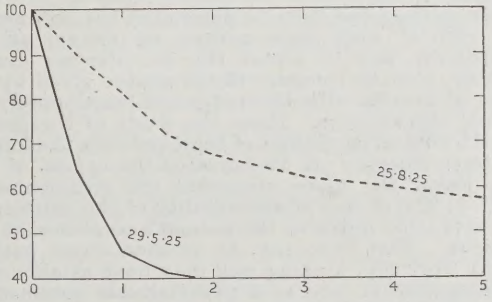


FIG. 6.

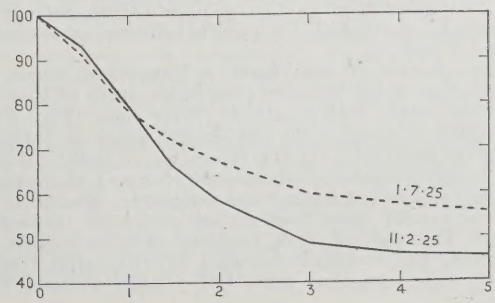

Value in Diagnosis.

The material used for these tests was as follows :—

Cases definitely diagnosed as chronic pulmonary tuberculosis (all adult males). Of these, with T.B. in sputum, 131 ; without T.B. in sputum, 25	156
Normal persons with no evidence of disease	8
Disease of the lungs in which tuberculosis was definitely excluded (all adult males). Of these, bronchiectasis, 2 ; lung abscess, 1 ; G.S.W. of chest, 1 ; syphilis of lung, 1	5
Other diseases in which no evidence of tuberculosis was detectable, and in which there was no evidence of any suppurative condition (adult males and females). Of these, diabetes, 6 ; carcinoma, 4 ; morbus cordis, 5 ; cerebral hæmorrhage, 2 ; gastritis, 2 ; Graves's disease, 2 ; fracture, 1 ; aneurysm, 1 ; lymphatic leukæmia, 1 ; subacute appendicitis, 1 ; pernicious anæmia, 1 ; spastic paraplegia, 1 ; hernia, 1 ; epilepsy, 1 ; club-foot operation, 1	30

Results.

	Sedimentation rate curves. Per cent. Abnormal.	Normal.
1. Of the 156 cases of chronic pulmonary tuberculosis	91·00	9·00
2. Of the 131 T.B. present in sputum cases	92·40	7·60
3. Of the 25 T.B. not present in sputum cases	19·04	80·96
4. Of the 8 normal persons	12·50	87·50
5. Of the 5 non-tuberculous lung disease	100·00	—
6. Of the 30 other diseases	86·70	13·30

The results 1, 2, and 3 show that while a definite case of chronic pulmonary tuberculosis usually gives an abnormal sedimentation curve, there is an error of at least 7 per cent., and in the less obvious cases the error may be over 50 per cent. No. 4 shows that roughly 10 per cent. of the normal cases may give an abnormal curve, but the figures are too small to draw conclusions. No. 5 is important, since five cases, where the test might be of great value in the differential diagnosis, all gave abnormal curves. No. 6 shows that an abnormally increased sedimentation rate is too common in disease generally for it to be of much use in the diagnosis of any one disease. We conclude, therefore, that the test is of no value in the diagnosis of pulmonary tuberculosis.

Value in Prognosis.

To estimate the value of the sedimentation rate in the prognosis of pulmonary tuberculosis is difficult, but we have come to the conclusion that it is of distinct value under certain conditions of medical practice.

Our method has been to determine the sedimentation rate of each male patient on arrival at the sanatorium, and to repeat this at intervals during his stay, then to compare the prognosis given by his series of graphs with the prognosis based purely on clinical observations. From the study of the graphs and the clinical conditions of these patients the following facts emerge : 1. The greater the extent of the lung lesion the more abnormal the sedimentation rate. 2. The degree of abnormality of the sedimentation rate is no index to the patient's condition at the moment. That is to say, an ex-sanatorium patient on full work and keeping well may have as abnormal a sedimentation rate as a pyrexial case confined to bed. 3. Apparent clinical improvement or lack of improvement is associated with a decrease or an increase in the abnormality of the sedimentation rate, but this alteration in the sedimentation rate could always be predicted by careful clinical observation (Figs. 3 and 4).

The graphs of two further illustrated cases are included in order to show that the results of this test must be read with caution. One case (Fig. 5) in particular whose graphs are shown raises an interesting point as to how far the alteration in sedimentation rate is influenced by tuberculosis per se ; it suggests, as has been noted by several observers, that it is the destruction of lung tissue that plays an important part. The patient was making excellent apparent progress, which was confirmed by the improvement in the sedimentation rate, but within a short time of the taking of the second reading he developed a tuberculous elbow, and his symptoms suggested that this new lesion may have begun even before the second reading was taken.

The graphs of another individual case are included (Fig. 6) as they seem to have a bearing on the same point. The second graph showed a distinct improvement, commensurate with that suggested by clinical observation. But within a few days the patient had a smart febrile relapse, a definite one, though it certainly was of no great duration. This second example suggests that the sedimentation rate is not a very delicate test of the position in which a patient stands in relation to his tuberculosis, but that it must be looked upon as an indication of improvement or lack of improvement of the general condition as a whole.

Conclusions.

We must therefore admit that when close clinical observation is possible the sedimentation rate is of little value. But many cases of pulmonary tuberculosis have to be treated under conditions where such clinical observation is not possible, in the out-patient department, the dispensary, and in private practice. And under these conditions, so simple and quick is the technique involved, that the test should prove of great value to the physician in his ponderings over such difficult questions as " Is this patient holding his own or not ? " " Am I justified in putting this patient to the trouble and expense of a more drastic form of treatment than I am giving him at present ? "

A CRITICAL STUDY OF COLOUR TESTS SUGGESTED FOR VITAMIN A.

BY O. ROSENHEIM
AND
T. A. WEBSTER.

(*From the National Institute for Medical Research, Hampstead, N.W.*)

THERE is general agreement as to the desirability of guaranteeing, by appropriate tests, that cod-liver oil should be approximately constant in its content of the vitamins A and D. While vitamin D is at least as important as vitamin A, it is also the more stable. It is in vitamin A content, therefore, that cod-liver oil shows its widest variations in activity. The usefulness of a rapid and reliable chemical method for estimation of vitamin A need hardly be emphasised, especially since the present biological growth-test is both time-consuming and laborious, when a quantitative assessment of vitamin A is desired. The need for caution, however, in accepting any of the proposed colour tests, before they have been fully confirmed by parallel animal experiments, is obvious, and the object of the following communication is to show that one, at any rate, of these tests has no value for the purpose intended, and may therefore be seriously misleading.

Of the two colour reactions recently brought to notice as associated with the presence of vitamin A, either would be suitable for colorimetric application if its specificity for that vitamin were established. In the first, discovered by one of us,[1] a transient blue colour is developed by adding arsenious chloride (or antimony chloride, Carr and Price [2]) to cod-liver oil, and in the second, described by Fearon,[3] a permanent red colour is produced by pyrogallol in the presence of trichloroacetic acid and an oxidising agent. We have worked out standard conditions for the two tests, using Lovibond's colorimeter, which enabled us to compare the colorimetric values of a large series of oils of different origin with their growth-promoting power, as tested by feeding experiments on rats.

Two Entirely Different Colour Reactions.

We soon recognised that the two colour reactions are due to two entirely different chromogenic substances. They differ in their behaviour towards solvents and can be quantitatively separated from each other in one operation, by saponification of the oil. It is now definitely established that the whole of the growth-promoting property of an oil is contained in the unsaponifiable fraction, and that the soaps are devoid of activity. When an active oil is saponified it is found that the ether extract, prepared with the usual precautions to prevent destruction of the labile vitamin, gives the $AsCl_3$ reaction with increased intensity, quantitatively proportional to the amount of "unsaponifiable," whilst the pyrogallol reaction is entirely negative. On the other hand, the soaps retain the whole of the chromogen reacting with pyrogallol; this chromogen was subsequently found to be associated with the unsaturated fatty acids. These facts alone furnish decisive chemical evidence against the view that Fearon's reaction is related to vitamin A.

An equally decisive answer was hardly to be expected from the biological tests, since all active cod-liver oils tested gave both the colour reactions (although apparently in different and unrelated proportions), and all inactive vegetable oils were negative to both tests. In the course of an investigation in which we examined the oils of livers not only of the cod-fish, but of other animals as well, we found, however, another class of oils and fats which are positive to the $AsCl_3$ reaction and negative to Fearon's test. In these the presence of vitamin A had been proved by previous feeding experiments on rats. In every instance these fats gave the $AsCl_3$ reaction,* in some cases with many times greater intensity than cod-liver oil. On the other hand, only fish liver oils give Fearon's reaction. This reaction is entirely negative in the case of the liver oils of all birds so far examined, and in the liver fats of nearly all mammals.

We found, further, that the body-fat of the animals so far examined is either entirely free from the chromogen of the $AsCl_3$ reaction (as in the case of marine animals), or contains only traces of it. On the other hand, some of these fats are rich in the material giving rise to Fearon's reaction.

Biological Test.

In order to obtain a clear-cut answer from the feeding experiments we selected for the biological test two oils, easily available in sufficient amount, one of which (sardine oil) gave a positive reaction with Fearon's reagents and none at all with $AsCl_3$, whilst the other (pig's liver fat) reacted in the opposite sense. The feeding experiments were carried out by the technique introduced by Drummond, Coward and Handy,[4] in which a constant supply of vitamin D (irradiated cholesterol) is given throughout the experiment.

Through the kindness of Dr. H. H. Dale we were enabled to test a sardine oil,† which had been sent to him by Prof. Poulsson, of Oslo, as possessing an extremely low or no growth-promoting activity. This oil was entirely negative in the $AsCl_3$ test, but gave a Fearon's reaction of an intensity corresponding to an average cod-liver oil. On the basis of the latter test sardine oil should be rich in vitamin A, but the animal test, carried out by us, showed it to be entirely devoid of this factor; the oil neither caused growth under the conditions indicated above, nor had it any effect on xerophthalmia.

The fat prepared from pig's liver was entirely free from the chromogen reacting with pyrogallol, but a quantitative colorimetric test with arsenious chloride (or $SbCl_3$) showed it to contain about twice the amount of chromogen reacting with $AsCl_3$ as compared with a good sample of cod-liver oil. The solid fat was dissolved in liquid paraffin and administered in doses equivalent to half the doses found to be efficient in the case of the cod-liver oil. On the basis of the Fearon test, this fat should be devoid of growth-promoting activity, whilst it actually produced as good growth as double its amount of cod-liver oil. This fat also induced a rapid cure of xerophthalmia.

As regards Fearon's test, therefore, the evidence appears to be quite definitely against its having any relation to vitamin A, for the estimation of which it was suggested. In the case of the colour reaction with $AsCl_3$ (or $SbCl_3$) the possibility of a direct relation of the chromogen to vitamin A remains open. Such additional evidence as is here presented is quite compatible with its specificity; but no conclusion would be justified until yet further evidence has been obtained.

Effect of Exposure to Light and Air.

In connexion with these colorimetric tests some experiments may be briefly mentioned in which the effect of exposure to light and air on cod-liver oil was examined by parallel colour and feeding tests. It was found that the $AsCl_3$ colour reaction disappeared together with vitamin A (as tested on the animal) when cod-liver oil was kept in loosely stoppered glass bottles exposed to light under laboratory conditions for eight weeks (see also Peacock[5]). Since we had previously observed that the chromogen responsible for the $AsCl_3$ reaction is rapidly destroyed by organic peroxides the exposed oil was examined by various characteristic tests. The guaiacum test with peroxidase (from horse radish) was found to give a strong reaction. A distinct positive reaction was obtained with dilute blood (and guaiacum) and a strong reaction with potassium iodide-starch solution. Seven different samples of ordinary cod-liver oil, kept in the dark, were also tested, and of these one did not react with the $AsCl_3$ reagent. This particular oil gave a strong peroxide reaction and was found inactive in the growth-test. When mixed with an active sample of cod-liver oil it rapidly destroyed in this the chromogen of the $AsCl_3$ reaction (see also Fridericia[6] and Sjörslev[7]). It would therefore seem that the peroxide reaction deserves to be considered in further work, in conjunction with other tests, when judging the vitamin value of cod-liver oils.

The destructive action of both light and air on vitamin A is well known, and it is surprising that this knowledge has not yet led to the more general supply of the oil in small bottles of brown glass.

The experimental details of this preliminary communication will be published elsewhere.

* In this connexion it might be mentioned that the livers of rats on a diet deprived of vitamin A no longer possess any growth-promoting activity, and, as we have found, their fat no longer reacts positively with $AsCl_3$.

† European sardine oil is obtained from the heads of *Clupea sardinus* in the preparation of tinned sardines, Japanese sardine oil from *Clupanodon melanosticta*. We have no information as to the origin of the oil supplied by Prof. Poulsson.

BRIGHTON POOR-LAW INSTITUTION.—"The position is wrong, the accommodation as proposed is poor and inadequate, and only a makeshift, extensions are not possible, and there is also a considerable waste of space by reason of the conversion of a building not adapted to the new use. Sooner or later a suitable nurses' home will be essential; therefore the present proposed expenditure is neither well spent nor economical." Despite this scathing criticism by the Ministry of Health, the Brighton Guardians, by 16 votes to 14, on Sept. 21st, declined to have plans prepared for a new nurses' home, being of opinion that the present time is inopportune for building. The guardians' proposal is to adapt the existing premises at a cost of over £1150 rather than embark on a scheme involving a much higher expenditure. This was the proposal turned down by the Ministry. Brighton is a large town with a growing population. The Poor-law institution on Sept. 21st had 432 inmates in the infirmary and 307 inmates in the other portion, a total of 739. These numbers are likely to increase rather than decrease.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

THE opening meeting of this Section was held on Oct. 8th, Sir HERBERT WATERHOUSE, the President, in the chair.

Multiple Bony Lesions.

Mr. J. H. SHELDON showed specimens from a case which was exhibited to the Section last November as one of multiple bony lesions. Seen in life on that occasion, he was a boy aged 20, whose family history presented nothing unusual. At 11 years of age a hard lump appeared on the outside of the right knee, but caused no inconvenience. It was regarded as an osteoma of the head of the tibia, and was excised. At the operation the tendon of the rectus femoris was seen to be studded with multiple fibromata. Four years later there was a recurrence of the lump, but without pain. Its increase, however, interfered with his work, and a large osteoma was removed from the right knee. Soon after his discharge from hospital growths began to appear in other limbs. One, on the right wrist, began as a soft painless swelling. Fomentation caused it to burst, and thick yellow pus was exuded. This, up to last year, had not healed. Similar swellings appeared and ran a like course, on the right elbow, on the back of the right arm, and in the right axilla, but these latter healed. In May, 1925, the right shoulder became the seat of a similar swelling, and that had been more painful than the others. It was, when Mr. Sheldon saw him, tense and there was marked fluctuation, with reddening of the skin. Movement at the shoulder was almost lost. The fluid withdrawn from this constantly increasing swelling was sterile and free of cells. It showed the absorption spectrum of urobilin, and gave a positive van den Bergh reaction. Skiagrams showed expansion of the upper third of the humerus, with destruction of bone and loss of the normal outline. There was, however, still the formation of new bone. The glenoid cavity was destroyed, and the coracoid process partly so. In the skull the patient had an exostosis arising from the external occipital protuberance; a general thickening of the bones of the vault; the pituitary fossa was deepened; there was an irregular outgrowth of bone from the inner table of the frontal bone and the roof of the orbital cavity, and an irregular thickening and new formation of bone on the floor of the skull in the region of the condylar processes. The boy's hands and feet were large in proportion to the remainder of his body. A relative lymphocytosis occurred at one time, but by November last that had disappeared. The temperature fluctuated between 99° and 101° F.

The patient has since died, and the post-mortem examination showed a number of features. There was a marked general tendency to ossification of the tendons. It was not an exostosis, but a definite laying down of new bone. The middle bone of the carpus was found united to the radius, so that the whole structure of the joint was changed. The distal bones of the carpus were united by firm fibrous tissue, and very hard, ivory-like bone was laid down in the interosseous membrane. In the arachnoid membrane 16 sq. cm. of new bone had been laid down. Definite cellular changes were found in the pituitary gland, and there was a great increase in all the absolute measurements of the cadaver. There was a parathyroid tumour the size of a large bean on the under surface; its microscopic structure was very indefinite. The bone-marrow everywhere was white, and there was an aplasia of the red elements and of the leucocyte series. Plasma cells were numerous and were undergoing a chronic inflammatory process. It was a large swelling of the upper part of the right arm which eventually killed the patient; it weighed 23½ lb. Yet there were no metastases, except two doubtful ones in the right lung.

Dr. PARKES WEBER regarded this as an excessive instance of the von Recklinghausen's multiple fibrocystic bone disease.

Tumour of Skull: Jacksonian Epilepsy.

Dr. C. F. T. EAST showed a man, aged 68, with a tumour of the skull. The history was that three years ago he struck his head on a girder and during 18 months he had been having attacks of Jacksonian epilepsy, starting as a flexor spasm of the left foot, and spreading up the left side of the body to the left hand, to the accompaniment of sensory symptoms. Weakness was present in the left hand and leg, with increase of reflexes and an extensor response in the left foot. At the site of the lump on the skull skiagrams showed a rarefaction of bone. The Wassermann was negative.

Mr. E. G. SLESINGER considered that the lump was an endothelioma, and if the man had been in better general condition surgical removal could have been carried out and a flap made.

Cirrhosis of Liver.

Dr. EAST also showed a girl, aged 11, the subject of cirrhosis of the liver. Her Wassermann was now positive, and she was being treated with pot. iod. and mercury. When the girl was 16 months old telangiectases appeared on the face, and since her fifth year she had had two attacks of hæmatemesis and melæna, with frequent epistaxis. The urinary diastase was high. The metacarpal bones on either side were shortened.

The PRESIDENT remarked on the frequent association of nævi with cirrhosis of the liver, and said it was the opinion of some authorities that if a man of 50 developed nævi it was an almost sure indication that he had cirrhosis of the liver, while multiple nævi rendered it a practical certainty.—Dr. WEBER said the angiomata associated with cirrhosis of the liver were, nearly always, "spider nævi." If the finger were placed on the centre of one of these a definite pulsation was discernible, as if it were the site of a softened small artery. The most likely explanation seemed to be the lodgment there of micro-organisms of a low degree of malignancy.—Dr. ATKINSON said he had seen a similar deformity of thumb and large toe in African natives suffering from yaws, a disease much like syphilis, and the process might be analogous in the two diseases.

Osteitis Deformans.

Dr. EAST also exhibited a male patient, aged 58, who suffered from osteitis deformans. Bowing of the legs commenced while the man was in India, four years ago, and since that date his head had been steadily increasing in size, and he had become much shorter of breath when taking exercise. He had had acute rheumatism twice—namely, when he was aged 22 and 34 years. At the present time the skull, the clavicles, the forearms, the femora, and the tibiæ showed the changes typical of osteitis deformans. The heart showed aortic stenosis and some reflux, with marked hypertrophy of the left ventricle. Skiagrams revealed advanced calcification of the arteries of the limbs. The Wassermann reaction was doubtful. The electrocardiogram showed a preponderating hypertrophy of the left ventricle and extrasystoles.

Arthritis and Osteoporosis.

Dr. L. S. T. BURRELL showed an unusual type of arthritis in a woman aged 46, whose fingers and toes had gradually become deformed during the last five years. X rays revealed osteo-arthritic changes in the metacarpal and metatarsal bones. No nerve lesion had been found to account for the condition.

The PRESIDENT commented on the smallness of the affected bones, and thought treatment did not seem hopeful.

A Case for Diagnosis.

Dr. DOUGLAS FIRTH also asked for the views of members on a heart condition in a girl of 10. At first it was considered to be congenital morbus cordis, and she was taken into hospital. The view of a colleague was that it was mitral stenosis. There was no history of rheumatic fever obtainable, nor of tonsillitis or any

infective illness. She was not cyanosed and there was no clubbing of fingers. When she lay recumbent there was audible a short soft systolic murmur and a diastolic noise, the latter, in certain postures, becoming distinctly musical. He regarded the lesion as a congenital one, and thought she could safely lead a normal life. For insurance purposes she did not justify a "loaded" policy.

Dr. JENNER HOSKIN thought the impulse in this case was more heaving in character than normal, that the cause of the musical squeak was exocardial, and that what she had now followed an old pericardial condition. He would ban violent exercises for her, and thought insurance doctors would either refuse her or only approve a loaded policy.—Dr. HALLS DALLY agreed that the lesion was exocardial. The whole precordium tended to heave with the first apex-beat. He did not believe the heart was much enlarged. There was probably some latent rheumatic infection. He discouraged the idea that the child should be regarded as an invalid.—Dr. WEBER said he did not know a definite case in which a definitely musical murmur had been proved to be exo-cardial.

Congenital Morbus Cordis.

Dr. J. L. LIVINGSTONE exhibited a small boy, aged 6, with congenital morbus cordis. There was no history of rheumatism, but three years ago he had diphtheria and the medical attendant detected a heart murmur. He was normal in size and weight according to age, and very alert mentally. There was no cyanosis or clubbing of fingers, but pulsation was marked in the second and third left costal spaces and an accompanying thrill. On auscultation a systolic murmur was evident, not well conducted up the neck, but audible over most of the left side of the chest. The pulmonary second sound was accentuated. The electrocardiogram showed complete heart-block; therefore it seemed there was some lesion in the interventricular septum, interrupting the conduction between auricle and ventricle. The physical signs did not seem to accord with patent ductus arteriosus.

Dr. HOSKIN said there were features in the case against it being pulmonary stenosis. The heart condition was, in his view, a direct sequel of the diphtheria three years ago; the mother was not aware of anything wrong with the heart until the diphtheria illness. The child had a patent interventricular septum.

Syringomyelia of the Cervical Enlargement.

Dr. WEBER showed what he regarded as a typical case of syringomyelia of the cervical enlargement, manifesting the dissociated sensation and other symptoms of that condition. It was most marked in one hand; there was weakness of the other hand. At first sight the man seemed to have acromegaly, but that was chiefly discounted by the fact that there was no fleshy enlargement of parts of the face, such as the nose, the chin, and the tongue. The skiagram did not show any enlargement of the sella turcica.

SECTION OF OPHTHALMOLOGY.

A MEETING of this Section was held on Oct. 8th, when Mr. ERNEST CLARKE, the newly elected President, delivered an address on

OPHTHALMOLOGY IN THE LAST HALF CENTURY.

He had been engaged in ophthalmological work, he said, for 45 years. In 1881 he had attended Donders's Clinic at Utrecht, and there had met Snellen, who had demonstrated his method of detecting malingering by showing red and green letters through red and green glasses. It was nowadays difficult to realise that it was only in 1884 that Koller, of Vienna, introduced cocaine to the profession. Valuable as this was for eye work it was liable to be misused; it was not always realised how valuable an indicator was pain, and efforts were often made to allay it without trying to discover its cause.

Perhaps the greatest change of the last 50 years, said the President, was in the treatment of errors of refraction and muscle-balance. In his early days the refractionist's armamentarium was quite limited, though the shadow test was used. Eye-strain was styled asthenopia, and only one symptom, headache, was attributed to it. The speaker had been inspired to write his book on eye-strain in 1881 by the work of Gould, of Philadelphia. Gradually eye-strain had obtained a fuller recognition, both in ophthalmology and general medicine, so that now it had been established that there was probably no functional nerve trouble in which eye-strain might not be at least a contributory cause. It was possible, by attending to it, to postpone epileptoid attacks, migraine, and recurrent iritis for an indefinite period, and possibly to delay or postpone the appearance of glaucoma and cataract. Eye-strain was more likely to be associated with small errors, and, in sensitive patients, one-eighth of a diopter might make all the difference between efficiency and unfitness. The wastage of effort in eye-strain persisted during waking hours, so that its effect on the nerves was insidious and lowered the resisting power of the individual to infection when he happened to be within its ambit.

Some stated, continued the President, that cycloplegics were not needed when estimating the refraction of an eye, but that was not his view. Most people under 40 years of age could not completely relax their accommodation, so that the doctor could not get down to bed-rock in judging of the real condition of the eye. It was very important to paralyse the accommodation, more especially in all young patients. As, however, the pupil was dilated during the examination a post-cycloplegic examination was often needed before prescribing glasses. As Dr. Hawley, of Chicago, said, the object of the cycloplegic was to ascertain the exact degree of astigmatism. Advance had certainly been made in the period under review in the treatment of myopia. In earlier days it had been customary to allow those with 3 to 4 diopters of myopia to do their near work without glasses. Time had shown that the ideal treatment for myopia was to correct it fully, with any astigmatism which happened to be present; this forced the ciliary muscle to do its proper work, staying in this way the progress of the condition. He agreed with Sir Arthur Keith that myopia was due to a badly constructed sclerotic, and that this was prenatal and inherited. The fault might be due, Mr. Clarke thought, to a defective influence of one or more of the endocrine glands. Presbyopia also was formerly very inadequately treated, a plus glass being prescribed, generally the same for both eyes, and the astigmatism not being corrected, unless it was of considerable degree. The presbyopic age was that at which eye-strain, if present, did most harm, because vital powers were then on the down-grade and recuperation was lessened. He was a strong advocate of bi-focal glasses for this condition, which opticians now made with great skill. The reason some people objected to these was that often the reading portion was made too strong. Great care must also be exerted to secure correct centring of the glasses. In the treatment of imbalance of the extra-ocular muscles Maddox, of Bournemouth, had put the knowledge on a sound basis, and his glass rod test gave an expeditious and easy method of diagnosing heterophoria. A small amount of exophoria or hyperphoria, or both, might cause as much eye-strain as did small degrees of astigmatism, and the two conditions were very often associated. By carefully correcting the refraction the heterophoria could usually be removed. Except in old people, or those whose error was large, prisms were not the best treatment.

Progress in Diagnosis and Treatment.

Dealing with progress in methods of diagnosis and treatment, the President referred to the great value of X rays in ophthalmology, in giving a view of the bones of the skull and indications of abnormalities in association with the pituitary gland, and in giving the localisation of foreign bodies in the eye. Radium, ultra-violet light, and vaccine therapy had

each their value, ultra-violet light being found specially useful in tuberculosis of the iris and ciliary body. In treating many eye diseases it had recently been shown by Hepburn and Browning how important it was to do a differential blood count in sympathetic ophthalmitis. Mr. William Lang, a former president, had continually insisted on the importance of dental sepsis as a prolific cause of eye trouble, and it had been found that similar contributing causes were tonsillitis and disease of accessory sinuses.

Marked changes in the surgery of the eye, the President said, had not been conspicuous in the last 50 years. Elliott's trephine operation for simple chronic glaucoma remained deservedly the most popular. There had been great improvement in the treatment of convergent strabismus in children, but by persuading parents to bring their children for attention at an earlier age a large number of these cases were being cured by glasses alone, and operations for squint being now proportionately fewer than formerly. The surgery of the eye in the unusual conditions produced by the war had been greatly advanced by Sir William Lister and Mr. J. F. Cunningham, and much fighting strength had been conserved by the special precautions instituted to prevent the spread of trachoma, which so seriously affected Eastern races.

Referring to improved education in matters ophthalmological the President recommended that those who had just qualified and had started serving as clinical assistants in an eye hospital should spend at least a year in general practice, if they could do so. This would teach them that the eye was part of the general organism, and not an isolated organ.

Looking to the future, he hoped that the micro-organisms causally associated with trachoma and vernal catarrh would be discovered, and that the true theory of accommodation would be evolved. Much more was yet to be learned as to the significance of blood pressure and the effect of the endocrine glands in health and disease.

Clinical Cases.

Mr. J. F. CUNNINGHAM showed, for Mr. M. S. MAYOU, a case of Massive Detachment of the Retina. At first hæmorrhages had been seen on the surface of the retina at the detachment. At the present time the sites of the hæmorrhages had been replaced by pigment. Mr. Mayou also sent a case of essential shrinking of the conjunctiva, which some thought might be due to pemphigus. Some months ago the boy had an eruption in which the lids were affected.

Dr. HUGH THOMPSON showed a man with the rare condition known as Electric Retinitis, which was, he said, closely akin to eclipse blindness. The stippling in the macula had definitely followed an electric flash, and a fellow worker at the same task had had temporary blindness. The sight of the patient shown, however, had not improved, though the incident had occurred three months ago.

Mr. M. L. HINE showed a man with Neurofibromatosis in the upper lid, with the object of receiving advice as to treatment. There had been pain in the right eye with a persistent discharge which ended in ulceration of the lower lid, owing to the upper lid overhanging it. This right eye was practically blind and useless. His own view was that it was wisest to remove the right eyeball, and provide the patient with an epitheliated socket, as was done in the war.

Mr. TREACHER COLLINS spoke of the procedure adopted in cases of the kind by Mr. Simeon Snell, who removed a large piece of the thick part of the eyelid, with some cosmetic advantage. One patient had had buphthalmos and Mr. Snell had removed the whole eye and sent it to Mr. Collins for pathological examination. He had found that the ciliary nerves were involved, as well as the nerves of the eyelid; the chorioid was thickened, and contained bodies which looked like enlarged nerve end-organs.

Mr. F. JULER spoke of a patient he had shown to the Section five years ago, in which both eyes were affected. At first it was thought that the worse eye was buphthalmic, but afterwards it was concluded that it was only highly myopic, therefore the question of excision had been left in abeyance.

Mr. HUMPHREY NEAME showed a patient suffering from Interstitial Keratitis with Deep Corneal Striation. The deep striation arranged radially occupied three-fourths of the area of the cornea, and was probably due to ridges caused by relaxation of the cornea. The keratitis in this case he regarded as of syphilitic origin. The Wassermann was positive, but the patient showed none of the stigmata of congenital syphilis.

Mr. COLLINS said that he thought that the lines were rucks in Descemet's membrane.

Mr. CUNNINGHAM brought forward a patient with a mass obscuring the optic disc; the case had been originally shown in 1920. There was now a black pigmented area in the region of the disc, and the retinal vessels were obvious. The case came into the category of evulsion of the optic nerve.

Mr. DAVID WILSON (Torquay) showed a man aged 74, who had had detachment of the retina 20 years ago. A few weeks ago, during an illness of asthma and bronchitis, when the patient was coughing, a cataractous lens had been transferred to the anterior chamber. When Mr. Wilson saw him the eye was blind, and the other eye had well-marked striæ and was highly myopic. The first eye was removed. In a somewhat similar case he had been content to remove the cataract.

Dr. RAYNER BATTEN showed on the screen drawings of a series of cases of Tay's chorioiditis.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 64 cases were considered and £785 15*s.* 6*d.* voted to 51 applicants. The following is a summary of some of the cases relieved:—

L.R.C.P. Edin. 1882, aged 73, who practised in the south of England until 1924. Afterwards lived with aged mother until her death last year. Home now broken up. Has been offered a home with a married daughter, but must contribute towards his maintenance. Only income, old age pension. Voted £40 in 12 monthly instalments.

Daughter, aged 64, of M.R.C.S. Eng. who practised in Dorsetshire and died in 1869. Now lives in an almshouse with an allowance of £13 per annum; only other income is a half share in property amounting to £25. Friends gave £2. Maintenance grant asked for and the committee voted £30 in 12 monthly instalments.

Widow, aged 62, of M.R.C.S. who practised in London and died in 1923. Owing to ill-health quite unable to earn her own living and is entirely dependent on her mother, aged 83, whose only income is derived from a small army pension. Voted £30 in 12 monthly instalments.

Widow, aged 59, of M.B. Glasg. who practised in Scotland and died this year. Only income £50 per annum. Has one son aged 22, who is apprenticed to engineering and has two and a half years to serve; he receives one guinea a week, and the applicant has to supplement this to pay his board and lodging. Suitable premises have been secured to enable applicant to set up a tea-shop, and on the strong recommendation of the Fund's visitor a grant was made of £20 in 12 monthly instalments and a special grant of £10 to help furnish the premises.

Widow, aged 33, of M.B. who practised in Scotland and India and died from an accident in April last. Total effects valued at £100. Insurance received £500. Applicant left with two children aged 2 years and 4 months. Now living with relations. Voted £5.

Widow, aged 58, of M.R.C.S. Eng. who practised in London and died suddenly this year. Dependent on two daughters, bank clerks. Only income £14 per annum. Rent of flat taken on lease £125 per annum. Asks for help for boy, aged 15, who has a scholarship at a public school. Voted £10 in two instalments.

Widow, aged 68, of M.D. who practised in London and died in 1919. Has a great difficulty in obtaining work on account of a mentally deficient daughter aged 26, who needs care. They are now dependent on a married son and his wife. Unfortunately the son is out of work and his wife's earnings are their only support. Arrangements are in hand to secure a home for the daughter, and £26 in 12 monthly instalments was voted to the applicant.

Widow, aged 38, of F.R.C.S. Edin. who practised in Middlesex and died last year. When estate is realised there will be an income of about £45 per annum. Applicant asks help with outfit and expenses for only girl who is being sent to school. Voted £20.

Daughter, aged 53, of M.D. Aberd. who practised in London and died in 1880. She lives with a sister in their own house, but owing to neuritis and arthritis has not been able to help in the house and with the boarders as she is accustomed to do. The applicant asked if the Fund would give her a grant towards a holiday, and the committee voted £5 and paid for three weeks in a convalescent home.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos-street, London, W. 1.

Reviews and Notices of Books.

ATLAS OF THE HISTORY OF MEDICINE.

Part I. Anatomy. By Dr. J. G. DE LINT, Lecturer on the History of Medicine at the University of Leiden. With Foreword by CHARLES SINGER. London: H. K. Lewis and Co., Ltd. 1926. Pp. 96. 15*s*.

THE fundamentals of certain sciences are in themselves of a Saharan aridity. The geometrical study of the properties of similar triangles or of the theory of Pythagoras, better known as the Pons Asinorum, is not to most people interesting in itself; but when applied to the measuring of inaccessible heights or distances it is the foundation of many arts and of the solution of varied problems. So with anatomy. The early steps thereof are dull; but when all these dry facts, being mastered, are applied to practical uses, anatomy has an interest of which the beginnings show no sign. Dr. Lint has conceived the happy idea of compiling a pictured history of anatomy, not merely pictures of bones, muscles, nerves, &c., but portraits of anatomists together with reproductions of the title pages of illustrations from their works. Many of the drawings of anatomical preparations are of extreme beauty—e.g., Fig. 114, a skeleton from Bidloo's Anatomy, and Fig. 42, which includes some of Leonardo da Vinci's exquisite sketches. In connexion with the process of injecting vessels with a solidifying injection, as practised by Swammwerdam, Marchetti, and de Graaf, Boyle's name ought to have been mentioned, for he was certainly one of the earliest if not the earliest to practise this method, which he described in 1663 in a treatise "Of the Usefulnesse of Naturall Philosophy." Dr. Singer in his foreword points out that, as is only natural, Dr. Lint has mentioned a great number of his own countrymen and that this stresses the marked connexion between English and Dutch observers in the sixteenth and seventeenth centuries. We are glad to note that Dr. Lint, while he reproduces portraits of Galen and other early anatomists, is careful to label them as "imaginary."

The book is of wide interest and is beautifully got up; we look forward to the appearance of subsequent volumes.

SURGERY OF THE EAR.

Die Chirurgie. A Collective Presentation of General and Special Surgery. Edited by Prof. Dr. M. KIRSCHNER and Prof. Dr. O. NORDMANN. Berlin and Vienna: Urban and Schwarzenberg. 1926. Lieferung 8: Surgery of the Ear. By Prof. Dr. A. BLOHMKE. Pp. 278. M.18. Lieferung 9. Pp. 368. M. 26.

IN this section (Lieferung 8) of Kirschner and Nordmann's large system of surgery devoted to the surgery of the ear, Dr. Blohmke does not deal with diseases of the ear entirely from the surgical standpoint; he mentions affections, such as eczema, otosclerosis, and nerve-deafness, of which the treatment is not surgical, and describes the appropriate medicinal treatment. Nevertheless, the volume is not a text-book of otology, for the non-surgical affections are but scantily discussed, and middle-ear deafness without suppuration receives no mention at all. It would have been better if the author had confined his attention to the surgery of the ear. The book is well and clearly written and shows evidence of having been compiled from Dr. Blohmke's personal experience. He has sound things to say on the participation of the mastoid cells in any acute inflammation of the middle ear, and on the fact that mastoid tenderness during the first few days is not an alarming symptom and certainly not an indication for antrotomy. He is on less firm ground when he objects to the use of glycerine and carbolic drops for the relief of pain on the ground that they veil the drum and delay the perception of the correct moment for paracentesis; they can easily be mopped away during examination, and are invaluable for the relief of pain in many cases of earache which never require paracentesis. In those cases which do require it they help to render the meatus sterile. After antrotomy, Dr. Blohmke considers it necessary to keep the posterior wound open down to the antrum until the middle-ear is dry, and does not approve of any form of complete suture. Antrotomy and radical mastoid operations are well described, as is the chosen operation on the labyrinth, that of Jansen and Neumann. For otogenous meningitis the author considers lavage of the cerebro-spinal cavities of doubtful value and repeated lumbar puncture the only reliable method of treatment after the septic focus has been removed from the ear. The illustrations are sufficiently numerous and very good; there is a short table of contents but no index.

Lieferung 9 of the work deals with the surgery of the abdominal wall, of external hernias, of the peritoneum and omentum, and of the appendix, and the fact that 360 closely printed pages are devoted to these subjects will convey some idea of the exhaustive manner in which they are treated. The volume is well arranged and it is possible in a moment to look up any particular point on which information may be required. The illustrations are excellent.

THE PSYCHOLOGY OF THE THINKER.

By I. B. SAXBY, D.Sc., Lecturer in Education, University College, Cardiff. London: University of London Press, Ltd. 1926. Pp. 355. 7*s*. 6*d*.

THE outstanding characteristic of Dr. Saxby's book is the ingenious combination of the engram theory of Semon, the configuration theory of Koffka, and the dynamic theory of the unconscious of Freud. The first may be regarded as a neuro-psychological fiction which attempts to explain diagrammatically the way in which habits and instinct processes are laid down in the nervous system and the way in which stimuli evoke or activate such processes; the second is a formulation of the psychological process of the formation of wholes out of which experience is made and on the basis of which action is possible; the third is a theory based upon a study of abnormal psychology which attempts to explain the manner in which overt acts and traits of personality are governed by affectively driven systems which lie in the main outside the field of awareness. The author has attempted to show that these affectively driven systems, with the instincts as their nuclei, are themselves to be regarded as configurations in Koffka's sense of highly integrated wholes of which the parts are reciprocally dependent upon one another. These configurations again can be regarded as neurologically engrams or patterns of a complicated reflex order which are activated or ecphored when the appropriate or apparently appropriate stimulus pattern appears. It is difficult at times to discover when the author is referring to an engram and when to a configuration. Such distinction in a complex subject should always be clear. In the first place, engrams are laid down in parts and grow together into patterns as result of neurological repetition along the same or associated paths, whereas configurations are wholes as soon as they appear in experience or are utilised in an act. The distinction, of course, only exists as long as the distinction between body and mind exists, and if the latter distinction is only one of aspect then the terms engram and configuration are themselves terms having the same meaning but expressed in two languages. However this may be, Dr. Saxby has written a readable book illustrated, as every good psychology should be, from all fields of knowledge. Her references range from Köhler on apes, to Trotsky on Lenin, and her illustrations are gleaned from the practical field of education which she has cultivated to good effect; in addition, she has made use of psycho-analysis by the practice of it. Her views upon it are therefore

positive and first hand. The affective life is not alone considered in her book, but the growth of logical thinking is fully dealt with in its relation to the feelings and those unconscious complexes which colour our conscious and apparently logical processes. This brings the author to consider concepts in the light of Vaihinger's theory of fictions, and it is no little tribute to her intellectual honesty that she classes the term engram amongst them.

ST. BARTHOLOMEW'S HOSPITAL REPORTS.

Vol. LIX. 1926. London: John Murray. Pp. 206. 21*s*.

THE fifty-ninth volume of the reports contains ten articles, an obituary notice of Joseph Arderne Ormerod, reports of certain societies and lists of subscribers, prize winners, books added to the library, and so forth. Sir D'Arcy Power contributes an interesting historical survey of the rebuilding of the hospital in the eighteenth century, and Prof. F. R. Fraser reproduces his report to the Rockefeller Foundation on the medical schools of America. On the surgical side Mr. W. Girling Ball reviews 200 consecutive cases of perforated gastric and duodenal ulcer, concluding a masterly analysis with full case records. Sir Thomas Horder has written an absorbing article on Vaquez's disease, dealing more particularly with the complications and giving notes on seven cases. On the pathological side Dr. C. C. Twort discusses some of the problems associated with immunity and the specific therapy of tuberculosis. The other articles in the volume are of a high standard and carefully chosen, and the book is attractively bound.

MEDICAL GYMNASTICS.

Medical Gymnastics and Massage in General Practice. Second edition. By J. ARVEDSON. Translated and edited by MINA L. DOBBIE, M.D., B.Ch., Medical Officer, Chelsea College of Physical Instruction. London: J. and A. Churchill. 1926. Pp. 284. 8*s*. 6*d*.

THE second English edition of Dr. J. Arvedson's book on medical gymnastics has been brought up to date, and should well serve its purpose of making disease intelligible to those who have to carry out treatment in the form of remedial exercises. The practitioner or student of medicine will also find the aims and methods of the Swedish system of gymnastics well set out, and the book will enable him to order treatment suitable to his cases. Certain parts of the text are open to criticism from the strictly scientific point of view; but the volume makes no pretence to be a miniature text-book of medicine and surgery, and it gives a sound enough outline of the conditions important from the point of view of the expert in physical therapy.

JOURNALS.

JOURNAL OF PATHOLOGY AND BACTERIOLOGY. October, 1926.—Foreign particles, the reticulo-endothelial system and anæmia, by A. R. Elvidge (Montreal). Particles of quartz, indian ink, carmine, or trypan blue injected intravenously in rabbits cause the appearance of a large number of nucleated red cells in the circulating blood, and repeated injections give rise to more or less anæmia.—Experimental uric acid nephritis, by J. S. Dunn and C. J. Polson (Manchester). The effect of urates on the kidneys has been the subject of much speculation. It needs large doses to produce any demonstrable effect in rabbits; 0·5 to 1 g. lithium monourate intravenously causes necrosis of the ascending limb of Henle's loop, leaving the convoluted tubules free. This is apparently due to the precipitation of the excreted urate in that part of the tubules. This lesion causes oliguria and lowers the urea-concentrating power of the kidney, and there is considerable increase in blood-urea. This is compatible with the authors' previous suggestion that increase of blood-urea after injury to tubular epithelium is due to abnormal reabsorption of urea along with the normal reabsorption of water.—Further observations on a flocculation reaction for the serum diagnosis of malignant disease, by H. J. B. Fry (London). An extract of breast cancer containing the saline-insoluble, acetone-insoluble, alcohol-soluble substances flocculates with the serum of about 75 per cent. of cases of carcinoma, sarcoma, or lymphadenoma, and with not more than 25 per cent. of cases without malignant disease. Extracts made from rat carcinoma and from normal human pancreas give similar reactions.—The pathogenicity for mice of the normal and rough forms of Gaertner's bacillus, by A. N. Goyle (London.) The normal form is more virulent and more toxic than the rough variant.—Atheroma of the aorta, by J. B. Duguid (Aberdeen). Atheroma is essentially due to impairment of the elasticity and pliability of the intimal tissues, and the actual lesions are caused by the wrinkling of the intima in the diastolic recoil of the vessel. This deformation is especially liable to occur when the artery is held more or less firmly in the surrounding tissues by branches.—The influence of the vasomotor state of the peripheral blood-vessels on the leucocytic content of the blood, by A. F. B. Shaw (Newcastle). The leucocytic content of peripheral arterial blood is not altered by vasomotor changes, but in the veins vasoconstriction leads to an accumulation of leucocytes with a rise in the total without any change in the differential count. This is not due to concentration of the blood.—A case of osteoclastoma (myeloid sarcoma, benign giant-cell tumour) with pulmonary metastasis, by E. F. Finch and H. H. Gleave (Sheffield).—A disease of rabbits characterised by a large mononuclear leucocytosis caused by a hitherto undescribed bacillus, *Bacterium monocytogenes*, by E. G. D. Murray, R. A. Webb, and the late M. B. R. Swann (Cambridge).—The agglutinin content of tissue fluid, by J. S. C. Douglas and F. W. Simson (Sheffield). Tissue fluid is the liquid which is in neither blood-vessels nor lymphatics and which is drawn upon to make up the volume of the blood after hæmorrhage and may be sucked from the tissue spaces into the blood (and so obtained for examination) by the intravenous injection of strong solutions of dextrose or sodium sulphate. The authors show that in both actively and passively immunised animals the tissue fluid contains antibodies (agglutinins), that these can pass through the capillary wall into the blood, and that the endothelium presents a partial barrier.—The influence of the removal of the thyroid, parathyroid, and sexual glands and of thyroid feeding upon the regulation of the body temperature of rabbits, by V. Korenchevsky (London). Thyroidectomy reduces the capacity of the animal to produce heat in response to external cooling so much that young rabbits may die; thyroid feeding restores their reactions to normal. Removal of the sexual glands has a similar but much less marked effect. Parathyroidectomy has no effect.—The influence of optimal proportions of antigen and antibody in the serum precipitation reaction, by H. R. Dean and R. A. Webb (Cambridge). The rate at which particulation occurs in a mixture of horse serum and the corresponding antiserum depends on the relative proportions of the two ingredients. The mixture which precipitates quickest is not the one which ultimately yields the greatest weight of precipitate.—Bacteriological and experimental observations on a case of rat-bite fever, by T. J. Mackie and E. N. McDermott (Edinburgh). *Spirillum minus* was isolated by inoculating enlarged glands into guinea-pigs. Rat-bites are probably infective by the organism appearing in the conjunctivitis which infected animals show and passing down into the mouth.—Identification of the Sonne dysentery bacillus in England, by Hilda A. Channon (London). The Sonne bacillus, originally found in Denmark, has been isolated from a case of diarrhœa at University College Hospital.—Obituary notices of Charlotte Iris Fox, Camillo Golgi, William Boog Leishman, Stewart Stockman, and Meredith Blake Robson Swann.

THE LANCET.

LONDON: SATURDAY, OCTOBER 16, 1926.

WHAT THE SURGEON SEES.

IN his stimulating oration which we print elsewhere in this issue Sir BERKELEY MOYNIHAN reminds us that the surgeon nowadays is something more than the man who cures his individual patients with a direct simplicity which must sometimes move the envy of his brother physician. LISTER opened up a range of possibilities in the way of surgical technique which is perhaps now almost exhausted, at any rate along accepted lines; and until some undreamed-of revolution comes along no great development of the surgeon's manual achievements is to be looked for. What now remains for him to do is to bring his brains into play, to do more for his patient before operation, to study more carefully what happens to him afterwards, and to put all his information together to find out about disease. There was a time when discovery lay mostly with physicians who had leisure to think while surgeons were busy doing things; a surgeon's training was mainly anatomical, a physician's in physiology and pharmacology. But that is now past and gone, and Sir BERKELEY MOYNIHAN urges on those who are embarking on a surgical career that the faith and practice of investigation is as necessary for them as the acquisition of the technique of operation.

All modern surgeons have great opportunities to add to our knowledge of the natural history of disease, and no one has shown more clearly than the Harveian orator himself that they can be used to most excellent purpose. What he has aptly called "the pathology of the living" has completely revised our knowledge of the abdominal viscera. Some of our readers will remember the happy outcome some years ago of Sir BERKELEY MOYNIHAN'S invitation to the sceptical Dr. A. F. HURST to come to Leeds and see in the operating theatre some of the duodenal ulcers of which he so much doubted the existence. Splenectomy is throwing a flood of light on a number of obscure diseases grouped as splenic anæmias, acholuric jaundice, and purpura, and is giving rational explanations for which indeed the hæmatologist and physician had well prepared the ground but could get no further. Our whole knowledge of biliary pathology has been put on a different level of validity, helped by conveniently simultaneous progress by the physiologists, and even in such minor matters as blood transfusion the stimulus has come from the operating theatre. The "pathology of the living" has indeed been fruitful, and we may confidently anticipate a pretty long career of active usefulness before its possibilities come near exhaustion. But if there was at one time a little less sympathy than there should have been between the pathologist in the post-mortem room, who had something safe in a bottle which could be looked at again and again till he was quite sure what he saw, and the surgeon with his vivid accounts of what he had seen hurriedly in a desperate fight with a human emergency, we hope that those who exalt the "pathology of the living" will view more tolerantly the methods and results of the morbid anatomists.

When all is said, the event of death can hardly remove a lesion or alter its essential features. Early or minute foci of disease may be less easily recognisable in the cadaver than in the living patient, largely because of the absence of those disturbances of function which point to their presence; but to admit this is merely to admit the necessity for the more accurate and careful practice of naked eye and microscopic morbid anatomy. The blind worship of the bottled specimen is as dead as Druidism; modern morbid anatomy is not the study of pathological specimens but of pathological processes. The attitude of the modern pathologist is essentially dynamic. He knows, and to do him justice usually teaches, that each of his specimens has a past as it would have had a future had not death or the surgeon's knife intervened. He deals with lesions which have been arrested, and it is his business to know not only the processes which have led up to the particular stage of the disease he is studying, but also the developments which might be expected to occur. Sir BERKELEY MOYNIHAN, of course, makes no suggestion that autopsies can no longer be expected to tell us very much, but the less thoughtful admirers of his methods sometimes decry the older teachings. A first-rate new road does not necessarily make the old road useless, and morbid anatomy still has its discoveries to report, and fresh ones yet to make. There are many roads to the understanding of disease; what is needed is that they should all meet.

THE HEALTH EDUCATION OF THE PUBLIC.

THE aims which ought to be before those who consider that the medical profession has a mission to educate the public on health questions through the lay press, as well as the methods advisable for carrying out those aims, were the subject of a lucid address by Sir THOMAS HORDER on Tuesday last, the occasion being a meeting of the St. Pancras Division of the British Medical Association. Save for a few preliminary remarks we publish the address in full, for though the subject has been much discussed, and may seem to some to have been over-discussed already, it remains one of great interest to the medical profession at large, while frequent debate has led to no practical result. And if we are to be guided by the curiosity that has been manifested in many quarters as to what Sir THOMAS HORDER was going to say, the public is as much interested as the medical profession. That curiosity will undoubtedly be disappointed in certain respects, for the speaker made no fiery attacks upon individuals and abused no authorities or associations. He acknowledged the good that might be done through the medium of publicity, while indicating the forms of publicity that were inadvisable, either because the teaching could not be adequate, or because the motive for publishing it might be mistaken. All true; all often said; but none the less worth saying again in Sir THOMAS HORDER'S convincing manner, lest the fundamental facts should still escape our minds.

It would be unnecessary to inform a medical audience that public instruction on health matters is desirable, if it were not for those who cannot bend the proud professional neck to meet the least relaxation of rules of behaviour instituted in days when any lay public to whom appeal was made formed necessarily a completely uninformed audience. For sticklers Sir THOMAS HORDER had the practical intimation ready "that the public has decided that it wants health talk and means to get it." And at this point he made a classification of the forms of public instruc-

tion, either in respect of general health or in respect of personal hygiene; and this should be of assistance to medical men needing guidance on the ethical side. After a caustic analysis of the kind of medical article which the public seems to want (which must be the kind of medical article which certain journals intend to give), he drew a distinction between "information" and "instruction" which may well be borne in mind by those who consider it their duty to sign hygienic messages in the lay press. Far greater latitude, he explained, could be allowed to those who are "telling the story" of a disease—i.e., who are giving general information about that disease—than to those who propose to instruct the public upon its treatment. He was following in spirit here the classification implied by the General Medical Council when dealing with the subject of advertisement in the Warning Notice issued to the profession; this Notice categorises the actions commission of which may come in for unfavourable censure, and "telling the story" would entail no professional risk on the narrator. But it is well to remember that even such narratives with the signature of a doctor attached, may be open to objection. The information on medical questions regularly disseminated to the public from the Ministry of Health will serve as a pattern for the kind of article the publication of which in the lay press is all for good, but the issue of pamphlets from a State bureau should not be regarded as forming a precedent for the action of any individual medical man who desires to write signed medical articles of an informative nature. The very publicity which redounds to the credit of a bureau or an association may damage the reputation of any doctor.

All Sir THOMAS HORDER'S skill in putting forward his arguments failed to disguise the fact that, certainly through no fault of his, the subject is left very much where it was. The sort of signed medical article which is quite undesirable and which is stigmatised as such by the General Medical Council, was condemned—at any rate by implication, and the article which everyone knows to be blameless, and which often must be useful, was acknowledged as such. But who is to adjudicate on the articles which fall between the two extremes; who is here to appraise when it is obvious that the powers of the General Medical Council cannot be invoked? And what is to be the penalty? And how is it to be enforced? A resolution was passed by the meeting, suggesting the formation of a control committee to help lay editors to estimate the worth of medical contributions to their columns. Undoubtedly such a body might be of real use, but the difficult task remains of setting it up in such a form, and with such a composition, that editors of lay papers would respect its views. The Federation of Medical and Allied Services, as Sir THOMAS HORDER suggested, may have here an opportunity for constructive work, of value alike to the public and the medical profession.

OUR KNOWLEDGE OF APHASIA.

Dr. HENRY HEAD has published in two large volumes,[1] amounting to nearly 1000 pages, a complete exposition of those views of his on the problem of aphasia with which the profession has to some extent already been familiarised through the medium of various communications in journals. The first volume contains a historical retrospect of some 140 pages, a vastly interesting section, which begins with some account of the work of the phrenologist GALL and passes in review various stages in the development of our knowledge of aphasia by summarising, sometimes at length, the contributions associated with the names of BOUILLAUD, BROCA, HUGHLINGS JACKSON, PIERRE MARIE, HENSCHEN, VON MONAKOW, and others. This historical section is frankly selective, none the less, in the sense that it deals almost entirely with such views as in the author's opinion indicate acceptance of that general approach to the subject which he himself adopts—the psychological approach. Dr. HEAD admits with openness that he has decided in this section to ignore previous contributions which have no direct bearing on his own observations and with which he is in complete disagreement. Thus there is little or no attempt at comprehensive criticism, which for that matter would doubtless be out of place; certain of the tenets of the late Dr. CHARLTON BASTIAN are dismissed as "disastrous"; HENSCHEN'S method inevitably suffers from "grave defects," but no serious effort is made, as not being felt to be necessary, to deal seriatim with previous hypotheses. In the author's words: "Round and round like a stage army moves the procession; the clinical appearances are identical, but each fresh group of observers views them with new eyes and with different preconceptions."

Dr. HEAD'S theories are based largely if not entirely on the results of his examinations of clinical cases, examinations carried out according to a scheme of his own, full details of which are furnished the reader. For this scheme is claimed novelty and originality: it certainly contains both elements. In addition to some more or less usual forms of clinical investigation there has been elaborated a long series of tests of a somewhat different kind, embodying plans for detecting behaviouristic reactions to stimuli by various sense avenues. Speech, according to Dr. HEAD, is behaviour, and it is legitimate to test behaviour along lines that have seemingly no direct connexion with speaking, reading, or writing. Not a little, therefore, of the manner and matter of these ingenious tests will appear to the neurologist to be outside the realm of speech altogether, as commonly understood; and the same is true of other tests supplementary to the scheme itself. It is difficult to comprehend how a game at billiards, or throwing paper balls into a concealed basket, or setting a breakfast table, or threading a quadrilateral frame for a beehive, can be raked in as varieties of the psychological function which men call speech, but Dr. HEAD is in no way perturbed at the idea. He does not accept, and is, indeed, very critical of, the usage of the terms agnosia and apraxia in respect of disorders such as he himself classes with aphasia; he considers they are on a *lower* psychological level than those of speech and have little to contribute to his theory. This is set forth towards the end of his descriptions of the clinical manifestations he has been studying, and is to the following effect: disorders of language are disorders of "symbolic formulation and expression." This definition the author is at once careful to qualify, in the sense that it is not to be thought to define the limits of speech defect. "Any form of mental behaviour is liable to suffer which demands perfect reproduction and use of any symbol between its initiation and its fulfilment." Evidently, then, Dr. HEAD has immeasurably widened the ordinary conception of speech, and in so doing declares it is not possible to "include within one categorical definition all those activities which experience shows to be affected." The reader at this point will naturally ask what is signified by "symbolic formulation and expression," and the answer is: "a mode of behaviour in which some verbal or other symbol plays a part between the initiation and execution of the act." In another place the author states that these disorders of behaviour "extend on the one hand from mechanical aptitudes to exercises in formal logic on the other." We are doubtful whether an all-embracing conception of this kind will have that clarifying action on the

[1] Aphasia and Kindred Disorders of Speech. By Henry Head, M.D., LL.D., F.R.S., consulting physician to the London Hospital; honorary fellow of Trinity College, Cambridge. In two volumes. Cambridge: University Press. 1926. Pp. 549 and 430. £3 3s.

problem which its author earnestly desiderates. It must by definition include numerous intellectual procedures resulting outwardly in behaviour such as no one who believes in common sense can consider speech behaviour, while within its generous scope the functions of speech as ordinarily understood are surrounded by a host of other intellectual functions and are in danger of losing their individuality. Dr. HEAD endeavours to simplify current ideas on speech, not so much by considering it as part of a larger psychological function as by adding to it many intellectual activities that have hitherto been judged to belong to a non-speech psychical series.

From the most painstaking examinations of some 23 clinical cases (the details of which are recorded at length in the second volume), based on his own scheme, the author comes to the conclusion that four varieties of speech disorder can be usefully differentiated; these are denominated by him verbal, syntactical, nominal, and semantic aphasias respectively. While in the case of each of these a more or less outstanding clinical feature justifies its being utilised to describe the form taken by the group to which it belongs, the author makes it clear that he neither regards his types as clean-cut entities nor wishes it to be imagined that functions are disordered in any particular one which escape in the others. The terms he employs are indicative, but not definitive. He does not accept any localisation of the function of speech, an intellectual function; it is perhaps therefore a rather unexpected concession to localisationists that Dr. HEAD has set himself the arduous task of endeavouring to ascertain from the site of the scalp and cranial wounds of his war cases (which form his clinical material almost in toto) what portion of the cerebral cortex has been injured. This is the least impressive section of a monumental contribution; the method employed is open to obvious neuropathological objections, and the statements made will in some respects scarcely stand investigation. It is claimed, for instance, that in gunshot wounds of the head the effects of the injury tend to spread themselves over the cortex, and that in civilian cases most of the lesions resulting in aphasia are subcortical, and the contention is made that war wound cases present great advantages over civilian cases—a view which has already been adversely criticised by more than one contributor to the problem of aphasia. Towards the end of his first volume the author remarks that "no criticism of my results is valid unless the patient's condition has been explored by similar or more perfect and extensive methods." Dr. HEAD is so conscientious a worker and so minute an observer that there is no thought of questioning his results; on the contrary, if war wound cases are examined by Dr. HEAD'S technique the results will doubtless be the same. The points at issue will consist less in the class of data extracted from clinical examinations of a particular type of material by a particular scheme than in the nature of that scheme, in the interpretation of the data, and in the hypotheses based thereon. He has set a high standard of testing psychological function, and incidentally has amply justified his objection to much that has hitherto been recorded in the literature of aphasia—the investigations have been woefully fragmentary and incomplete. He has proved the necessity of using graduated tests, and has explained and justified his argument that such terms as alexia, agraphia, and so forth are too absolute; they fail to take into account the variability of the symptoms in the average case. Undoubtedly misused in the past, the clinician will have to be more discriminating in his use of them in the future, even though he should be unwilling, pace Dr. HEAD, to throw them into the discard.

No one who patiently peruses these volumes can lay them down without feeling deeply impressed both by the author's erudition and his infinite attention to detail. No such elaborate monograph on aphasia has ever been published in English before. While it contains an unusual amount of repetition and reiteration (quite apart from useful summaries provided at appropriate intervals), it is provocative of thought and disturbing to preconceptions, and herein, we think, lies part at least of its value. Dr. HEAD with disarming candour declares that the results he has obtained "are of little direct practical value to the physician," and in one place there is evidence of a feeling of regret on the author's part that cases of aphasia are seen by the neurologist when it is really the psychologist who should come under their fascination and utilise them for the study of the interaction of body and mind. This is doubtless because his own approach is from the latter's standpoint; believing, as he does, that physiological and anatomical considerations are altogether secondary, he naturally develops them very little. Whether such descent on the problem from above, so to speak, is preferable to ascent from below, is perhaps beside the point; yet it would be unwise to belittle the contribution of the neurologist. The lesson *he* has to learn is that the study of the mind in disease will not be facilitated by neglecting the complexity of the problem.

THE FREEDOM OF MEDICINE.

Dr. C. O. Hawthorne, in delivering the introductory address to the students at the Durham University College of Medicine, Newcastle-on-Tyne, on Oct. 8th, dwelt especially on the influence which the atmosphere of a university life should have in the cultivation of independent judgments and the development of personal views. The university should provide, he said, such a measure of freedom, tempered with such a degree of discipline, that those who submitted themselves to the training were fitted for the larger opportunities and the display of individualism in practical life, with its corresponding burdens and responsibilities. He claimed for the profession of medicine that it supplied just such an atmosphere, one in which a man's work would give him the opportunity to display that initiative in judgment and that self-control which are the two great benefits offered by university education. The argument for a university training for medical men could hardly be better put, for in medicine the individual opinion and the individual action are neither enforced on the one hand nor restrained on the other by an arbitrary or quasi-infallible authority. This was not so in the past either in medicine or in any branch of human wisdom, but medicine is alike so rapidly developing and so widely finding affinities between itself and associated sciences that in medicine response to central authority cannot be made into a mechanical affair. The university training is sure to inculcate sufficient respect for tradition, but Dr. Hawthorne's message to the Durham students, that it should also supply the qualities necessary for arriving at independent judgments is not commonly recognised. As a matter of fact, all medical training in this country is to-day of university pattern to a large extent—that is to say, the modern medical school is no longer a one-sided technical training institute. The curriculum, it is true, after the preliminary stages, has no further connexion, and does not mention, what used to be called literæ humaniores, but the modern medical student will find that appreciation of literature is apposite to his work, while in its various special branches that work is in distinct relation with such other university faculties as natural philosophy, mathematics, law, and even divinity.

GUILD OF ST. LUKE ANNUAL FESTIVAL.—This year the annual service of the Guild will be held at Westminster Abbey on Sunday, Oct. 17th (the eve of St. Luke), at 6.30 P.M., when Canon Sopwith will be the preacher. A limited number of seats will be reserved for members of the Guild, but it is hoped that other members of the medical profession will also attend. Members who desire to robe are invited to assemble in the Jerusalem Chamber not later than 6.15 P.M. Holders of tickets should enter the Abbey by the West Cloisters' door through Dean's Yard. The annual corporate union of the Guild will be celebrated at the Grosvenor Chapel, South Audley-street, at 8.15 on the morning of St. Luke's day. The annual chapter will be at King's College, Strand, at 5 P.M. on the same day.

Annotations.

"Ne quid nimis."

THE RELATION BETWEEN CANCER AND TUBERCULOSIS.

THERE has been some talk, not all of it loose, of an antagonism between cancer and tubercle. A recent inquiry [1] at the Harvard Department of Pathology brought to light only 18 cases of concurrent malignant and tuberculous disease of the female breast, but the authors themselves regard the rarity as sufficiently explained by the different age-incidence of the two diseases. Delbet and Monod [2] initiated a more general discussion of a possible antagonism several years ago, and Dr. T. Cherry, of Melbourne, drew attention recently in our own columns [3] to a possible relation between the steady decline in the number of deaths from tubercle and the equally steady advance of cancer, the two rates being now about equal in England and Wales. He recalled an observation made by Mr. W. R. Williams [4] that when several members of a family had died of phthisis the survivors were very apt to develop cancer and suggested the need for further inquiry. The views of a number of continental authors are summarised in an interesting paper by Dr. G. Ichok, [5] who reaches no conclusion except a warning to the clinician not to forget the possible concurrence of the two diseases. In a recent Italian publication [6] the inquiry has been taken up by Dr. Pasquale Corsonello, of the University of Naples, who recalls the fact that Rokitansky had himself worked on this problem. He describes in detail two cases in which pulmonary tuberculosis was implanted on the cachectic state of cancerous patients. One was a man, aged 42, with a pyloric cancer the size of a large orange and marked signs of phthisis at the right apex with Koch's bacillus in the sputum. The other a man of 46 with a stenosing cancer of the œsophagus and tuberculous infiltration of both apices. The great facility with which cancerous tissue destined to rapid degeneration can be invaded by organisms from the surface or cavities is well known. Menetrier observed that Koch's bacillus may also be met with in such conditions, having gained access through the ulcerated surface or through the lymphatics, and previously latent in the organism. Prof. Corsonello relates two cases which demonstrate this. One a woman, aged 45, with an ulcerating mammary carcinoma the size of a fœtal head. Examination of the exuding pus revealed the usual pyogenic organisms, but Koch's bacillus was not found until a much later date when the patient had been in contact with a daughter who had developed pulmonary tuberculosis with the specific bacillus in the sputum. The second case was a youth, aged 18, suffering from an apical tuberculosis. A tumour of the nature of an osteosarcoma of the iliac bone made its appearance, which two months later softened and tuberculous pus was evacuated. The tumour continued to grow and eventually caused death. The explanation seems to be that the tubercle bacilli found their way via the lymphatics from the lung to the neighbourhood of the neoplastic tissue on which they expended their action as a "locus minoris resistentiæ." Showing that a generalised tuberculosis may arise from the local infection of a malignant tumour, Dr. Corsonello quotes the case of a woman, aged 48, who had suffered for a year from a mammary schirrus with axillary metastasis. The tumour ulcerated and Koch's bacillus was found in the discharge. A month later signs of pulmonary tuberculosis showed themselves, the lungs having been previously healthy as ascertained by radiography. Menetrier considers that neoplasms result from a peculiar evolution of the tissue cells which they acquire as a sequence of a kind of morbid education of "pathological selection"; chronic inflammations, especially tuberculous, are capable of producing this epithelial metaplasia which is the characteristic of the cancerous process. Apart from any criticism of Menetrier's theory, it seems that Dr. Corsonello's cases show that there may be some association between the two processes, tuberculous and cancerous.

HEALTH IN THE MERCANTILE MARINE.

Two years ago the Royal Sanitary Institute suggested to the Board of Trade that the classification employed in the Board's report on Deaths of Seamen was out of date and should be remodelled in the light of modern knowledge. The Institute went on to express the view that the compilation of death statistics and the care of the health of men in the merchant service should be given in charge of the Ministry of Health, the Board of Trade not being specially organised for this duty. Similar views have been expressed in our own columns. The pamphlet just issued [1] tells us that, moved by these criticisms, the Board of Trade asked the advice of the Permanent Consultative Committee on Official Statistics, which in its turn referred the matter to a subcommittee of statisticians with a request to examine the statistical basis of the return of deaths, to decide whether death-rates of value could be calculated from it, and whether its classification should be altered. The subcommittee was commissioned further to examine the figures of occupational mortality in seamen given in the Registrar-General's decennial report on the Census, and to consider the propriety of issuing an annual statistical report on the health of the mercantile marine. The pamphlet is the report of this subcommittee, which has been adopted by the Permanent Consultative Committee, Briefly stated, the decisions reached are that criticisms of the return because it does not include death-rates are ill-founded, for the population concerned is too fluctuating and the causes of death too inaccurately reported; that the return should continue to be published, but that the Registrar-General should advise the Board as to the changes necessitated by the inaccuracy of the data, that the Registrar-General should allow both for the seamen "on articles" (i.e., employed) and for those on shore in discussing the occupational mortality of their class; and, finally, that a statistical annual report on the health of the mercantile marine analogous to those of the Army and Navy is impossible, the data being too limited. The report shows how carefully the question has been studied within the limits imposed by the terms of reference, and how difficult it is to decide from the information now available how many British seamen there are in any year, and precisely how many of them died. The present return estimates the number of British, foreign, and lascar seamen and the number of deaths of men "on ships' articles" for the same groups, but when seamen die ashore, as many do, the records do not always distinguish between death of British seamen on British ships or British seamen on foreign ships, or allow for men from the Irish Free State whose sailors are unenumerated. Even the National Health Insurance records of seamen are too little continuous to be of help. No reply has yet been made to the second resolution of the Institute. It seems that because we cannot get a meticulously accurate death-rate for merchant seamen we are to have none at all, but even whole numbers may be informing. The Board's return for 1914 showed that in the preceding 12 years the death-rate of seamen from disease had fallen from 4·8 to 3·4, from accidents, &c., in sail from 18 to 14·6, in steam from 5·9 to 4·3. But statistics are not everything. The Board has a list of all the

[1] Statistics Relating to Health and Mortality in the Mercantile Marine. Report of the Subcommittee of the Permanent Consultative Committee on Official Statistics. London: H.M. Stationery Office. 1926. Pp. 12. 4*d*.

deaths occurring on merchant ships in any year. Has it no medical officer to whom to refer it for criticism and advice with a view to prevention, and why should not that list go over to the Ministry of Health for expert examination and report by a staff skilled in the understanding of medical facts and implications?

MOULDS.

A GREAT deal of work is needed before the identification of moulds will be carried to the bacteriological precision which dissects the salmonellas and types the pneumococci. When a pathologist comes across a mould, he is generally content enough if he can say whether it is an aspergillus or a penicillium; there is no very readily available literature which will help him into any details which his curiosity may ask for. A book written by two members of the staff of the Microbiological Laboratory of the United States Department of Agriculture may therefore fill a useful place.[1] The greater part of the book is descriptive and systematic, and this section represents well the determination of the Americans to give expression to their appreciation of the great truth that sound systematics is the only sure foundation of experimental biology. There is, however, also a general introduction which summarises what is known of the physiology and pathology of aspergilli. They are used in a variety of domestic and commercial industries—to ferment soy beans and fish in the East, to improve the flavour of coffee, to make citric acid—and are well known as the cause of a fatal disease of the air-sacs in birds, in a somewhat dubious relation to inflammations of the meatus and other parts of the skin in man, and as gaining a lodgment in diseased lungs. If the obscurities of most of their pathology are to be cleared up, an accurate identification of species is the first necessity; towards this the book should be of real value.

RESPIRATORY VARIATION OF THE PULSE.

IN his classical work on the cardiac arrhythmias Mackenzie differentiated between those forms of irregular pulse which are, and those forms which are not, of serious prognostic significance. He pointed out that almost constantly in healthy children and not uncommonly in young adults the pulse frequency tends to vary with the phases of respiration, increasing during inspiration and decreasing during expiration. In addition to this juvenile type of irregularity, as Mackenzie called it, another form of sinus arrhythmia is occasionally met with in which the pulse-rate waxes and wanes in a perfectly regular fashion, but independently of respiration. In both these conditions the pulse is of smaller volume during the rapid than during the slow phase. A more extreme rhythmic type of variation in pulse amplitude, known as the pulsus paradoxus, occurs in association with chronic mediastinitis and is there probably attributable to direct compression of the subclavian artery by traction of the surrounding tissues during inspiration. The variation in heart-rate associated with respiration is generally attributed to alterations in vagal tone, and provided the minute-volume of the heart remains constant the output per beat will vary inversely with the pulse-rate. There is, however, a second factor which comes into play, for the negative intrathoracic pressure during inspiration tends to dilate the pulmonary vessels and so to accelerate the blood flow through the lungs. Hence the venous filling of the left auricle is increased and this leads to a corresponding increase in the output of the left ventricle. The immediate result of dilatation of the pulmonary vessels, however, is to enable them to accommodate a larger quantity of blood; so there is an appreciable lag between the commencement of inspiration and the augmentation in the systemic output. In a recent paper in the *American Journal of Physiology* Prof. R. T. Barry has called attention to the fact that, in estimating the systolic blood pressure in man by the auscultatory method, the phases of respiration have to be taken into account, for with a given compressing pressure in the armlet the pulse-beat may produce sound during one phase of the respiratory cycle whilst during the other phase it may fail to do so. Similarly in those rarer cases, to which we have referred above, where there is a slow but rhythmic variation in pulse frequency extending over a series of respiratory cycles, during the phase of more rapid heart action the Korotkow sounds may cease to be audible. This is an interesting observation from the physiological standpoint, but clinically it is of little significance, for a variation in systolic pressure of less than 10 mm. is for practical purposes negligible in the diagnosis and treatment of disease, and a rhythmic variation greater than this is not likely to be attributable to respiratory factors except in those conditions which give rise to the pulsus paradoxus.

TESTS FOR COLOUR VISION.

INGENIOUS devices for testing colour vision are always of interest. The well-known principle of Stilling's pseudo-isochromatic cards, of which a new edition has just been issued,[1] is that the dichromic will be unable to decipher figures composed of red dots on a background of green dots, and similarly other pairs of complementary colours. Various shades are used, and in this edition cards are included which are meant to demonstrate a diminished blue-yellow sensitivity and diminished sensibility for violet. One card is constructed in which those alone who have a heightened sensitiveness for colour contrast and variations in brightness can make out any figures, and some charts are added for the detection of malingerers. The construction of these cards is based on the trichromic theory of colour vision. Some years ago Edridge-Green published somewhat similar ones illustrating his own theory, and these were designed to detect all degrees of colour defect. The chief advantage of cards of this description is the ease and rapidity with which they can be used. For accurate testing in difficult cases it is generally admitted that the use of spectral colours by means of a lantern is the best test.

Another set[2] of cards has reached us on which are painted oblongs or dots which to the normal eye in daylight all look alike—grey. They are described as "Umschlagfarben," this term being used to indicate combinations of colour which appear alike to the normal eye by daylight but by artificial light seem decidedly different, some spots appearing more red, others more green. The subject of partial colour blindness, on account of his greater sensitiveness to either red or green, as the case may be, is able to recognise by daylight these differences of colour which are apparent to the normal sighted only by artificial light. The cards are made on the same principle as the Stilling ones, but constitute a more delicate test which can only be employed in special conditions of daylight. The technical difficulties in the reproduction of the colours took two and a half years to overcome. It is claimed that the test is a quantitative one, able to detect not only the presence but different degrees of colour defect and, therefore, of practical use not only to the ophthalmologist but also to those technical industries where good colour vision is of importance. It seems unlikely that under the climatic conditions of Great Britain the method could be widely adopted with success unless an artificial daylight installation was also provided.

SEMINAL VESICULITIS.

AN infected seminal vesicle can, as Mr. Frank Kidd has shown, remain blocked and full of the infecting agent for many years, and in an article which appeared in THE LANCET last week on the surgical management of seminal vesiculitis from the pen of the late Dr. A. Reith Fraser, lecturer in venereal diseases at the University of Cape Town, and Mr. L. B. Goldschmidt, surgeon to the New Somerset Hospital, Cape Town, it was pointed out that no part of the urogenital system suffers so much from neglect as do the seminal vesicles. These authors pass under review the various methods of treatment which have been tried in the acute stage and after the infection has become chronic, and they give the results of their own very large experience of such methods at Cape Town. Their conclusions are noteworthy in maintaining an admirably balanced judgment. Whilst relying on methodical vesicular massage as the sheet anchor of treatment, they admit the value of adjuncts to this treatment, and especially the value, in rebellious cases, of vasostomy, devised by Prof. W. T. Belfield, of Chicago, and substantially improved[1] by Mr. Kidd three years ago. For washing out the vesicles they found effective a 25 per cent. solution of argyrol; its use shortened the average length of treatment by three-quarters and often converted a case which was not responding to conservative measures into one that responded. Only when vasostomy fails, but not before, is the severer operation of vesiculectomy in place. Dr. Fraser and Mr. Goldschmidt's paper, although it records no new methods of treatment, deserves careful study from all who have to do with urogenital disease, for it codifies the therapeutic armoury of vesiculitis and appraises the exact value of the several weapons which it contains. Dr. A. L. Wolbarst, of New York, has also called attention recently [2] to the singular neglect by American surgeons of the not infrequent infection of prostate and vesiculæ by the colon bacillus, due, he believes, to chronic intestinal auto-intoxication. He also has found favourable results to follow vesicular irrigation by means of Belfield's operation.

MALIGNANT MYELOID SARCOMA (OSTEOCLASTOMA).

THE ordinary myeloid sarcoma of long bones is justly regarded as the most certain example known in human pathology of a tumour which has the local invasive character of a malignant growth, while it may be trusted not to disseminate and may be safely treated by local removal. A case recorded by Mr. E. F. Finch and Dr. H. H. Gleave, of Sheffield, in the current number of the *Journal of Pathology and Bacteriology* (reviewed on another page), reminds us that this tumour does not always keep to these rules. The case has a peculiarly instructive history. A man of 49 slipped on ice in 1917 and fractured the lower third of his right femur; good apposition could not be obtained and at operation the bone was found to be very soft, which was supposed to be due to osteitis deformans. The fracture healed and, except for some pain and swelling 18 months afterwards, the man went on fairly well till 1921, when he came back to hospital with a swelling above his right knee. The radiologist reported myeloid sarcoma and a re-examination of the 1917 skiagrams showed evidence of a medullary tumour which had been overlooked. The tumour was now too large for local removal to leave a useful leg and amputation was undesirable. But at the end of 1924 he was disabled by a spontaneous fracture and the leg was taken off in January, 1925, eight years after the patient was first seen and ten years after the first symptoms of "rheumatism" in the right knee. In October, 1925, he returned with a painful swelling in the stump and spitting blood-stained sputum, and died in January, 1926. Post mortem there was extensive recurrence in the stump, a number of secondary growths in the lungs, but no metastases elsewhere. Histologically, the primary growth, the recurrence, and the secondary nodules all showed the typical characteristics of giant-celled myeloid sarcoma. The clear account given by the authors requires no comment. But we may note with approval their proposal that the terms "myeloid sarcoma" "myeloma," and "benign giant-cell tumour" should be dropped in favour of "osteoclastoma," a title which is less liable to confusion and which adequately summarises the view that these growths are essentially polymorphous-celled sarcomas which differentiate on the one hand into fibroblastic tissue and on the other into giant cells analogous to osteoclasts—the two elements which in various proportions make up the developed tumour.

TOBACCO AMBLYOPIA.

WE may have to delete from the list of ailments due to tobacco one in which the specific effect of nicotine has hitherto been almost undisputed—namely, tobacco amplyopia. Dr. Léopold Bussy, in a recent issue of the *Journal de Médecine de Lyon*, makes out a case for the supposition that there is no such thing as true tobacco amblyopia. He holds that nicotine, like other toxins, may play a minor part, but that toxic retrobulbar neuritis is practically always due to the abuse of alcohol. His description of the clinical picture agrees with that of Osler: the lesion is bilateral and shows itself in a loss of capacity to distinguish first red and then green, and in a blurring of objects at the point of focus; the peripheral vision remains unimpaired. The condition appears to be on the increase in France and to affect every class impartially. Dr. Bussy suggests that its growing frequency may be due to the redistribution of wealth which has taken place since the war and which has afforded an opportunity for over-indulgence in alcohol to persons who were obliged previously to observe moderation. He bases his argument on a study of the literature, in which he notes that the ætiological factor indicted is practically always alcohol and very often both alcohol and tobacco, but rarely if ever tobacco alone. Even when tobacco seems to be the chief culprit there is nearly always another toxic factor present, such as syphilis or a septic focus. The fallacy, he says, originates in an ancient traditional superstition. The type of the smoker-and-drinker has invaded the popular mind in a number of classical symbols such as the wastrel of the realistic novel-writer, the degenerate who, with a cigarette-stub depending from his lower lip, "supports" a bar and swallows drink after drink until closing time; the campaigner with his pipe and pot, the sailor with his twist and tot, and Dutch paintings of tavern interiors with village worthies smoking long clay pipes and drinking beer out of highly decorated steins. Clinicians have been unable to free themselves from this obsession and have fallen into the error of allotting equal rôles to both drugs, or they may possibly (but this is a point which Dr. Bussy does not make) inherit a tendency to suspect tobacco from their ancestors of 200 years ago, who were used to drink but to whom smoking was a vicious innovation. He holds English text-books almost entirely responsible for the perpetuation of this fiction, and recounts the quaint experience which first led him to suspect it in 1918. An army captain, whose ailment an English specialist had diagnosed as tobacco amblyopia, and whom he discharged after 21 days' treatment, left 22 large empty Benedictine bottles in his room, and this evidence suggested to Dr. Bussy that "alcohol" should be substituted for "tobacco" not only on the officer's clinical record but also in the standard works. It is certainly significant that there is no more amblyopia among workers in tobacco factories than there is in any other industry. Apart from his rejection of tobacco from the ætiology, however, the author also plays havoc with accepted ideas on the pathology of the lesion. If it were simply due to an inflammation of the interstitial tissue, neuroglia and

septa of the optic nerve, leading to strangulation and atrophy of the nerve-fibres, there is no sound reason why it should select the macula for its manifestations rather than any other part. Again, no damage to the vascular system of the optic nerve could explain it, for the connexion between these vessels and the macula is not at all an intimate one. If, however, we admit with Nuel that the primary lesion is in the ganglion cells of the macula and paramacula—that is to say, in the retina at the point of focus—the disease takes its place logically with scintillating scotomata and central amblyopias due to male fern or quinine. Its apparent selectivity is due to the fact that the toxin renders the cells of the ganglia capable of being decomposed by light, and the centre, where most of the light is concentrated, is the first to go blind. Many patients only complain of visual impairment after an exposure to strong light, such as the glare of a road or a snow-slope on a blazing summer day. A photographer will blame his flashlight and an electrician his bulbs. This would explain the restriction of the damage to the central spot. The author suggests that he has shown sufficient reason why the nebulous term retrobulbar neuritis should be replaced by "alcoholic macular retinitis." His paper throws down a challenge of some importance to his fellow ophthalmologists.

A LAYMAN'S INDICTMENT OF DICHOTOMY.

THE system of secret fee-splitting between physician and surgeon was never likely to be approved by the lay public. Outspoken criticisms of it appear in an article entitled A Layman's Fears, published in a recent number of the *Madras Medical College Magazine*. The author, Mr. Govinda Krishna Chettur, principal of the Government College at Mangalore, has some flattering things to say of the medical profession, but he cannot conceal certain uncomfortable misgivings and his criticisms of dichotomy are only one part of a larger indictment. He is not concerned, he explains, over "those amiable gentlemen who—for a consideration—have not the heart to deny the necessitous individual a certificate of health or disease, as the case may be," but he feels that both physicians and surgeons are allowed a dangerous freedom from control. Someone falls ill, says Mr. Chettur, appendicitis or some similar trouble is diagnosed, and an operation is spoken of as essential. The operation takes place with one of three results—the patient recovers completely, or is enfeebled for life, or dies. In the first of these three contingencies everyone is satisfied; in the second and third there has been a mishap for which the surgeon admits no responsibility, and there is no competent authority which can call him to account. The patient's friends cannot question what has happened; it is assumed that the surgeon did his best; both he and the patient have been unfortunate—that is all—and there the matter ends. But these are not the worst of A Layman's Fears. What if physician and surgeon are dishonest? The doctor may advise an operation which he knows to be unnecessary and may recommend the name of a particular surgeon to perform it, not because he is the best man, but because there is a secret arrangement between the pair to split their fees. How, asks Mr. Chettur, are these malpractices to be stopped? How are surgeons to be brought under control so that they shall be required to give an account of their work to the satisfaction of a body competent to judge? Undeterred by a problem almost as difficult as if the Bar Council and the Law Society were authorised and expected to exact a personal explanation from every lawyer whose client failed to secure judgment for the full amount claimed, Mr. Chettur proposes his remedies. India should have her own college of surgeons and her own standardised hospitals and should thereby set up an efficient control of the operating surgeon; operations must be performed nowhere else but in the hospitals, and everyone who becomes a Fellow of the Indian College must first solemnly and expressly repudiate and abjure the splitting of fees in any form whatsoever.

We may hope that the author of A Layman's Fears is unnecessarily apprehensive. He cites no first-hand evidence of the evils he describes. His illustrations are derived from a popular article in a non-technical periodical published in America two years ago. His attack in the *Madras Medical College Magazine* is followed by a reassuring editorial note. Members of the medical profession, observes the editor, appreciate criticism and are anxious to profit by it; they are but human beings liable to commit errors; they do not pretend to possess any supernatural powers of healing, but are taught to practise a humane art on rational lines with ordinary human judgment as their only guide. The editorial note adds, as one would expect, that the medical profession in India condemns fee-splitting as vigorously as in America. The suggestion of the total hospitalisation of medical practice is a dream impossible of realisation in India for many generations to come. In so far as surgeons are indicted, it is answered that there are as yet very few practitioners of surgery in India, not enough to form an Indian College of Surgeons. The time for such an institution will come some day. Meanwhile India must be content with the number of her medical associations, each of which already repudiates the malpractices attacked in Mr. Chettur's frank, if over-anxious, article.

ROYAL LEAMINGTON.

MOST of Leamington was built at a time when tasteful symmetry and open spaces were in fashion. It is a pleasant town, for its wide streets, innumerable trees and painted houses recall the Regency, and it is situated along a typically English river set about with gardens. Celebrated as a centre for hunting, Leamington lies in some of the best country in the Midlands, and the visitor can make excursions to many interesting places near and far afield. These amenities and an admirable train service from London are enough to make the town attractive both to those who want quiet recreation and to their friends. It was not, however, for this reason that the place originally became celebrated, but rather on account of its medicinal springs. In mediæval times the Leamington waters were believed to have healing qualities, and it was around them that the present town grew up towards the end of the eighteenth century. Quickly it became a fashionable spa, and soon after her accession Queen Victoria bestowed on it the title Royal in recognition of treatment she had taken there. Since then the fate of many other English spas has overtaken Leamington. A disbelief in empirical remedies, not least evident amongst spa practitioners, has reduced the number of patients, and the seasonal exodus of rank and fashion has been diverted abroad. It is to be hoped that its fortunes may revive with the increased facilities for treatment inaugurated by Sir Kingsley Wood last Saturday. The special characteristics and indications of English spas have too often been forgotten in their anxiety to reproduce the equipment of foreign competitors, and since this imitation has not always been founded on belief it has not always been successful. But the therapeutic uses of such agents as climate, heat and cold, and a régime daily enforced and regulated by a physician, are undeniable, and there is no reason why the present revival of British spas should not continue. There is, indeed, every reason why the greatest possible use should be made of these centres of recuperation, where the public ought to be re-educated in the principles of health just as tuberculous patients are re-educated at sanatoriums. And where the medicinal waters of any place are suitable for particular ailments the fullest possible use should be made of them. If the spas are to be effective they should not be all of a kind, all offering the same treatment and the same facilities. Their local and therapeutic personality should be preserved. The success of continental spas, moreover, largely depends on the atmosphere of confidence engendered by the doctors who give the treatment, and the doctor who does not believe in what he is recommending cannot possibly inspire this faith.

As a secondary consideration equipment and apparatus are useful, and in so far as the excellent facilities now provided will assist Leamington to become a really valuable spa the town is to be congratulated on its enterprise.

Dr. C. Rasch, professor of dermatology in the University of Copenhagen, will give an address entitled Some Historical and Clinical Remarks on the Effect of Light on the Skin and Skin Diseases at the Royal Society of Medicine on Thursday next at 5 P.M.

THE Harveian oration will be delivered at 4 P.M. on Monday next by Sir John Rose Bradford. Dr. F. G. Crookshank will give the Bradshaw lecture on the Theory of Diagnosis on Nov. 4th, and the FitzPatrick lectures will be delivered by Dr. Arthur Shadwell on Nov. 9th and 11th, the subject being Medicine in Ancient Assyria. The David Lloyd Roberts lecture will be on Racial Degeneration, and will be delivered by Dean Inge on Nov. 19th. All these lectures will take place at 5 P.M. at the Royal College of Physicians of London, Pall Mall East.

Sir James Barr, who retires from professional work and leaves Liverpool at the end of this month, has been associated with that city since 1874, when he came to the Northern Hospital. Three years later he was appointed medical officer at the Old Kirkdale prison, where defective food, ventilation, and lighting gave rise to a high disease and death roll. In characteristic manner he set about putting these matters right, with results which are well known and remembered, for his findings became the basis of the new prison regulations when the prisons were taken over by the Home Office.

Obituary.

GEORGE JAMESON JOHNSTON, M.B., F.R.C.S.I.,

PROFESSOR OF SURGERY, ROYAL COLLEGE OF SURGEONS IN IRELAND.

Prof. Jameson Johnston died very unexpectedly on Oct. 8th at his residence, FitzWilliam-place, Dublin. He had suffered from slight chest trouble for a week or ten days, and was apparently convalescent, when serious symptoms set in, and the end occurred in a few hours. He was about 60 years of age.

George Jameson Johnston was a native of Co. Tyrone, and received his early education at the Royal School, Dungannon. He entered the medical school at Trinity College, Dublin, where he received his medical education, but he took his medical degrees from the Royal University of Ireland. Having been awarded honours in biology more than once, he passed M.A. of that University in 1891, and proceeded to the M.B. degree in 1894. He became a Fellow of the Royal College of Surgeons in Ireland in 1898. He was for many years a demonstrator of anatomy in the School of Physic, Trinity College, and he conducted private classes with great success. Having spent a year as assistant surgeon to the Richmond Hospital, in 1896 he was elected visiting surgeon to the City of Dublin Hospital, to which institution he was senior surgeon at the time of his death. He had been professor of surgery in the schools of surgery of the Royal College of Surgeons for several years past. Although he frequently contributed to the medical journals, it was mainly as a surgical teacher that Johnston had a very high reputation. He was clear, practical, incisive, gifted with humour and power of repartee, and his classes both in the school and in the hospital were always crowded. Personally he was held in great affection both by his pupils and by his professional brethren. His brusque and direct manner —characteristic of the northern type—failed to hide the real kindliness, friendship, and honesty that lay beneath. Sorrow for his unexpected death will carry with it deep sympathy with his young wife, to whom he had been married for little more than a year.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXCIII.

THE TREATMENT OF SENILE INSANITY.

I.—PRESENILE MENTAL DISORDERS.*

IN this article the term presenile is applied to mental disorders arising in the period of life beginning in the late 'forties and extending to the early 'sixties. This period includes the climacterium in women, and certain common mental disorders met with in both sexes during the years which precede the actual period of old age or senility.

The more frequent clinical types of mental disorders that are encountered during the presenium are as follows: (*a*) anxiety attacks; (*b*) involutional melancholia or, more rarely, excitement; (*c*) arteriopathic insanity; (*d*) Alzheimer's dementia.

Anxiety States.

Most of these patients have struggled with psychological difficulties throughout life, with more or less successful adaptations which arrival at the presenile period of life will often upset. A frequent result is an attack of anxiety, popularly referred to as "nerves."[2] Some patients begin to fear that their work is inaccurate, become irritable, and unable to make decisions. Others will go from doctor to doctor, dogged by the fear of cancer, or some other disease from which a parent may have died. Such examples seldom become certifiably insane, and treatment will do much for them, though great patience is necessary. A complete physical examination is desirable in order to reassure the anxious patient. Teeth may require attention, and visual errors should be corrected with suitable glasses; the importance of sleep and of proper bowel actions should not be forgotten. A watch should be kept on the weight, and any indiscretions in diet or hours readjusted. A weekly interview of 20 minutes or half an hour will work wonders in allaying the anxiety, if the practitioner can listen with sympathy to the extravagant and fantastic terrors which such patients long to tell to someone who will not laugh at them. Psychoanalysis should not be advised at this comparatively late age. Stern insistence by the physician on some daily ritual, such as deep breathing, a cold sponge, or an hour's walk will be found of material help. Endocrine therapy is a useful adjunct in many cases, and a pluriglandular tablet, two or three times a day, may be prescribed. Lastly, some attempt should be made to find the patient a new interest in life. Golf, a week-end cottage, fishing, gardening, an allotment, photography, wireless, the keeping of pet animals or chickens—some new outlet can be found to suit every taste and purse. In the search for hobbies any form of motoring should be avoided.

Involutional Melancholia.

Depression is by far the most common mental disturbance of the presenium. The onset occurs usually during the 'fifties in men, and earlier in women. In most cases the depression appears for the first time, there being no previous history. Sleep is seriously delayed, and insomnia may become absolute. The irritability and seclusiveness of the patient are the despair of his family. Alarming delusional ideas become prominent. The successful man begins to insist that he has no money. Others blame themselves for all sorts of offences against nature and society, or assert that their bodily organs are dead or diseased. Some cases develop ideas of persecution and espionage, or declare that poison is being inserted into their

* An article by Dr. James on the Treatment of Senile Mental Conditions will appear next week.

food. Despair, remorse, self-pity, self-reproach, are common emotional reactions in the depressive condition, states which are accompanied by the manifestations of fear or anxiety, and lack the characteristic inertia of manic-depressive melancholia. The diagnosis must rest on an accurate history and a careful physical examination. A late paresis must always be excluded. Paralysis agitans not infrequently begets a querulous hypochondriasis.

Poor persons can hardly ever be successfully nursed through such an illness at home. When such patients are obviously insane from the legal point of view, they are best sent to the observation ward of the local Poor-law institution, whence they will be transferred to a public mental hospital. Patients with ideas of financial ruin and past sin are almost always potential suicides, and it cannot be too strongly impressed on practitioners that they should warn the family without delay of the risk that exists. Where there is a fear of active suicidal impulse, or pronounced abstinence from food, the practitioner should not hesitate to advise admission into a mental hospital. Where means and good surroundings are available, and the depression is not deep enough to influence conduct unduly, treatment at home, or in a nursing home, may prove successful, though for many reasons these patients undoubtedly do better away from home. Two nurses will be necessary, and male nurses have definite advantages for male patients in this type of illness. The essential part of treatment at first is rest, preferably in bed. All work must be forbidden. A warm bath should be given night and morning; the diet should be liberal though light, and meat allowed only once a day. It will be found that persuasion will have to be exercised to induce the patient to take food regularly. It may safely be assumed that the patient is constipated. Moreover, there seems to be an obstinate stasis of the large intestine, and a tendency for fæcal material to accumulate. A high, copious enema should therefore be given daily for a few days. The bowels will then have to be kept active; one or more vegetable laxative pills at night, which should contain strychnine and aloin, followed by a saline draught or an effervescing preparation in the morning, will suffice. Paraffin and similar lubricants are rarely successful. Sleep must be secured with a sedative. Light cases may respond to a bromide mixture; 5 gr. each of the three common bromide salts, a little Fowler's solution, and ℥xxx. of tr. hyoscyami makes a useful evening draught. As a rule, more definite hypnotic treatment is necessary, and medinal, gr. x., amylene hydrate ½ to 1 drachm in water, or the offensive but safe and excellent paraldehyde from 1 to 3 or 4 drachms, may all be tried until suitable results are obtained. Chloral hydrate and sulphonal should be avoided. Many patients of this class are cold at night, and hot bottles and ample warm bed clothing must be available, even during the summer months. The weight should be charted weekly, and every effort made to secure a steady gain. Some cases will be agitated, restless, and difficult to control. Half- to one-drachm doses of liquor morphinæ bimeconatis, three times a day, will help to diminish the restlessness; ℥ x. to ℥ xxx. of tr. opii may also be tried, but the constipating effect of this preparation should be remembered. After three or four weeks' rest, massage in bed may be given daily. If improvement is maintained, the patient may be allowed up for an hour or two in the evening. Gentle walking exercise comes next. A return of unfavourable symptoms, such as loss of weight or insomnia, should be dealt with by a return to bed. After a suitable convalescence and change to seaside or country, the patient, if keeping up his weight, should be encouraged to return to work. It is important to make a complete physical overhaul, including chemical and bacteriological examinations of the urine, X rays of teeth and sinuses, blood chemistry, fæcal investigations, &c., with a view to discovering some possible source of chronic infection. If found, it should be corrected. Dental extractions should be done gradually. If operative measures are necessary care must be taken to ensure that the patient does not receive too much warning, since he anticipates such performances with intense suffering.

Involutional Excitement.

Isolated cases of excitement occurring for the first time in the presenium are uncommon, but do occur. Extravagance in dress and living menace the family fortunes, and unfortunate love affairs with young women or young men are frequent events. If the patient is certifiable, legal care should always be recommended. If not certifiable, the patient will maintain that he or she has never been better in his or her life, and that doctors are a pack of old women. Under these circumstances a discussion of treatment by the practitioner is rendered superfluous.

Arteriopathic Insanity.

This results from sclerosis of the cerebral arteries, with or without high systolic and diastolic blood pressures. A cerebral hæmorrhage may be the first evidence of the condition. On the other hand, fleeting symptoms, such as a temporary loss of power, aphasia, or momentary confusion may last for years. Arteriosclerotic patients become very unstable emotionally, weep or laugh immoderately on the slightest pretext, and sometimes become intensely suspicious. In cases associated with high pressures, episodes of confusion and vertigo may be accompanied by attacks of vomiting. The diagnosis must rest on the physical signs, and here assistance may be gained from an ophthalmoscopic examination of the condition of the retinal arteries, which provide a guide to the state of the cerebral arteries.

Constant wandering from home, and violence towards other members of the family, are conditions which require immediate certification. Delirium following a "stroke" and dirty habits will also generally mean admission to an institution; but energetic treatment at home produces excellent results. The sufferer must be put to bed and kept there, and given morphia if necessary. The best purge is 5 or 6 gr. of calomel, followed by copious saline draughts. For several days the patient should be starved as far as is practicable. A little milk pudding, or dry biscuits, milk and eggs, is all that should be allowed for a fortnight or more. Alcohol and tobacco are forbidden. As improvement takes place, and when the blood pressure falls, the patient may be got up. His future life must be carefully regulated. Work is reduced to a minimum, and rest in bed at the week-ends insisted upon. A mercurial purge should be given once a week, and nitrites may be useful if pressures become high. Iodides seem to assist some patients. The heaviest meal must be taken at midday, and is the only one which should contain meat. A great deal can be done for the arteriopathic patient if he is treated early, and before a gross focal lesion has taken place.

Alzheimer's Dementia.

This condition is rare, and is mentioned because cases do occur in the presenium, their progress being rapid, and termination fatal. It occurs as early as the third decade of life, and is characterised by a sudden progressive mental deterioration, with profound amnesia, hallucinations, a stammering repetitive speech, and convulsions. Nothing can be done save to arrange adequate nursing care, and these patients almost invariably find their way into a mental hospital.

G. W. B. JAMES, *M.C.*, M.D., D.P.M. Lond.,
Resident Physician, Moorcroft House.

A NEW SURGICAL APPOINTMENT.—The Board of Management of the Manchester Royal Infirmary has decided to create a new honorary post in the surgical staff by the appointment of an honorary surgeon to specialise in diseases of the brain and spinal cord requiring surgical treatment. The new honorary surgeon will give his attention entirely to this kind of work.

Special Articles.

VITAL STATISTICS OF 1924–25.

THE REGISTRAR-GENERAL'S STATISTICAL REVIEW.[1]

THE tabular statement of deaths in England and Wales during 1925 is now published, a fact which we believe implies considerable speeding up as compared with experience in recent years. Late in July the portion of the Annual Statistical Review for 1924, described as "Text," was published; and the extremely valuable summary of comparative experience in regard to deaths and causes of death for which all persons interested in our vital statistics look eagerly is also at last made available for 1924. Although the tables for 1925 will doubtless be useful to many statistical workers, especially to public health officials, we must wait presumably another six or nine months for the Registrar-General's own comments on the year 1925. Meanwhile it may be noted that the national death-rate continues low; that, as compared with all pre-war years, the death-rate at each successive age-period right up to 85 is lower than in the past; the rate of infant mortality per 1000 births was only 66 for female and 84 for male infants. Enteric fever only caused 766 deaths in England and Wales. This gives a death-rate of 19 per 1,000,000 of population, as compared with 35 so recently as 1915. The death-rate from tuberculosis was 54 times as great as that from enteric fever, illustrating the greater difficulty in controlling respiratory than alimentary infections. And yet the death-rate from tuberculosis was lower than that in 1885, in the ratio of 100 to 42.

Child Mortality and Birth-rate.

Turning to the "Text" for the year 1924, it is important to note that infant mortality at ages under 4 weeks has declined since 1911 from 40 per 1000 births to 33 in 1924, a decrease of 17·5 per cent. This decrease, although small as compared with the decrease of 53·3 per cent. at ages 1–12 months, is nevertheless significant; and it is important in view of the frequent statement, erroneously made, that this early infant mortality has not declined and probably is irreducible. The whole of the section of the "Text" dealing with infant mortality is well worthy of study by medical officers of health and medical officers of child-welfare centres. Attention should be drawn to the paragraph on p. 23 dealing with death-rates at ages 1–5. At this period of life susceptibility of mortality to environment may be regarded as at its maximum, and if, as the "Text" thinks likely, the lower birth-rate has helped in making some improvement in this direction, progress cannot be expected to continue for long at the present rate, "for the birth-rate, though it may continue to fall, cannot long do so at the present rate consistently with national survival."

Acute Infectious Diseases.

The striking decline in deaths from typhoid fever continues; it is significant that the death-rate from this disease, while nearly equal in town and country, is at its maximum in the smaller towns. The death-rate from measles, though subject to epidemic variations, is declining. Of the many points suggesting further inquiry we note the greater mortality from measles of males at ages under 2, and of females at higher ages. London has far and away the highest death-rate from measles, its figures, 285 per 1,000,000, contrasting with 120 for all areas. Why should this be? Diphtheria, although now as preventable as small-pox or typhoid fever, was the registered cause of 2501 deaths in 1924 and 2774 in 1925. These numbers deserve to be particularly watched, for their magnitude will be a measure in the next few years of official medical, non-official medical, and parental care and intelligence, which could hardly be surpassed in delicacy and exactitude. The abolition of diphtheria does not necessarily involve the artificial immunisation of the majority of the child population, however desirable this is; it may be approximated by prompt medical attendance and equally prompt administration of diphtheria antitoxin, without waiting for the results of throat swabs. Encephalitis lethargica was the ascribed cause of 1407 deaths in 1924 and 1372 in 1925, the highest death-rate in the 1924 returns occurring at ages 0–5 and 55–65. The mortality from this mysterious disease was heaviest in the north of England, and there, as elsewhere, it was highest in urban districts.

Tuberculosis and Syphilis.

The sections of the "Text" dealing with tuberculosis and with syphilis especially deserve study. For six years in succession the mortality from tuberculosis has been lower than in any preceding year. It has declined by 8 per cent. in four years. There are some valuable remarks as to the effect of war conditions in altering the maximum age incidence of the tuberculosis death-rate. For males the highest rate in 1924 was at ages 45–55 and for females at ages 20–25. At the last-named age the death-rate of females was practically identical with that of males. Whether this is a direct effect of war events, or represents a change in the industrial conditions of women, can scarcely be decided until a few more years' records are available. On p. 51 is an interesting diagram giving the annual death-rate from syphilis in each year 1901–24, based on the aggregate deaths returned as due to syphilis, to general paralysis of the insane, and to aneurysm. For the seven nearest years in succession each annual death-rate is lower than its predecessor, and the extent of the decline is remarkable. This decline and its possible social and medical causes are deserving of special note.

Cancer.

The studies in this review on cancer are most important, following as they do on a series of similar studies in preceding reports. The registered cancer mortality still increases, that from carcinoma much more rapidly than that from sarcoma. The death-rate is in part a function of age, being higher at ages 45–55 than at ages 35–45 by 216 per cent., at ages 55–65 by 145 per cent., at ages 65–75 by 83 per cent., and at ages 75 and upwards by 32 per cent. than the death-rate of the immediate preceding age-period. Except at the age-period 45–55 the cancer death-rate is higher in males at all the significant ages. The present tendency is for the excess of male over female mortality to increase. Comparing standardised rates for the two sexes, that for males, when compared with the four years preceding the war, in 1924 had increased from 90 to 100, while that for females had moved only from 97 to 98. This more rapid increase for males is largely due to the decreasing share of the sex organs in the female death-rate; and the fact that the death-rate from uterine cancer and the death-rate from mammary cancer are moving in opposite directions suggests several lines of pathological and social investigation.

Other Causes of Death.

Rickets and diabetes form the subject of interesting paragraphs, as does also alcoholism. There is a careful analysis of deaths from heart disease, which shows how important it is not to think of this registered cause of deaths as a single entity of simple causation. The sections on bronchitis and pneumonia are important. There is evidence of a general tendency to substitute broncho-pneumonia for bronchitis at ages under 5; but inasmuch as the combined death-rate under the two headings has not increased, there is a satisfactory reduction of respiratory infection in early life. Gastric ulcer has now become preponderantly a fatal disease in males, and its statistics furnish interesting problems for clinicians as well as

[1] (*a*) The Registrar-General's Statistical Review, 1925. Part I.: Medical. H.M. Stationery Office. 15*s*. (*b*) Ditto for the year 1924. Text. 5*s*.

for statisticians. A similar remark applies to the now stationary death-rate from appendicitis. The puerperal mortality-rate has remained stationary during the last 14 years, suggesting reflections of a not very happy character. The section on deaths from anæsthetics should be pondered by everyone who has to administer them, and that dealing at length with accidents due to motor vehicles demands the attention of the whole community.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Royal Infirmary: The New Radiological Department.

ON Saturday last the Duke of York opened the new radiological department of the Royal Infirmary, Edinburgh. Besides being a splendid addition to the technical equipment of a great hospital, the department is a symbol of the new policy animating Scottish medicine. Many years ago an English member of the Royal Commission on Poor-laws was conducted over the Royal Infirmary by the medical superintendent of that day. As he came away, much impressed with what he had seen, he turned to an officer of the public health service and remarked: "But surely you would not municipalise this?" He had the curious idea that the only thing that could be done to extend the resources of a great national institution was to municipalise it. It had to be explained to him that the Royal Infirmary of Edinburgh drew its life-blood from all Scotland; that it was an essential part of two medical schools; that it was a great training school for physicians and surgeons, a much desired training school for nurses; and that it performed the full functions of a general national hospital for Scotland, for a great part of the south-eastern province and for the city of Edinburgh itself, drawing its students from all over the Empire and from abroad. One does not municipalise institutions that have grown up on this national scale; that is far too small an idea to apply. The Royal Infirmary, of course, has points of contact with the public services; but it is itself a living institution whose life seems to grow more intense with the years.

The new department is equipped on a scale hitherto unknown to Scottish institutions. The building is about 160 feet in length, with an average width of 60 feet, and has a basement, two floors, and a flat roof; it is designed to carry another floor if found necessary at a later date. The basement contains the generating electrical plant, mechanics' workshop, and general storage rooms. On the ground floor are the screening and treatment rooms, a lecture hall, and the various private rooms and offices. The first floor has accommodation for electrical and massage treatment, remedial exercise, a radium department, and rooms for treatment by artificial sunlight. The usual method of affording protection to members of the staff against constant exposure to the X rays is to cover the walls and doors with heavy sheet lead. The cost of this would have been prohibitive, and it was decided that the protection must be incorporated in the building material used to erect the walls. Experimental partition slabs were made and tested, the slab selected being composed of one part rough sand, two parts engine ashes, one part Portland cement, and three parts barium. As a further protection, the walls, ceilings, and floors are plastered on each side with a ⅝-inch coat of barium plaster.

The department has been erected at a cost of about £52,000. The director is Dr. Woodburn Morison, and his assistants Dr. John O'Sullivan and Dr. W. Crichton Fothergill, and it is satisfactory that the disabilities under which they have been working are now removed and that Edinburgh has the benefit of one of the best equipped radiological departments in the world.

Poor Relief and the Coal Strike.

Within the last few months there has been evidence of discontent among the parish councils, arising from the duty required of them to give relief to the wives and children of miners on strike. As this is the time for preparing the annual budgets of the parishes the occasion is taken to dispute the legality of the relief given, and a little time ago the Parish Councils' Association arranged a discussion on the whole problem. By Scottish law it is not legal to give relief either to able-bodied or the dependants of able-bodied except in terms of the Act of 1921, where the applicant is unable to find work. This, of course, does not apply to a striker; yet the parishes are asked to relieve, and do relieve, the dependants of strikers. Scottish Poor-law authorities are nothing if not argumentative, and, as the new burdens on the rates are serious, it was inevitable that someone should raise the legal question in the courts. A case is now pending and a decision is expected when the courts assemble this month. It has, however, been publicly announced that, in the event of the decision being unfavourable to the tenor of the circulars issued by the Scottish Board of Health, the Government will take the necessary measures to regularise the position.

Dr. Claude Ker.

A tablet has recently been unveiled in memory of Dr. Claude Ker, late medical superintendent of the Edinburgh City Hospital at Colinton. To every British student of fevers, Dr. Ker's masterly work was well known, and when, under stress of duty, he died before his time, this field of medicine lost an authority. Claude Ker had many friends and no enemies. He had a rare charm of personality. It is a gratification to everyone that knew him, lay and medical, to see this tribute to his memory. It was an inspiration to watch the informed enthusiasm with which he studied each new departure, recording with his own pen, so as to eliminate the personal equation, two or three lines of treatment of this disease or that, in order that he might learn directly the values of one treatment against another. There was nothing in the modern study of fevers that he could not handle with the light touch of a master.

Rickets in Scotland.

At the opening of the Springburn Child Welfare Centre in Glasgow last week, Major Walter Elliot, Under-Secretary of State for Scotland, announced that it had been arranged that a committee consisting of expert nutritionists, clinicians, and administrators should make further concerted inquiry into the problems of rickets in Scotland.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Small-pox Epidemic.

PARIS is now in the throes of a fresh epidemic of small-pox. The first cases appeared almost simultaneously towards the end of the second week in September in six arrondissements and three communes on the outskirts of the city. The multiplicity of infective foci caused some anxiety; for although it is relatively easy for the public health authorities to check the spread of small-pox breaking out at a single point, it is another matter to be sure of dealing with all sources of infection when these are numerous. The multiple origin is a sign that the small-pox germs escaped the measures taken for disinfection, or that some of those who caught the infection had it so slightly that they were never recognised and isolated. This makes it clear how important is the coöperation of all practitioners who may have a chance of detecting carriers and securing their segregation. Dr. Camus, director of the vaccination service of the Académie de Médecine, has pointed out that for three months there has been a small centre of infection not far from Paris. This centre, which has perhaps had something to do with the Parisian epidemic itself, has been the starting-point of a long chain of infections which could easily have been broken if medical men had been warned of the presence of small-pox in their area.

Hexamine in Typhoid Fever.

The use of hexamine (urotropine) in typhoid fever has long been recommended. Dr. Chalier and Dr. Grandmaison, of Lyons, have been giving it intravenously as a routine method of combating the development of typhoid bacilli in the blood, and report that when it is given early this treatment prevents complications and relapses. The drug is eliminated in bile and urine and is especially useful in protecting the patient against biliary complications such as hepatitis, acute or subacute angiocholitis, cholecystitis, and post-typhoidal gall-stones. It is also used, of course, for disinfecting carriers. In the 160 cases on which Dr. Chalier and Dr. Grandmaison report, the general symptoms were distinctly improved and diarrhœa, in particular, seemed less common than usual. There were no intestinal hæmorrhages whatever.

Arsenical Drugs in Amœbiasis.

It is generally considered in France that arsenobenzenes given by the mouth form the best treatment of amœbiasis and that they are equally useful in other intestinal parasitic infections of the same kind Dr. Ravaut uses compressed tablets of novarsenobenzol in doses of 10 cg., recommending that they should be broken up into small portions before swallowing, so that the active principle may be liberated in the digestive tract. Arsenobenzol by the mouth has not the same disadvantages as when it is given by injection. It is well tolerated and can be used without danger in doses of 0·2–1·0 g. during 24 hours. Its effect is remarkable and the cysts of the amœbæ sometimes disappear in a couple of days. In acute and subacute cases treatment by injection is indicated, but in the chronic forms oral or rectal administration is preferable as it is the only one which secures removal of the cysts.

Accidents of Spinal Anæsthesia.

After spinal anæsthesia shock may show itself in various ways, particularly in vasculo-nervous troubles and in functional disorders of the viscera and organic structures connected with the vegetative nervous system. Dr. Daniel, of Bucharest, has lately reported to the Académie de Médecine that in order to avoid such sequelæ he has been using intravenous injections of cerebro-spinal fluid. Assuming that accidents following spinal anæsthesia are anaphylactic in origin and are determined by disturbances of the vago-sympathetic he considers that the preliminary injection of cerebro-spinal fluid introduced in small quantity into the blood stream produces a slight shock which causes temporary desensitisation and has the effect of protecting the body against the sudden shock caused by penetration of the anæsthetic.

Treatment of Tuberculous Epididymitis.

Dr. Jean Tissot and Dr. Chaignon recommend the use of benzyl-cinnamic ether for tuberculous epididymo-orchitis. The drug is well tolerated. Pain disappears after three or four injections, and tuberculous nodules are absorbed without breaking down, whilst necrotic tissue disappears with rapid cicatrisation. One of their patients, thanks to this treatment, was spared orchidectomy, his weight has increased by 7 kilos, and for the past year he has had no recurrence. The drug is in an oily suspension and it is injected into the muscles of the buttock like bismuth or sulpharsenol.

First-aid Service in France.

Sponsored by Dr. Armand Vincent, a proposal is being considered to organise a first-aid and emergency medical service which will make use of aeroplanes, automobiles, and wireless telegraphy. This service would be adapted for rural requirements and would be elastic enough to meet any special local needs. Its advocates recommend a semi-official organisation.

Dr. Henri Claude, professor of psychiatry at the University of Paris, is leaving for Beyrout, on a mission connected with the systems of medical examinations there employed.

A course of curietherapy and deep radiotherapy is to be given by Proust and his colleagues at the Tenon Hospital from Nov. 15th to Dec. 16th. There will be 28 lectures and also practical laboratory work on the technique of curietherapy and deep radiotherapy, the measurement of rays and emanations, and histology. Those wishing to attend the practical course should write to the Laboratoire de Curiethérapie, Salle Duflocq, Hôpital Tenon, Paris.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Epidemic of Typhoid in Hanover.

THE epidemic of gastro-intestinal catarrh mentioned in my last letter has, unfortunately, revealed itself as an epidemic of typhoid fever more widespread than any which has occurred in this country for many years. Up to the present time more than 2000 cases have been notified and there have already been 186 deaths, although many of the patients have not yet reached the third week of the disease, when the mortality is usually maximal. Recently there has been a definite decrease of new cases, and the epidemic seems to be past its height, but the source of the infection has not yet been definitely ascertained. It was believed that the Rickling waterworks were responsible for the infection, but the chief of the Government Medical Department states that typhoid bacilli cannot be found in the water there. The Government has sent Prof. Jürgens, of Berlin, to Hanover, and he is of the opinion that the epidemic is due to other causes although his investigations are not yet complete. The public in Berlin was somewhat alarmed by the rumour that in Berlin also an epidemic of typhoid had broken out, but the authorities informed the press that the number of typhoid patients during the past six months was not more than 61—that is to say, not above the average. The authorities of Hanover have been much blamed because they were too optimistic in the beginning of the epidemic and because at a time when the alleged gastro-intestinal catarrh was recognised as typhoid they declared that the epidemic was at its end and that boiling the water was no longer necessary. Much comment is also made on the fact that no medical man is a member of the city council.

The Düsseldorf Exhibition.

The Exhibition of Hygiene (commonly called *Gesolei*) at Düsseldorf this autumn and winter is one of the largest of its kind ever held. There was a similar but international one at Dresden in 1911, but it was limited to hygiene, whilst the present exhibition, which is purely German and Austrian, includes social aid and physical culture in addition. The present exhibition is of enormous dimensions. The grounds are in a beautiful situation on the banks of the Rhine which is here rather shallow but nevertheless imposing in its width. Prof. Schlossmann, of Düsseldorf, the well-known specialist in children's diseases, is the principal originator of the exhibition, the main object of which is to make hygiene interesting to the lay visitor by means of pictures, diagrams, and exhibits. The healthy body is shown by transparencies in such a way that the visitor, by special apparatus, may see the circulation of the blood and study the function of the intestines and bladder. These objects have excited the greatest interest among the numerous visitors, as also have the models of prehistoric man shown together with excavated skulls and bones and reconstructed pile dwellings and other prehistoric habitations. Amongst many other things the exhibition illustrates the treatment of diseases and care of the sick; the work of the medical man in town and country; his training and social position, the organisation of hospitals and clinics, especially those of the Düsseldorf Academy of Medicine, which is to be enlarged into a university; the work of bacteriological and pathological laboratories and first-aid

and the transport of casualties. The German spas and health resorts have a pavilion of their own where the indications of the individual spas, the development of their institutions, the number of visitors, and pictures of their surroundings are displayed. Unqualified practice and quackery are the subject of a special exhibit showing advertisements of quacks, the expensiveness of their prescriptions, and other nuisances caused by them. Other departments are concerned with climate, food, housing, clothes, ventilation, lighting, infectious diseases and the mode of their spread, industrial hygiene, and the health of women. In the department dealing with food not only the physiology and chemistry of nutrition, and of table luxuries, tobacco, and spirits, but also the production of animal and vegetable food is shown. There is a model farm within the precincts of the exhibition where milk is shown on its course from the udder of the cow to the mouth of the consumer. Pisciculture and bee-keeping are added to the farm. In the veterinary department there are exhibits showing the conveyance of diseases from animals to men.

That part of the exhibition which is devoted to the public health work of cities is, perhaps, more valuable to the medical officer of health than to the ordinary practitioner. There is an interesting display of clothing which shows its development from ancient times until the present day, and concludes with examples of healthy and unhealthy clothes. In the department of industrial hygiene the visitor learns about insurance against illness, accidents, and factory diseases; in a great hall devoted to the hygiene of traffic specimens of hygienic railway-cars, sleeping-cars, and the like are to be seen. By no means least interesting is an exhibit showing the effect of the blockade on the general health during the war, together with a display of food substitutes then used. In the department of public health are exhibits illustrating the care of children from infancy to the time of leaving school, the combat against tuberculosis and alcoholism, the care of cripples and deaf-mutes, and the treatment of psychopathic people. Lastly, the department of physical culture gives a good impression of the development and the present state of physical exercises in Germany. The different sports are shown and there is a stadium in the grounds of the exhibition where numerous athletic events have taken place.

The exhibition, which will be closed at the end of October, is proving a great success. Many congresses have been held in connexion with it. Between Sept. 15th and 25th, for instance, there have been congresses of the German Pediatric Society, the Pharmacological Society, and the Association of Licensed Druggists, not to mention the Congress of German Naturalists and Medical Men, which was attended by about 5000 members.

New Remedy for Tuberculosis.

Foreign newspapers have published a number of rumours about the successes obtained by Prof. Erich Leschke, of Berlin, in the treatment of tuberculosis with a new gold compound called triphal. Prof. Leschke, who has not yet published his results, kindly authorises me to inform readers of THE LANCET that he has been using triphal for more than a year and that he gives injections of 0·25 g. at intervals of four days. The exudative and nodular forms of tuberculosis, he finds, are equally suitable for the treatment, and he also administers the compound before performing a pneumothorax in cases of tuberculosis of both lungs, where there is a cavity in one lung and nodular lesions in the other. Prof. Leschke states that his results are satisfactory and encouraging, but he desires to point out that it is much too early yet to give information about his work to the lay press. In a few months' time he hopes to publish in the *Zeitschrift für Tuberkulose* an account of his methods and results.

Plasmochin.

You have already commented on the announcement of a new remedy against malaria made at the Düsseldorf Congress by Profs. Sioli and Mühlens. The great merits of plasmochin are that it is cheaper than quinine, tastes better, and gives rise to less unpleasant secondary effects. It is, however, not efficacious as a prophylactic, and when the dose is pressed beyond 0·1 g. cyanosis may occur and serve as a warning against further increase. It seems that children and even infants can take plasmochin without danger.

Death of Prof. Kräpelin.

Prof. Emil Kräpelin, who died at Munich at the age of 71, was one of the most eminent alienists of the present time, and was well known for his application of the methods of experimental psychology to the study of mental pathology. He threw new light on circular insanity, first described schizophreny, and wrote on the influence of drugs on mental diseases, and on hallucinations. His text-book on psychiatry has become a standard work. Prof. Kräpelin not only studied the purely medical side of mental diseases, but also their forensic aspect and especially the reform of the criminal code. He studied the psychology of criminals, advocated a mental hygiene which he believed to be just as important as bodily hygiene, and worked with great energy against the drinking habit. He became professor at Dorpat University in 1886, at Heidelberg in 1890, and at Munich in 1903. He was the founder of the Institute for the Study of Mental Diseases, of which he continued to be the head until some years ago, when according to the German law he had to retire from his chair at the university on reaching his sixty-eighth year.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENT.)

The Cancer Conference.

THE conference which has just concluded at Mohonk, a remote spot in the Shawangunk Mountains about 100 miles north of New York, was attended by the bearers of well-known names in cancer research from most European countries and the American continent. Sir John Bland-Sutton, Dr. J. A. Murray, Dr. A. Leitch, and Mr. Sampson Handley represented Great Britain, Profs. P. Marie, O. Hartmann, and Drs. Regaud and G. Roussy came over from Paris, Drs. F. Blumenthal and R. Bierich from Germany, while Italy sent Prof. R. Bastianelli, Switzerland Dr. Dubois, Belgium Prof. J. Maisin of Louvain, Denmark Dr. J. Fibiger, and Holland Prof. W. M. de Vries (Amsterdam) and Prof. H. T. Deelman (Groningen). Among the 60 or more American delegates may be mentioned the names of Greenough, Bloodgood, Woglom, Fielding Service, F. C. Wood, W. H. Welch, C. H. Mayo, J. B. Murphy, and Maud Slye. Mr. Soper acted as managing director; he it was who chose a secluded spot where deliberations might be undisturbed and on whom fell the duty of issuing an agreed statement to the press. Apart from this it is understood that the French delegates pronounced against the acceptance of a filtrable virus as the cause of cancer, and that Dr. Louis Dublin, of the Metropolitan Life Insurance Company, insisted on the need for a hundred-fold increase in expenditure on cancer research in view of the enormous increase of the disease in the States during the last 15 years.

An Agreed Statement.

Although the present state of knowledge of cancer is not sufficient to permit the formulation of such procedures for the suppression of this malady as have been successfully employed for the suppression of infectious diseases—this is how the statement opens—there is enough well-established fact and sound working opinion concerning the prevention, diagnosis, and treatment of cancer to save many lives, if this information is carried properly into effect. While the causation of cancer is not completely understood, it may be accepted for all practical purposes that cancer is not contagious or infectious. Nor is it

hereditary, although a certain predisposition or susceptibility to cancer is apparently transmissible through inheritance. This does not signify that because one's parent or parents or other members of the family have suffered from cancer, cancer will necessarily appear in other persons of the same or succeeding generation. The control of cancer, so far as this subject can be understood at the present time, depends upon the employment of measures of personal hygiene and certain preventive and curative measures, the success of which presupposes intelligent coöperation on the part of patient and physician. Persons who have cancer, no matter in what form, must apply to competent physicians at a sufficiently early stage of the disease in order to have a fair chance of cure; in some forms early treatment affords the only possibility of cure. Cancer in most parts of the body can be discovered in a very early stage, and if cases are treated properly the prospect for permanent cure (so the statement runs) is good. Since the cure of cancer depends upon the discovery of the growth before it has done irreparable injury to a vital part of the body and before it has spread to other parts, efforts should be made to improve the method of diagnosis in these various locations and the treatment of cancers so discovered. The public, therefore, must be taught the earliest danger signals of cancer which can be recognised by persons without a special knowledge of the subject, and induced to summon competent medical attention, when any of these indications are believed to be present. Over and above this there is much for medical men to do in the detection of early cases and in referring patients to institutions where diagnosis can be made and proper treatment applied. The more efficient the family doctor the more ready is he to share responsibility with the specialist. He can also help by referring cases of cancer which he discovers to local physicians skilled in its treatment. The most reliable forms of treatment, and, in fact, the only measures thus far justified by experience and observation, involve the application of surgery, radium, and X rays. Efforts towards the control of cancer should be made in two principal directions: the promotion of research in order to increase existing knowledge and the practical employment of the information already at hand. Even with our present knowledge, the statement concludes, many lives could be saved which are sacrificed to unnecessary delay.

The Boston Psychopathic Hospital.

The Boston Psychopathic Hospital publishes under one cover the reports of its many coöperating departments. The executive staff are responsible for the general running of the hospital and the coördination of its workers; they are also the medium of communication with the public and have a most important educational function. The number of cases requiring treatment is almost overwhelming, and it is a constant task to keep pace with the daily demands and yet collate and collect material sufficient and suitable to form the basis of research. The director gives a series of unselected cases to illustrate the diversity of the hospital's human problems. A definite advance has been made during the year under review in the vocational guidance of patients. Working through the Y.M.C.A. and the Y.W.C.A., the hospital has reached many who needed help without knowing where to seek it. The hospital has a school district allotted to it and has made a survey of retarded children and has also run a consultation school clinic, where teachers can discuss the problems presented by their pupils. About 1500 patients were admitted during the year. More work has been done on the possible rôle of endocrine disorders in the ætiology of mental disease, and the fasting blood-sugar has been estimated in 200 cases of emotional disturbance. Twenty-four schizophrenic cases have been thoroughly investigated clinically and pathologically, and the resident dentist has made careful study of the cases referred to him. The out-patient department reflects the gradual change in the public attitude to mental hospitals; the cases of frank psychoses are fewer and border-line conditions and psychoneuroses form a steadily increasing proportion. Over 2000 cases were seen during the year. The workers in the biochemical laboratory carry out routine examinations and have also investigated blood-sugar curves and basal metabolism. They have tried to estimate the value of endocrines in obesity and have proved the unreliability of the Kottman reaction as usually performed. The psychological department has prepared a statistical study of the sex life of college graduate men and developed and tested abbreviated scales of intelligence tests. The neuropathological laboratory carries out routine histo-pathological investigations and autopsies. The department of therapeutic research is responsible for the malarial treatment of general paralysis and has discharged a number of cases apparently cured. Tryparsamide has also been used with very satisfactory and lasting results. Relapsing fever has been tried, but has not proved so good, but there is hope that the spirochæte of rat-bite may prove a substitute for malaria. The social service department was crippled by illness amongst its staff, but has completed two surveys as well as the usual routine work. Nearly 1000 cases were dealt with during the year and 7500 visits were paid. Occupational therapy forms another special department, and patients have equipped the wards and roof garden; informal games and exercise have been organised.

LONDON MEDICAL EXHIBITION.

(*Concluded from p. 781.*)

LAST week we gave a brief summary of many of the drugs and pharmaceutical preparations shown at the London Medical Exhibition, which was held from Oct. 4th to 8th. Below will be found notes of other important exhibits in this category and also an account of surgical instruments and appliances, food products, and miscellaneous exhibits.

DRUGS AND PHARMACEUTICAL PREPARATIONS.

BRITISH ALKALOIDS, LTD. (104, Winchester House, London), showed their T.C.P. preparation (trichlorophenylmethyliodosalicylic acid). The drug has been incorporated in ointments and a dentifrice.—PEPSODENT CO. (42, Southwark Bridge-road, S.E.) prominently displayed their well-known dentifrice which is mildly acid and devoid of harmful effects on the enamel of the teeth, and KOLYNOS INCORPORATED (Chenies-street, W.C.), in addition to their dental cream which while cleaning the teeth cleanses the whole of the mouth, showed a useful denture powder for cleaning artificial teeth. This is put up in conveniently shaped flasks with sprinkler top. A purified skin soap was also included in the exhibit.—SANDOZ CHEMICAL CO., LTD. (Pharmaceutical Department, Bradford), among other preparations, exhibited Allisatin Brand tablets, a new and convenient method of administering allium sativum and Felamine Brand Tablets, for use in hepatic congestion, hepatic insufficiency, cholangitis, cholelithiasis, cholecystitis, jaundice, chronic constipation, after operations as a disinfectant and to stimulate digestion and bowel activity. Femergin (ergotamine tartrate, the pure active specific alkaloid of ergot of rye) was also displayed.—JOHN MORGAN RICHARDS AND SONS, LTD. (46–47, Holborn Viaduct, E.C.), made prominent in their exhibit Lactopeptine for digestive disturbances, and Antikamnia, an analgesic and antipyretic, in powder and tablet form.—BENGUÉ AND CO., manufacturing chemists (24, Fitzroy-street, W.), showed a large selection of various drugs and chemical products including Muthanol, a suspension of bismuth hydroxide and mesothorium bromide in sterile olive oil, which is claimed to be of special value in the nervous manifestations of tertiary syphilis.—BURGOYNE, BURBRIDGES AND CO., LTD. (East Ham, London), had for their chief feature a non-poisonous preparation called Zotal Liniment,

said to be an efficacious counter-irritant and stimulant. They also exhibited a physiologically tested concentrate of the fat-soluble vitamins, Neutramyne.—TETMAL, LTD. (45, Farringdon-street, E.C.), exhibited Tetmal, an antipyretic and analgesic which, it is stated, does not depress the heart or circulation, and Codlivex, a confection containing the lipoid of the liver in such proportion that one tablet is equivalent to one tablespoonful of cod-liver oil.—COATES AND COOPER (41, Great Tower-street, E.C.) showed a large number of American and German therapeutical preparations including an improved hydrate of magnesia in convenient tablet form, "Sil-A1," a physiologically pure synthetic kaolin, and the Battle Creek Food Co.'s diabetic foods.

SURGICAL INSTRUMENTS AND APPLIANCES.

MAYER AND PHELPS (Chiron House, 59–61, New Cavendish-street, W.) had an attractive display of surgical instruments and apparatus including the "Leeds" Anæsthetic Outfit, combining apparatus for administering N_2O, O_2, CO_2, open and closed ether and chloroform. Much interest was displayed in the M.P. Clinical Lamp, which, attached to an adjustable stand, has universal movements and, detached from the stand, can be used as a hand lamp, while the Musgrave Woodman Chair for operation work in the upright position received much commendation.—JOHN WEISS AND SON (287, Oxford-street, W.) who showed a wide selection of surgical instruments, drew particular attention to Gaudin's Reverdin Needles, to the Abadie Intestinal Clamps, and to the May pattern of ophthalmoscope. Many of the instruments of this firm were of stainless steel.—GENITO-URINARY MANUFACTURING CO., LTD. (64, Great Portland-street, W.), displayed a very attractive exhibit of the latest instruments for bladder and kidney surgery and instruments for bronchoscopy and œsophagoscopy, diathermy apparatus, catheters, bougies, &c., were shown in great variety.—HOLBORN SURGICAL INSTRUMENT CO., LTD. (26, Thavies Inn, Holborn Circus, E.C.), had a comprehensive exhibit of surgical appliances including Cumberbatch and Robinson's diathermy electrodes, Kielland's midwifery forceps, and electric diagnostic sets. Much interest was shown in the "Minop" knife with detachable blades, an ingenious contrivance by which separate blades can be fixed almost instantaneously to a handle, each blade being hand set.—DOWN BROS. (21–23, St. Thomas's-street) showed a representative collection of surgical instruments and appliances, special attention being called to their improved operation table.—H. PFAU Inhaber L. LIEBERKNECHT (Berlin, N.W. Louisenstrasse, 48) demonstrated surgical instruments for ear, nose and throat work.—SURGICAL MANUFACTURING CO., LTD. (83, 85, Mortimer-street, W.), who are the makers of the well-known "Barton" Sphygmomanometer, drew attention to their "Glasgow" operation table, its universal movements and compact construction making it suitable for large or small institutions, and displayed a wide selection of hospital and consulting-room equipment.—HERBERT E. KENDRICK (342, St. John-street, E.C.), among their interesting display of metabolism and blood chemistry apparatus, drew attention to the British Benedict Portable Metabolism Outfit, a light-weight instrument for completing metabolism tests at the bedside without analysis, and to a clinical colorimeter for estimations of uric acid, urea, creatinine, and sugar in the blood.—DEVILBISS CO., LTD. (West Drayton, Middlesex, and 27, Old Broad-street, W.), had a comprehensive display of medical sprays for the nose and throat and for general disinfectant use.—INHALING DRUG AND APPARATUS CO., LTD. (30, Grosvenor-place, S.W.), showed nebulising and inhaling apparatus by which the flow and density of vapour can be finely adjusted.—G. H. ZEAL, LTD. (75 and 77, St. John-street, E.C.), displayed clinical thermometers of many patterns, including the well-known "Repello" which does not require shaking down, and the "Acello" re-setting case which resets any clinical thermometer instantly.—BRUCE, GREEN AND CO., LTD. (14, 16, 18, Bloomsbury-street, W.C.), showed ophthalmoscopes, optical trial cases, and various types of instruments for ophthalmic work.—HAWKSLEY AND SONS (83, Wigmore-street, W.) had a variety of sphygmomanometers, clinical and recording, the Baumanometer for blood-pressure work, and a large number of recording instruments such as polygraphs and stop-watches, as well as stethoscopes, electric ophthalmoscopes, microscopes and accessory apparatus.—SHORT AND MASON, LTD. (Aneroid Works, Macdonald-road, Walthamstow), exhibited their Tycos micro-barograph which records the most minute change of atmospheric pressure, and portable and surgical types of sphygmomanometers.—A. G. SHELDON AND CO. (59, Weymouth-street, W.) showed sterilised surgical dressings and accouchement outfits in sealed tins which can be obtained at any hour of the day or night, and a variety of belts, binders, rubber sheets and similar articles for use in surgical work.

BRITISH HANOVIA QUARTZ LAMP CO., LTD. (Slough, Bucks), who manufacture quartz lamps to operate both on the direct and alternating current supply, without rectification, exhibited, among other lamps, the Artificial Alpine Sun for ultra-violet radiation, suitable for general practice, the Jesionek Quartz Lamp, suitable for large scale installations in clinics, and the Kromayer Quartz Lamp (water-cooled) for intense local application and for compression or orificial treatment in conjunction with special applicators.—ALLEN AND HANBURYS, LTD. (37, Lombard-street, 7, Vere-street, and 48, Wigmore-street), in addition to the very striking display of hospital equipment shown in the upper hall in conjunction with their pharmaceutical exhibit, demonstrated in the lower hall of the exhibition the Snook X ray apparatus, Philips Metalix tubes, and different kinds of mercury vapour ultra-violet light lamps.—GENERAL RADIOLOGICAL AND SURGICAL APPARATUS CO., LTD. (204/206, Great Portland-street), made a prominent feature of their "Heliol" Arc Lamp for direct or alternating current mains, the enclosed carbon arc emitting radiations resembling natural sunlight at high altitudes, while they also exhibited X ray outfits of various patterns including the "Explorator," an X ray apparatus for private practitioners, suitable for radioscopy, time and rapid radiography, and simple superficial therapy.—BRITISH WOLMUTH SANAWAVES CO., LTD. (25, High Holborn, W.C.), drew attention to their apparatus based upon the principle of the continuous low galvanic current for the treatment of rheumatism, arthritis, gout, neuralgia, and so forth, emphasis being laid on the fact that the enclosed batteries have a long life which makes the apparatus convenient for country work and for use in out-of-the-way places.—I. CALVETTE, LTD. (11, Little St. Andrew-street, Charing Cross, W.C.), showed apparatus for ultra-violet ray work and radiant therapy together with electrical apparatus of various kinds, diathermy apparatus for treatment by light and heat.—STANLEY COX, LTD. (30, Percy-street, W.), demonstrated their sunlight radiant heat lamps and high-frequency apparatus.—MEDICAL SUPPLY ASSOCIATION, LTD. (167/185, Gray's Inn-road, W.C.), exhibited electro-medical and X ray apparatus, hospital furniture, and surgical instruments.—KODAK, LTD. (X Ray Department, Kingsway, W.C.), had an attractive display of film negatives showing the high quality and uniformity of the "Duplitized" films, X ray prints on Kodak "Nikko" bromide paper, and dental X ray negatives on Eastman dental X ray film illustrating the new "Bite-Wing" process for the early detection of interproximal cavities. The exhibit included accessories and materials for clinical photography in great variety.

PEDESTROS, LTD. (26, Langham-street, W.), showed an interesting collection of light metal limbs.—CHAS. A. BLATCHFORD AND SONS, LTD. (90, Clapham-road, S.W.), exhibited among many forms of artificial limbs an ingenious artificial leg which requires no harness of any kind.—T. HOLLAND AND SON (46,

South Audley-street, Grosvenor-square, W.) showed appliances for the treatment of flat-foot and for the treatment of the foot generally, together with a variety of surgical boots.—W. J. WILSON AND CO., LTD. (45, Bedford-row, Holborn, W.C.), displayed light mechanical limbs of ingenious construction and also hospital furniture.

DOMEN BELTS CO., LTD. (456, Strand, W.C.), showed many belts for pregnancy, accouchement, hernia, floating kidney, and gastroptosis.—H. E. CURTIS AND SON (7, Mandeville-place, W.) made an attractive display of their abdominal supports and belts, trusses, and elastic hosiery, including an abdominal support for ptosis, and a colostomy support.

"ARDENTE-ACOUSTIQUE" (95, Wigmore-street, W.) exhibited a large number of aids for the deaf which give a good natural tone with an absence of metallic timbre, each instrument being adapted to the needs of the particular patient. Attention was specially directed to a small earpiece the size of a shilling, which, while effective, is comparatively inconspicuous. This firm had a room fitted up for practical demonstrations. —GENERAL ACOUSTICS, LTD. (Acousticon House, 77, Wigmore-street, W.), showed electrical and non-electrical aids for the deaf in great variety, particular stress being laid on the multiple "Acousticon" by means of which deaf people can hear the preacher in a church or the speaker in a public hall.—W. H. PETTIFOR (11, Victoria-street, Westminster, S.W.) exhibited electrical aids for the deaf of various patterns, attention being called to a test instrument which enables a prescription to be written for an electrical aid to give the most suitable pitch, wave form, and volume of sound for each individual patient. All these firms make a special feature of lending their appliances for home trial.

FOOD PRODUCTS.

OXO, LTD. (Thames House, Queen's-street, E.C.), included in their comprehensive exhibit a new preparation, Oxo Meat Juice. This is prepared from the natural juice of prime fresh, lean beef, concentrated by a special process which preserves the soluble proteids of the juice in their natural uncoagulated condition during the process of manufacture. In addition to the company's Oxoid gland preparations, were to be seen Oxo (cubes and bottles), Hospital Oxo, Beef Essence, Lemco, and Lab-Lemco, the last being a laboratory preparation for the cultivation of bacteria.—BOVRIL, LTD. (148–166, Old-street, E.C.). This preparation of concentrated pure beef was shown in its various forms including Invalid Bovril, Bovril and Cod-liver Oil, and Bovril and Milk.—MEAD'S INFANT DIET MATERIALS (Brookes and Warburton, Lexington-street, W.) showed milks for infants reconstructed so as to resemble human milk, dextrimaltose, a pure Newfoundland cod-liver oil, and other products which are not advertised to the general public, while feeding directions are not printed on the tins. Instructions are given to the medical attendant only.—ENERGEN FOODS CO., LTD. (Energen Works, Willesden), exhibited breads, biscuits, and other cereal products for diabetics.—S. GUTTERMAN AND CO. (35–36, Aldermanbury, E.C.) showed Cereal Meal, a combination of cereal, agar-agar, flax seed meal, and bran, for the relief of constipation.—VIROL, LTD. (Hanger-lane, Ealing, W.), demonstrated the value of Virol, a food which contains marrowfat, glycerine, malt, eggs, lime, and iron. It can be obtained also in the form of a powder mixed with dried milk. Virolax is an emulsion of liquid paraffin and virol.—VITALIA, LTD. (17A, Boniface-street, S.E.), showed a preparation under the name of Vitalia, said to contain 8 per cent. of hæmoglobin and the natural vitamins.—MALTINE MANUFACTURING COMPANY, LTD. (23, Longford-street, N.W.), displayed their Maltine, and maltine combined with cascara sagrada, maltine with hypophosphites, and maltine with creosote.—VITMAR, LTD. (Standen-road, Southfields, S.W.), exhibited Vitmar food adjuvants said to contain vitamins.

GLAXO (56, Osnaburgh-street, N.W.) showed their various milk products including Glax-Ovo, which includes malt extract and a special preparation of vitamin D, Prescription Glaxo for preparing an approximate breast milk, Standard Glaxo which is a full-cream dried milk, Glaxo Malted Food, and Ostelin, a preparation of the essential vitamin of cod-liver oil.—HORLICK'S MALTED MILK CO., LTD. (Slough, Bucks), made a feature of their easily digested and nutritious diet for invalids and convalescents which can also be obtained in the form of food tablets.—Milk and milk foods were also shown by PRIDEAUX'S PURE CASEIN AND LIFE FOOD COMPANY (16, Southwark-street, S.E.), the WEST SURREY CENTRAL DAIRY CO. (Cow and Gate House, Guildford), TRUFOOD, LTD. (Wenbury, Cheshire, and Lever House, Blackfriars, London), and Hooker's Malted Milk by THEW HOOKER and GILBEY (Buckingham).—SISTER LAURA'S INFANT AND INVALID FOOD CO. (Springfield Works, Bishopbriggs, Glasgow) displayed their wares as did also the BRUSSON FOODS, LTD. (311, Gray's Inn-road, W.C.), who showed Brusson breads for diabetes, and COATES AND COOPER (41, Great Tower-street, E.C.) who had a selection of diabetic foods.

MISCELLANEOUS.

Other exhibits were: TINTOMETER, LTD. (Colour Laboratory, Salisbury), who displayed Lovibond's Colour Scale and Tintometer apparatus for colour analysis.—GAS LIGHT AND COKE CO. (Horseferry-road, Westminster, S.W.) who demonstrated the hygienic and labour-saving advantages of gas fires and the advantages of a specially constructed lamp which, while illuminating, ventilates the room in which it is installed; the SCHOLL MANUFACTURING CO., LTD. (Granville-square, W.C.), who showed appliances for flat-foot and other disabilities of the feet; and JAEGER CO., LTD. (95, Milton-street, E.C.), who had an attractive display of pure wool underclothing and sheets, camel-hair blankets, rugs, and footwear, and garments of various kinds for men, women, and children.

LAKEROL BRONCHIAL PASTILLES (124, High-street, Shoreditch, E.) displayed their well-known bronchial pastilles whose ingredients are menthol, eucalyptus, and other essential oils with liquorice, sugar, and gum arabic; and IRVING'S YEAST-VITE, LTD. (12–16, Laystall-street, E.C.), exhibited their product for which is claimed great therapeutic value in glycosuria, septicæmia, pyæmia, and erythemas.—THERMOGENE CO. (Hayward's Heath, Sussex), PINOLEUM COMPANY, New York (Distributing Agents: Brooks and Warburton, 40–42, Lexington-street, W.), J. C. ENO, LTD. (Eno's Fruit Salt Works, Pomeroy-street, S.E.), and GRANOSE FOODS, LTD. (Watford, Herts), were amongst the exhibitors. KEEN, ROBINSON AND CO. (London and Norwich) showed Almata, a complete food for infants and invalids and nursing mothers, and "Patent" Barley and Groats; and CADBURY BROS. (Bournville) showed cocoa and chocolate in various forms.—THE FOOD EDUCATION SOCIETY (24, Tufton-street, Westminster, S.W.) and THE GARDEN CITY PURE FOOD CO., LTD. (95, Westminster Bridge-road, S.E.), were also represented by attractive stalls.

The MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY, LTD. (30, High Holborn, W.C.), which is a mutual society of medical and dental practitioners managed by members of the medical profession for the benefit of the profession, had a useful exhibit explaining various matters of life, sickness, and endowment insurance; and the LANCASHIRE AND GENERAL ASSURANCE CO. (Head Office: 8, Bucklersbury, E.C.) called attention to insurance by medical men as a special feature of their company.

SPAS AND WATERS.

BATH exhibited an attractive display of books and prints illustrating the treatment at this old British watering-place, which for 2000 years has been used for the treatment of disease. Every approved form of balneotherapy is provided by a specially trained staff.—BUXTON showed photographs of bathing

establishments and the chief features of interest in and around Buxton. The radio-active water is saturated with nitrogen and contains also helium and argon. This spa also contains a strong chalybeate spring.—DROITWICH, whose brine baths are being extended, distributed an illustrated booklet giving useful information for visitors to the spa and displayed an interesting selection of photographs. The accommodation includes the Nauheim treatment and aeration baths.—HARROGATE also had an attractive display of photographs and prints and a large number of pamphlets and booklets drawing attention to the advantages of this spa with its diversity of waters.—TORQUAY CORPORATION, South Devonshire, showed pictures and distributed literature demonstrating the suitability of this spa as an alternative to continental winter resorts for those who cannot travel abroad.—INGRAM AND ROYLE (45, Belvedere-road, S.E.) produced a fine display of natural mineral waters, salts, and pastilles, calling attention to the fact that the natural aperient mineral water, Hunyadi Janos, can now be supplied to meet any demand.

MEDICAL PUBLISHERS.

Medical books were shown by ADLARD AND SON AND WEST NEWMAN, Ltd. (23, Bartholomew-close, E.C.); BAILLIÈRE, TINDALL AND COX (7 and 8, Henrietta-street, W.C.); WILLIAM HEINEMANN (20, Bedford-street, W.C.); H. K. LEWIS AND CO., LTD. (136 and 140, Gower-street, and 24 and 28, Gower-place, W.C.); and STANLEY PHILLIPS (45, Brondesbury-road, N.W.).

A similar exhibition will be held in the Philharmonic Hall, Liverpool, from Monday, Nov. 22nd, to Friday, 26th.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdr. J. Kirker to be Surg. Comdr.

ROYAL ARMY MEDICAL CORPS.

Maj.-Gen. C. W. Mainprise, late R.A.M.C., retires on retd. pay.

Col. J. M. Sloan, late R.A.M.C., to be Maj.-Gen.

Lt.-Col. G. W. G. Hughes retires on retd. pay.

Maj. W. E. Marshall is secd. for duty with the Sudan Def. Force.

Majs. T. C. R. Archer and W. R. O'Farrell are restd. to the estabt.

Maj. A. A. Meaden to be Lt.-Col, vice Lt.-Col. G. W. G. Hughes to retd. pay.

Maj. J. A. Turnbull to be Lt.-Col., vice Lt.-Col. and Bt. Col. C. R. Evans, promoted to Col.

The undermentioned Capts. relinquish the temp. rank of Maj.: F. G. A. Smyth, W. E. Tyndall, F. C. Tibbs, H. T. Findlay, J. H. C. Walker, and W. H. Ferguson.

Capts. to be Majs.: F. G. A. Smyth, E. F. W. Mackenzie (Prov.), J. Biggam, C. Scales, D. Pottinger, J. McFadden, J. McP. Mackinnon (Prov.), D. Bell, J. S. K. Boyd, W. S. Martin (Prov.), J. J. Magner (Prov.) and remains secd., A. F. I. Patterson, G. D'R. Carr, G. P. Kidd, F. R. Fletcher, and H. W. Browne (Prov.).

Capt. B. Malaher retires, receiving a gratuity.

TERRITORIAL ARMY.

Maj. (Prov.) F. H. White is confirmed in his rank.

ROYAL AIR FORCE.

Flying Officer G. J. Hanly is granted a permanent commission in this rank.

Flying Officer R. F. G. Dickson relinquishes his short service commission on account of ill-health.

INDIAN MEDICAL SERVICE.

Capt. Sorab Dinshah Billimoria and A. S. Fry to be Majs.

ALEXANDRA DAY.—The collections on Alexandra Day in London, including a little over £4000 from other sources, produced £50,118, as compared with £45,088 last year. The expenses were £8201, £6303 of which was the cost of the roses made by cripples.

Correspondence.

"Audi alteram partem."

THE RISK OF SUICIDE IN MENTAL CASES.

To the Editor of THE LANCET.

SIR,—In commenting on a recent case of suicide at Bournemouth, the coroner appears to have considered those in charge of the patient at fault in not providing bars to the window of the bedroom. The facts of the case are simple. The patient was under certificates, on leave of absence from a licensed house, and staying at a branch house at Bournemouth. She was known to be suicidal and a nurse was continuously in attendance. She attacked the nurse and succeeded in throwing herself from a first floor room by squeezing through a narrow opening in a casement window. Death was attributed to shock rather than injury.

The coroner's criticism raises matters of importance which concern the treatment of individual patients, the care of the insane generally, and the responsibility of the nursing and medical professions.

With regard to the individual patient, it is necessary to remember that not rarely the best chance of recovery involves some measure of risk. Safety first may mean bad treatment. In this case the patient had been three years in the parent institution, and it may be presumed that the removal to the beautiful seaside home was designed to give a new outlook on life and increase the prospect of recovery. This end would have been defeated if she had been placed in a strong room with barred windows. There was, perhaps, some force in the remark of the foreman of the jury that such patients should be nursed on the ground floor, but even so, anybody who can get out of a window may get away and find a means of ending life. No one would attempt to justify carelessness or any laxity in taking precautions when patients are known to be suicidal, but broadly speaking, it is safer to trust to personal supervision than to bars or other mechanical contrivance.

That the precautions were inadequate in the present case does not necessarily mean that the arrangements at the seaside home were wrong. In dealing with such patients in spite of every care accidents happen from time to time. In the treatment of insane persons generally this same problem is ever present. Although a considerable percentage of persons under care have contemplated suicide, only a very small number are at any given time actively suicidal. Unfortunately it is impossible to be quite sure who these are, or special measures for their treatment could be made.

The question then arises, how far must the comfort and welfare of the majority be sacrificed for the safety of the few. High walls, unclimbable fences, barred windows, strong rooms, and even locked doors are rapidly disappearing from our mental hospitals, and we trust public opinion will support the change. If remarks, such as those of the coroner in this case, influence the authorities it will mean a set-back in the treatment of the insane.

I do not forget that a mental hospital must be a place of safety, and that in many cases with suicidal tendency the first element in treatment is mental rest—a rest from the constant temptations which ordinary home conditions afford. But this safety is as already said best secured by personal supervision, which must always be the first line of defence. The second line—viz., the structure and planning of the buildings and gardens—gives scope for great skill, in order that additional security can be obtained without interfering greatly with ordinary conditions of life. In certain wards the upper windows must in some way be secured and to do this without hindering with free ventilation is extremely difficult, especially in hot climates. But in spite of all contrivances the

essential difficulty will remain. If the institution is made really safe it becomes a prison; if the patient is allowed no access to tools, employment therapy is impossible; if escapes are to be wholly prevented country walks cannot be permitted, and so forth.

I believe that the true interests of the insane are best secured by a liberal policy. It may, perhaps, lead now and then to accident, but on the whole it will prevent many accidents and happier conditions of life will give better results.

Lastly, the responsibility of the nurse and the physician. Although a nurse is not required to determine whether a patient is to be deemed suicidal, her responsibility is great. One painful feature of many such cases is the way in which the nurse's good nature may be imposed upon. A nurse gave up a half holiday offering to take a patient for a cycle ride; the patient was better mounted, outrode the nurse uphill, and escaped on to the railway. Fortunately she was found and returned safely. A patient threw a cup of hot tea in a nurse's face and with the broken fragments of china seriously cut her throat. She eventually recovered. In the present case the nurse was attacked and overpowered. We must not overlook the fact when personal supervision is substituted for mechanical contrivances it throws great responsibility on the nursing profession. How often have nurses and doctors been deceived by plausible tales or tempted in giving liberty by skilful feigning of convalescence! On the other hand, how often the beginnings of improvement have been stimulated by the nurse interpreting instructions in a liberal, intelligent manner! Have we not often heard patients say that they would never have recovered but for the encouragement given by such and such a nurse? The newspaper account said nothing about the nurse in this case, but surely it illustrates forcibly the responsibility which rests on the nursing profession in this connexion.

In the practice of psychiatry there is constant anxiety with regard to suicidal patients. Familiarity does not loosen the subconscious strain. Although the majority of accidents occur unexpectedly and but rarely to patients who have been recently examined with care, nothing will entirely eliminate the danger. It is impossible to see sufficiently into the inner workings of the mind, and even if the immediate risk be correctly estimated how can future fears and impulses be foreseen? There is a certain type of patient, fortunately not common, who sooner or later will succeed in ending his life in spite of all precautions. The anxiety is not so much in regard to these, but in respect to the doubtful cases, and in those approaching convalescence.

The decision whether a patient must be treated as suicidal, the degree and kind of supervision necessary, what occupations are to be encouraged, and when increased liberty can be given—indeed, the decisions affecting the whole manner of life—inevitably involve great responsibility. Little do the public realise the wear and tear this means. Frequently risks are taken after mature consideration in the hope of awakening healthy interests, and then the position corresponds with that of a surgeon who undertakes a grave operation on the chance of saving life. How differently the public regard the two cases!

All interested in psychiatry welcome the fullest investigation when an accident occurs, the welfare of the insane patient is rightly the concern of the King and his representative, but it is very doubtful whether the English system of public inquiry serves any useful purpose, whilst the newspaper accounts give relatives needless anxiety. The Scottish procedure by private inquiry is preferable. Let carelessness and abuses be exposed, but let us avoid the pain and discouragement caused by needless publicity.

I am, Sir, yours faithfully,

Malton, Oct. 11th, 1926. BEDFORD PIERCE.

IRRADIATION AND CELL-DIVISION.

To the Editor of THE LANCET.

SIR,—In a leading article on this subject in your issue of Oct. 9th, doubt is cast on the correctness of the statement that dividing cells are more sensitive to radiation than growing cells. In support of this, mention is made of the work of Strangeways and Oakeley, who confirmed using in vitro cultures what had been previously observed by Albuti and Politzer with tumours, that an important action of radiation is to inhibit mitosis. Mottram, Scott, and Russ confirmed this, using a statistical method in the case of Jensen's rat sarcoma, and the results suggest that it is the growing period that suffers inhibition rather than that there is a block in the change over from growing to dividing phases. But these findings in no way negative the statement that dividing cells are killed more easily than growing cells. This has been observed by several workers, and Mottram has shown that in the case of the ova of ascaris, dividing ova are approximately eight times more sensitive than growing ova. Further, Strangeways and Hopwood have shown that cells radiated during mitosis complete the cell division in a normal manner.

All these findings are reconcilable, though perhaps difficult to expound. When a cell is radiated during mitosis then the mitosis is completed normally, the growing stage of the daughter cells is prolonged, and the onset of the following mitosis delayed. After a time an abnormal mitosis occurs, the cell may die and disintegrate without completing this cell division, or abnormal daughter cells may result which subsequently die. When a cell is radiated during the growing stage, similar effects occur, but they are much less marked; the delay in mitosis is less prolonged, the following mitoses and the resulting daughter cells are not so abnormal, and death of the cell less likely to occur; complete recovery may occur, but is very slow, abnormal cells persist for weeks, and the rate of growth retarded by the radiation may take months to return to normal.

This very shortly describes what appears to be the sequence of events in the life-history of cells following radiation. Detailed discussion of these changes is desirable; my aim in this letter has been to make a concise statement. Of course, the fact that dividing cells are more sensitive to radiation than growing cells does not explain the fact that rapidly growing tumours are especially sensitive to radiation; for the reason that when a tumour is radiated, even a rapidly growing one, only a very small proportion of the cells are undergoing mitosis during radiation. The explanation for this lies elsewhere.

I am, Sir, yours faithfully,

J. C. MOTTRAM.

The Radium Institute, London, W., Oct. 11th, 1926.

PREPAREDNESS AGAINST SMALL-POX.

To the Editor of THE LANCET.

SIR,—In view of the fatal cases of small-pox reported from Willesden and Lambeth, and of the further importation of the same type of infection as shown in a severe confluent case in Islington this week, may I make a strong appeal to your readers to help to make known the elements of small-pox diagnosis to every one of our colleagues in the profession? In 1913 I wrote: "It is essential to realise the mischief which may be done by unrecognised cases of small-pox. There is hardly any disease of which the prompt recognition is more important to the general community. Almost every outbreak in London in recent years has been started or propagated and prolonged by unrecognised cases."—"How to Diagnose Small-pox" (p. 1).

Our profession has made a remarkable response to those indications. Missed cases are strikingly fewer than they used to be, but for that very reason they are now all the more conspicuous. Our principal duty, I submit, at a time like the present, is to make

sure that we have done all in our power to make the necessary knowledge known. Speaking for myself, although something has been done, there is much more that I should like to have been able to do. This is the point. Every single qualified man in the Kingdom should have a knowledge of the simple ground-work of small-pox diagnosis in his hands and in his head. It is more imperative than a knowledge of the femoral artery.

We all know the anxiety and risk of being unprepared to meet a possible emergency; the risk of losing patient, reputation, and practice. That unpreparedness should never be allowed to continue if it can possibly be remedied. With this in view, I ask your permission again to mention two items especially. One, a booklet termed "Small-pox Notes for Medical Practitioners, with Hints on Diagnosis" (price 8*d.*). The other, a reprint of a post-graduate lecture entitled "The Accurate Diagnosis of Small-pox" (price 6*d.*). Both are obtainable from either the *Medical Officer* weekly journal, 36, Whitefriars-street, or from George Wareham, 1, Budge-row, Cannon-street, E.C. 4. To overcome the difficulty caused by an author having to mention his own works, and other difficulties in connexion with their distribution, their issue is being handed over to the Small-pox Clearance Voluntary Fund, of which for the time being I am hon. secretary. The main aim of this fund is the complete clearance of small-pox out of the country, that being a business-like and practical proposition.

Some 3000 practitioners have been provided with one or the other of the above-mentioned booklets so far, principally owing to the fact that many public authorities, on the recommendation of their responsible officers, have distributed copies to all the practitioners in their respective areas, an eminently reasonable proceeding considering the value of the public service rendered by practitioners in this field of work. And in many cases this precaution has been wisely taken *before* the appearance of small-pox. Reports show that such an issue is greatly appreciated. Practitioners are forewarned and forearmed. Their own confidence and standing are increased; the hands of the medical officers of health are strengthened; and generally speaking, there is a heightening of the efficiency of the whole anti-small-pox line which at the present time is the sole barrier standing between our people and the catastrophe of a small-pox epidemic.

So far as is known, small-pox has never gained a foothold in any area where the profession has been so equipped.—I am, Sir, yours faithfully,

W. McC. WANKLYN.

Luxemburg-gardens, Hammersmith, W., Oct. 11th, 1926.

ECONOMY IN IODINE.

To the Editor of THE LANCET.

SIR,—At a time such as the present when every possible effort has to be made to reduce waste and unnecessary expenditure of money or material the following small modification of a common practice may prove useful to your readers. The usual hospital practice of supplying tincture of iodine to dressing-rooms and wards is by means of an 8-oz. stoppered bottle. The tincture is applied either by means of a sponge or by gauze soaked either by direct pouring or by the very wasteful method of decantation into a small basin. If the iodine be put up in 4-oz. dropping-bottles, such as are used for bacteriological stains, it can be applied with far greater ease and accuracy. The amount of iodine which reaches the required spot is far greater and the waste is reduced to negligible proportions. Since using this method in certain ambulance rooms under my charge where the daily attendances for minor injuries are large, I have been enabled to reduce the expenditure on this single item by over 50 per cent. The saving in terms of money is considerable.—I am, Sir, yours faithfully,

Beeston, Notts, Oct. 8th, 1926. L. P. LOCKHART.

MILK DESIGNATIONS.

To the Editor of THE LANCET.

SIR,—I observe the correction of Mr. Miles, the secretary of the Certified Milk Producers' Association, in your last issue, but unless I am mistaken the very limited public which knows anything at all about the official special designations of milk has formed its own euphemisms, and calls "Grade A (Tuberculin Tested) Milk" "Grade A Certified Milk." Be that as it may, I have never been able to accept as of any real significance the Milk (Special Designations) Regulations. To my mind it is hopeless—quite hopeless—to expect the general public, for whose benefit the whole milk trade—producers and distributors alike—exists, even to commence to remember, much less to understand, the various grades set up in the regulations. These regulations stand condemned because they do not prohibit the sale of dangerous milk. They do not forbid the sale for human consumption of milk containing the bacillus of dung, nor the bacillus of tuberculosis.

I am, Sir, yours faithfully,

S. G. MOORE, M.D.,
M.O.H., Huddersfield.

Oct. 9th, 1926.

WANTED, AN APPENDIX.

To the Editor of THE LANCET.

SIR,—For the last four months I have been endeavouring to obtain a freshly excised appendix from a certain type of subject. I need an appendix which has been excised "in the cold" and which is, therefore, not particularly inflamed. I have been able to obtain a number of these from normal subjects from my own hospital; but I wish, in order to round off a piece of research, to obtain such an appendix excised from a person with a well-marked protein sensitisation; for example, from a hay-fever subject, a horse asthmatic, or one with a well-marked food idiosyncrasy. I think I am more likely to obtain this through some private practitioner than from the hospital theatre, because the practitioner knows more about the past history of his cases. It would be necessary to get into touch with such a practitioner say a week before the appendectomy, in order to verify the sensitisation and to make suitable arrangements for receiving the appendix. For example, it must be dropped quite fresh into Ringer solution through which a stream of oxygen passes, and it should be in my laboratory within half an hour of excision if possible.

I know this is asking a very great deal, but unless I can obtain such a specimen, or specimens, within the next two months, then several months of careful research work will have been spoilt. May I ask for your assistance in the matter?

I am, Sir, yours faithfully,

St. Mary's Hospital, Oct. 11th, 1926. J. FREEMAN.

THE ROYAL FAMILY AND YORKSHIRE HOSPITALS.—On Thursday in last week Princess Mary opened the new out-patient department of the Victoria Hospital for Sick Children at Hull, and made a tour of the wards. On Tuesday last the Prince of Wales laid the foundation-stone of the Queen Alexandra Memorial Wards of the new infirmary at Doncaster. The buildings will cost £300,000. The two enlargements which have been made in the last 20 years have proved to be inadequate.

WORK OF MANCHESTER HOSPITALS.—Manchester has had a Civic week from Oct. 2nd to Oct. 9th, and interesting accounts have been published of the various agencies for social service, including the medical charities of the city and hospitals in the neighbourhood, which form the largest group of hospitals outside London. The number of beds in these institutions is almost double the number available in Liverpool or Birmingham. In 1925, in Manchester, 42,000 cases from outside districts were treated. Only £110,000 were subscribed by the districts concerned. The new patients alone every day amount to 820, and each day over £1000 is needed to cover the cost of treatment. At the Royal Infirmary one accident case is attended to every 20 minutes. In 1920 the daily average was 50. In 1925 there were 29,347, a daily average of 75.

MEDICAL ARTICLES IN THE GENERAL PRESS.

AT a meeting of the St. Pancras Division of the B.M.A. on Tuesday last, Oct. 12th, Sir HUMPHRY ROLLESTON took the chair, and introduced a discussion on the

Aims and Methods of Health Education,

arising out of an address delivered to the meeting by Sir Thomas Horder (vide p. 795). The object of the meeting, he said, was to facilitate exchange of private views on the relations of the medical profession with the general press. It was desirable, in his opinion, that the public should know as much as possible about preventive medicine, always provided that curative medicine remained in qualified hands. He did not agree that instruction on medical matters through the lay press was of no use. A writer with the necessary qualifications, medical and journalistic, could do valuable service. It must be agreed, however, that advertising by this means was in the interests neither of the profession nor the public. It was often desirable that someone with authority should sound a note of warning. The object of this discussion was to decide where the line was to be drawn between the warning of one possessing authority and the advertisement of one without it.

Sir THOMAS HORDER then delivered his address, the points and humour of which were appreciated by a good audience, and concluded in order to give a direction for discussion by proposing a resolution :—

"That the education of the public in health and in the prevention of disease being of national importance, the dissemination of views on health topics should be encouraged. Actual medical instruction might well be controlled by a representative body and editors should not ask men in private medical practice to write articles under their own name."

Mr. MCADAM ECCLES said that all agreed that the public should be instructed in health matters, but anything published should have as its first and only object the good of the public. Anything savouring in the least of self-advantage must be banned, and preferably by the lay press itself. It might be possible to arrange a meeting of representative editors of the public press and to determine that this scrutiny of health articles should be carried out for the good of the land and the people. A burning question was whether articles that were truthful, sane, and useful should be signed. The best method was to print the degrees without the name ; these were what, for the responsible editor, gave real prestige to the article.

Dr. GRAHAM LITTLE mentioned a personal experience in which the press had reported as a serious opinion a joke which he had made at a medical meeting, instancing the episode as an illustration of how little the lay press discriminated in publishing medical matter. If the expert would not address the public the inexpert would, and much harm was done to the profession by the rubbish that was published nowadays. He suggested that they should test the receptivity of the press and public by giving them serious articles to read, written by acceptable authorities. He feared that neither were yet ready for such articles, but the profession must nevertheless try to supply them.

Dr. ALFRED COX wished to make two points, one of which referred to the lay press and the other to certain members of the medical profession. The first was that the press would not succeed in their laudable desire of raising the standards of their own profession if they continued to trample on the traditions of others. He wished to ask them if they did not think that the plea of the medical profession, that their traditions should be respected, had something in it. His second point was that medical men could not expect the lay press to believe that medical traditions existed if they themselves did not manifest adherence to them. He quoted the following words from Sir William Osler's "Æquanimitas" :—

"In the life of every successful physician there comes the temptation to toy with the Delilah of the press. There are times when she may be courted with satisfaction, but beware ! Sooner or later she is sure to play the harlot and she has left many a man shorn of his strength—the confidence of his professional brethren."

Mr. E. B. TURNER, seconding the resolution, said that he had just emerged from a maelstrom of health weeks, and it had been almost pathetic to see the eagerness of the public to learn of health matters that they might be helped to prevent disease and preserve life. Should there be no control there would be great danger that editorial staffs might pick and choose those whom they considered suitable to educate the public. There was no question that health propaganda could be carried on without any personal advertisement whatsoever if the individuals who undertook the work so chose. He hoped that they meant to do so and to remember what their profession was, that they might do nothing to lower its proud position to the level of an advertising trade.

Miss C. A. MORTLOCK-BROWN spoke of the difficulty of serving two masters, medicine and literature.

Colonel HOWARD MUMMERY said that only the middle part of the resolution could arouse any difference of opinion or problem. How could the profession set up a representative body to which the public as a whole would listen and which yet would exercise some control ? No organisation probably filled the bill completely at present, so that there was reason for the formation of an ad hoc body.

Sir CHARLES GORDON-WATSON said that the public should look to their general practitioner for their advice on health and pay his fee for it and not a penny to the daily paper. The lay press was responsible for the demand for signed articles ; the public did not want the information ; if the press wanted it let them get the best and get it under authority.

Dr. SCOTT STEVENSON said that editors and medical journalists would not stand such a committee. He had written many articles for the press and had never had one refused because it was unsigned. Leader-writers did not sign political articles ; why should the medical writer ? He always skipped a signed article because he knew that it was one which would not carry sufficient weight to justify publication without the signature.

Prof. W. E. DIXON said that the proposed method was an impossible one ; nobody would read the made-up articles of a committee. The country prided itself on a free press, and on encouraging writers with some virility of style ; and their abolition would be a loss and no gain. No editor would accept the platitudes laid down by any medical society.

Prof. V. H. MOTTRAM said that it was most important for every man to have an overhaul at some period in his life so that he might know what his own normal was, and for the public to be educated in such subjects as the early symptoms of tuberculosis.

The resolution was then passed by the meeting without a dissentient vote.

Sir THOMAS HORDER, in replying, said that he had hardly mentioned the difficulties of the whole question nor was he optimistic that his suggestions would be popular. He was, however, speaking to doctors and not to the press, whom he could not venture to instruct how to carry on their profession. The views of the press on what constituted news being as they were, they could not be expected to accept forthwith the maxims put forward by a body such as he suggested. When the effect of the resolution had taken shape it might be said that there was a body who would provide authoritative material on health matters if the press wanted it. There was the test ; if they did not want it, they would show that they wanted, not to instruct the public, but to print the titles of eminent medical writers. Medical men did not know where they stood, and wished to do so ; they were still asked for their photographs and for picturesque views. His resolution would do no harm, but he had received no constructive suggestions from the meeting.

Medical News.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the monthly meeting of the Faculty, held on Oct. 4th, the following were admitted (after examination) as Fellows :—

Adam Barr, Andrew Allan Bell, Joseph Alexander Bingham, Donald M'Kenzie Black, Andrew Duffield Blakely, John Miller Chrystie, Thomas Hall James Douglas, Alexander Garrow, Zafar Husian Jafri, William Douglas MacFarlane, Edwin Gordon Mackie, Thomas Kay MacLachlan, William M'William, George Thomson Mowat, William Alexander Sewell, Harold Edward Whittingham, John Miller Young, and Roy Frew Young.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The second of the series of lectures on Emergencies in Medicine and Surgery will be delivered by Mr. Joseph Adams on Acute Appendicitis, on Thursday, Oct. 21st, at 5 P.M., in the lecture hall of the Medical Society of London, 11, Chandos-street, W. A special lecture-demonstration on cataract will be given by Mr. A. Caddy at the Royal Westminster Ophthalmic Hospital, at 5 P.M., on the same day. Both the lecture and demonstration will be open to members of the medical profession without fee. The following courses have been arranged: Nov. 1st to 13th, a course in medicine, surgery, and the specialties for general practitioners, at the Hampstead General Hospital; Nov. 1st to 30th, a course in venereal disease at the London Lock Hospital; Nov. 15th to Dec. 4th, a course in gynæcology at the Royal Waterloo Hospital; Nov. 15th to Dec. 11th, a course in dermatology, including pathology if desired, at St. John's Hospital; Nov. 22nd to Dec. 18th, a course in neurology at the West End Hospital for Nervous Diseases (late afternoons); Nov. 29th to Dec. 11th, a course in diseases of the chest at the Victoria Park Hospital; Nov. 22nd to 27th, a course in proctology at St. Mark's Hospital, and from the same date a course for general practitioners at the London Temperance Hospital. Copies of all syllabuses, of the General Course Programme of the Fellowship, and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

CHADWICK PUBLIC LECTURES.—On Tuesday and Wednesday, Oct. 19th and 20th, at 5 and 8 P.M. respectively, in the Barnes Hall of the Royal Society of Medicine, 1, Wimpole-street, London, W., lectures on the Development and Present State of Public Health in Germany will be given by Prof. R. Abel, Director of the Institute of Hygiene at Jena University. Sir William Collins will take the chair at the first lecture and Sir Arthur Newsholme at the second. Admission to these and other lectures will be free without ticket. At Southampton University College on Monday evening, Oct. 25th, Mr. H. T. Calvert, D.Sc., of the Ministry of Health, will speak on the Activated Sludge Process of Sewage Treatment; Sir Robert Greig, Chairman of the Board of Agriculture for Scotland, will lecture on Deficiency Diseases of Animals in Relation to Public Health at the Royal Society of Arts on Monday, Nov. 1st, at 8 P.M.; and Sir Henry Gauvain, medical superintendent of Lord Mayor Treloar Cripples' Hospital and College, will give an address on Dec. 2nd at the house of the Royal Society of Medicine on Sun, Sea, and Open Air in Relation to Health and the Prevention of Disease. Other arrangements include a lecture at Sheffield by Mr. H. E. Stilgoe, chief engineer of the Metropolitan Water Board, on Nov. 22nd, on Water-supply and its Relation to Public Health, and one by Mr. William A. Robson on Legal Conceptions of Public Health at the Royal Sanitary Institute on Monday, Dec. 13th, at 8 P.M. Particulars of the lectures may be had from Mrs. Aubrey Richardson at 13, Great George-street, Westminster.

FLEET-STREET WEEK FOR BART.'S.—"Fleet-street" has been holding a "week" for the benefit of St. Bartholomew's Hospital. It began officially on Sunday, but there was a popular opening on Saturday in the shape of a long procession of decorated vehicles from the Victoria Embankment, through Queen Victoria-street, into the heart of the City and back by Holborn Viaduct, Fetter-lane, and Fleet-street to New Bridge-street. The carriages bore many topical representations, including some Bart.'s men in bed nursing "carnival babies." The fuselage and engine of the aeroplane in which Sir Alan Cobham flew to Australia and back were mounted upon one of the vehicles. It is hoped to raise £20,000 by the week, and much money was given by the crowds on Saturday. On Tuesday an auction sale at Bush House was opened by the Lady Mayoress of London, and an Empire concert was given in the Kingsway Hall, attended by the Maori football team. The "week" closes to-day (Saturday).

HARVEIAN SOCIETY OF LONDON.—Owing to the further generosity of Mr. George Buckston Browne, the sum of £1000 has been added to the Memorial Prize Fund which bears his name. The council of the society will, therefore, in the future be in a position to give more valuable prizes for successful essays.

HUNTERIAN SOCIETY.—The first dinner meeting of this society will be held at Simpson's Restaurant, 2 and 3, Bird-in-Hand-court, 77, Poultry, Cheapside, on Monday, Oct. 18th, at 7.30 P.M. At about 8.30 P.M. Mr. A. E. Mortimer Woolf will deliver a presidential address on Pain.

INCORPORATED ASSOCIATION OF HOSPITAL OFFICERS. Sir Arthur Stanley will deliver a presidential address at the headquarters of the association, 28, Bedford-square, London, W.C. 1, on Wednesday, Oct. 27th, at 7 P.M.

TAVISTOCK CLINIC MATINÉE.—A special matinée is to be given in aid of the Tavistock Clinic on Friday, Oct. 22nd, at 2.30 P.M., at His Majesty's Theatre, Haymarket, London. The clinic was founded in 1920 to provide treatment for war sufferers and others who are unable to pay specialists' fees. Tickets for the performance may be had at the theatre or from the clinic, 51, Tavistock-square, W.C.

EUGENICS EDUCATION SOCIETY.—The first meeting of the session was held on Wednesday, Oct. 13th, at 8.30 P.M., when Major Leonard Darwin gave a presidential address on Anthropological Studies of Children. There will be three other lectures this year, on Nov. 10th and 24th, and Dec. 8th, by Prof. C. E. Spearman, Mrs. Sturge Gretton, and Prof. A. M. Carr-Saunders. The society's address is 20, Grosvenor-gardens, London, S.W. 1.

MEMORIAL TO A DOCTOR.—A tablet has been placed in the Banbury Infirmary in memory of Dr. Evan Christopher Pritchard, and in recognition of his valuable services to Banbury and neighbourhood and to the Banbury Infirmary. A cot in the children's ward has also been dedicated to the doctor's memory and has been endowed in perpetuity by money contributed by 450 subscribers.

POST-GRADUATE COURSES AT VIENNA.—The syllabus of post-graduate lectures in German, arranged by the Medical Faculty of the University of Vienna, may be had free of charge from the Kursbüro der Wiener Medizinischen Fakultät Wien VIII, Schlösselgasse 22. Information about board and lodging is also given, but applicants by letter are asked to enclose an international stamp coupon for the reply. The arrangements include international finishing courses, lasting two weeks each, and held four times a year (November, February, June, and September), which will deal with progress in the special branches of medicine.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The annual general meeting of this society will be held at the Palace Hotel, Welbeck-street, Cavendish-square, London, W., to-day (Friday, Oct. 15th), at 4 P.M. Amongst activities proposed for the coming year are the preparation and presentation of a Bill to Parliament, and the presentation of a direct petition to the Privy Council. At a meeting on Sept. 24th the council of the society decided to nominate one or two women to join the council. The hon. secretary of the society is Mr. Sidney C. Lawrence, 106, Richmond Park-road, Winton, Bournemouth, Hants.

PORT HEALTH OFFICERS AT LIVERPOOL.—Medical officers of the North Sea and Baltic ports, who, during the past few months, have been making a tour of inspection under the auspices of the League of Nations, visited Liverpool on Oct. 7th. They visited the Government Wool Disinfecting Station, and the Seamen's Dispensary where tropical, venereal, and other diseases are treated. They were also shown how the inspection of ships' rats suspected of carrying bubonic plague is carried out in the city laboratories. About 10,000 rats are examined each year. The visitors, together with the Liverpool consuls of the countries they represented, were the guests of the Lord Mayor at the Town Hall.

THE NEW PROCEDURE IN CORONERS' COURTS.—At an adjourned inquiry held on Oct. 5th at Alderley Edge into the circumstances of the death of a girl of 20, Mr. H. C. Yates, the East Cheshire coroner, said that formerly, when a person died from injuries inflicted upon him or her by some other person, and that person was in custody charged with the offence, the case was gone into fully, both at the police-court and by the coroner. This duplication of evidence had now come to an end. The coroner stated that he had communicated the course he proposed to adopt in this case to the Director of Public Prosecutions, and with his approval was only going to call three witnesses, and would adjourn the inquiry until after the assizes had been held.

HOSPITAL DINNERS.—The annual dinner of old students of *St. Thomas's Hospital* will be held on Friday, Oct. 29th, at 7 for 7.30 P.M., at the Hotel Victoria, Northumberland-avenue. Dr. R. Percy Smith will take the chair.

The annual dinner of past and present students of *University College Hospital* will be held at the Hotel Cecil on Wednesday, Oct. 27th, at 7 for 7.30 P.M., Dr. Philip D. Turner in the chair. Tickets may be had, before Oct. 25th, from Mr. Gwynne Williams or Dr. F. M. R. Walshe, at the Medical School.

NEW SUSSEX HOSPITAL FOR WOMEN AND CHILDREN. Although this Brighton hospital was only opened in 1921, the demand on its accommodation became so heavy that extension was soon needed. Thanks to a promise of £1000 by Mr. Bernhard Baron, supplementing the result of the governors' appeal for funds for building a new wing, the extension will now be put in hand. The sum of £600 has been given by a lady, who wants to remain anonymous, for the purchase of radium for cancer research work. The hospital is entirely staffed by women doctors.

NEW MATERNITY HOSPITAL AT LIVERPOOL.—Although the activities of this new maternity hospital have been in full swing for some time, it was only on Thursday, Sept. 30th, that the formal opening took place. This ceremony was performed by Miss Hartley, to the generosity of whose father, the late Sir William Hartley, the institution owes so much. Previously, however, there had been a large public meeting, presided over by the Lord Mayor, at which Sir George Newman and Dame Mary Scharlieb were present. The former spoke of the great mortality still attendant year by year upon childbirth. He envisaged the new maternity hospital as a training ground for doctors and nurses which would go far towards reducing such risks. The latter referred to the fact that during the last year 325 women had had to be turned away, to sink or swim, for lack of accommodation. This was not worthy of a great and progressive city like Liverpool, and she trusted that very speedily the full complement of 100 beds would be available.

THE LATE DR. F. H. TETLEY.—Dr. Frederick Harrison Tetley, who died at Pool on Oct. 4th, was the third son of the late Mr. George C. Tetley, of Bradford. He studied at the University of Edinburgh and after qualifying as L.R.C.P. & S. Edin. in 1877 held the appointment of house physician at Glasgow Royal Infirmary. Settling in practice at Keighley, he became honorary surgeon to the Victoria Hospital, and subsequently at Bungay in Suffolk, was honorary consulting surgeon to the All Hallows' Hospital, Ditchingham. About 25 years ago he relinquished general practice and wintered each year in Las Palmas, where he was honorary surgeon to the Victoria Hospital for Seamen. On the outbreak of the war Dr. Tetley was appointed surgeon to the Guards at Caterham, and later physician to the City of London War Hospital, Epsom. He was also chairman of various medical boards, and at the close of the war acted as chairman of the pensions boards at Plymouth and other places.

LEAMINGTON SPA.—On Oct. 9th Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, opened the enlarged pump-room and baths at Leamington in the presence of a number of medical guests. British spas, he said, would bear comparison, certainly in equipment, with any of their foreign rivals, and spa treatment should be made available under proper conditions to the greatest possible number of people—the rich and the worker alike. Within the last few days an important step had been taken by the National Conference of Friendly Societies at their annual gathering. They were asking the Ministry of Health to include spa treatment as one of the additional benefits under the National Insurance Scheme. The Federation of British Spas stated that some 30,000 cases might be treated at British spas up and down the country, and he could promise that the Ministry of Health would give the most careful and sympathetic consideration to the suggestion that spa treatment should be recognised as an additional benefit. He believed that this would do a great deal, not only for the spas but to check and counteract the ravages of rheumatism by making the spas available to a far larger portion of the community. A vote of thanks to Sir Kingsley Wood was proposed by Sir William Smith, and seconded by Dr. R. Fortescue Fox, who said that he had long looked forward to the time when the State would recognise the spas as a national asset. The effects of medicinal waters and physical treatment required much more careful study than they had received. The subject was calling out for research and modern methods made this possible. At Leamington, he thought, such investigation might well be carried on.

SMALL-POX IN LONDON.—Dr. Clarke Trotter, medical officer of health for Islington, informs us that a patient who had been staying in Paris from Sept. 11th to 24th was admitted to the Royal Northern Hospital, Holloway, on Thursday, Oct. 7th, and was isolated. On Monday, Oct. 11th, the diagnosis of small-pox was confirmed. Dr. Trotter believes that the infection was probably contracted between Sept. 22nd and 24th. The patient was staying at a hotel in the 9th arrondissement of Paris. As we reported last week (THE LANCET, p. 781) cases of small-pox contracted at Paris have been reported at Willesden, but the hotels were not the same, nor is there any known connexion between them. Small-pox is prevalent in Paris, but Dr. Trotter states that it is comparatively mild in character, whereas the new London cases are not. Fortunately, he says, the case admitted to the Royal Northern Hospital was isolated in good time.

BRITISH EMPIRE CANCER CAMPAIGN.—A quarterly meeting of the Grand Council was held on Oct. 12th, Lord Cave presiding. Sir Richard Garton, chairman of the Finance Committee, commented upon the heavy commitments of the Campaign and the ever-increasing calls upon the funds, occasioned by the increase in all directions in the number of research investigations. Mr. J. P. Lockhart-Mummery, chairman of the Executive Committee, informed the Grand Council that the visits of members of the Intelligence Committee to the principal American and Continental cancer research laboratories would be completed shortly, and their reports upon the most recent work on cancer research outside the British Empire would be laid before the Grand Council. Lieut.-General Sir John Goodwin reported that there would shortly be 19 county committees working in aid of local research centres or on the work of the general organisation of the Campaign. Sir William Milligan and Sir Robert Jones were unanimously elected to membership of the Grand Council. Prof. R. T. Leiper, F.R.S., was appointed a member of the Scientific Advisory Committee of the Campaign in place of the late Sir William Leishman.

DONATIONS AND BEQUESTS.—Mr. Samuel Turner, of West Kirby, who left estate of the gross value of £44,075, on the death of his wife, left £750 to the Hoylake and West Kirby Cottage Hospital and other bequests totalling about £9000. The ultimate residue of his property, which will amount to nearly £30,000, he left to the University of Liverpool, to be applied as the University authorities in their discretion may think fit for the furtherance and advancement of medical research into the diseases of phthisis and cancer and any kindred diseases.—Mr. Joseph Augustin Bellinger, of Sidmouth, Devon, retired photographer, who left £5542, bequeathed, subject to his wife's life interest: £100 to the London Hospital, "in grateful recognition of benefit received by me in 1854"; £100 to St. Bartholomew's Hospital, "in similar grateful recognition of benefit received by me in 1868"; £100 to the Devon and Exeter Eye Infirmary, "in similar grateful recognition of benefit received by me in 1888"; £100 to Charing Cross Hospital, "in similar recognition of benefit received by me in 1875." There were other legacies to Devon hospitals, and the ultimate residue of the property is left to the London Hospital, St. Bartholomew's Hospital, Charing Cross Hospital, the Devon and Exeter Eye Infirmary, Sidmouth Cottage Hospital, and the Devon and Exeter Hospital.—The late Mr. Pryce Thomas Williams, J.P., of Rhos-on-Sea, Colwyn Bay, left £1000 to Colwyn Bay Cottage Hospital and £500 to hospitals in Liverpool.—By the will of the late Mr. Robert William Hatfield, of Fern Bank, Malton, bequeathed on the death of his wife £1000 to the Malton Cottage Hospital.—Mrs. Margaret Hamilton Hamilton-Fellows, of Worplesdon, Surrey, bequeathed £1500 to the Boscombe and West Hampshire Hospital, to endow a bed in her memory; £1000 to the British Home and Hospital for Incurables, Streatham, for the same purpose; and £1000 each to the Royal Waterloo Hospital for Women and Children, the Royal Society for the Prevention of Cruelty to Animals, Dr. Barnardo's Homes, the Royal Surrey County Hospital, Guildford, St. Dunstan's Home for Blinded Soldiers, Sailors, and Airmen, and the Royal Ophthalmic Hospital. The testatrix also left her freehold house, 12, Cambridge-road, Battersea, to the National Society for Day Nurseries, and endowed the society with an annuity of £250, free of death duties, for the upkeep of the same as a creche.—Sir John Walker Craig, K.C., of Hove, Sussex, Recorder of Belfast, left £1000 to the Royal Victoria Hospital, Belfast, and the reversion of a further bequest to that hospital.—Mrs. Elizabeth Lavinia Cheshire, Handsworth, Birmingham, who left estate of the value of £29,959, left £3000 to her sister-in-law for life, and the residue of the property is left between the General Hospital, Birmingham; the Queen's Hospital, Birmingham; the Birmingham and Midland Free Hospital for Sick Children; the Birmingham and Midland Hospital for Women; and the Birmingham Royal Institution for the Blind.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MONDAY, Oct. 18th.—8.30 P.M., SOCIAL EVENING. Fellows, Members of Sections, and their friends will be received in the Library by the President and Lady Berry. 9.30 P.M., Sir Arthur Keith: Address on John Bull: a Study in Anthropology (with illustrations).
TUESDAY.—5.30 P.M., Ballot for election to the Fellowship. 8.30 P.M., PATHOLOGY. Presidential Address by Dr. J. McIntosh.
WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Mr. Walter G. Spencer: Review of the "Proceedings" of the Section. Short Communication: Dr. LeRoy Crummer (Omaha Univ.): The Copperplates of Raynalde and Geminus. 8.30 P.M., SURGERY. Mr. Warren Low: Surgery and the Workmen's Compensation Act, to be followed by a discussion.
THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.), Cases: Dr. F. Parkes Weber: Recklinghausen's Disease, Pigmentation of the Thigh, and Hypoplasia (Aplasia) Pilorum Moniliformis. Dr. G. B. Dowling: Lichen Nitidus: Confluent type, and Syphilitic Macular Atrophy. Dr. Haldin-Davis: Pigmentation of Unknown Origin. Prof. C. Rasch (Copenhagen): Some Historical and Clinical Remarks on the Effect of Light on the Skin and Skin Diseases.
FRIDAY.—5 P.M., STUDY OF DISEASE IN CHILDREN. (Cases at 4.30 P.M.) Clinical Meeting. 8 P.M., EPIDEMIOLOGY AND STATE MEDICINE. Dr. S. Monckton Copeman: Immunisation Methods in Infectious Diseases.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.
THURSDAY, Oct. 21st.—7.45 P.M., Opening Meeting. The chair will be taken at 8.15 P.M., and a paper will be read by Prof. N. Hamilton Fairley (Haffkine Institute, Bombay) on Studies in the Chemotherapy and Immunity Reactions of Schistosomiasis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
MONDAY, Oct. 18th.—5 P.M., Mr. C. E. Shattock: Surgical Conditions of Lymphatic Gland.
FRIDAY.—5 P.M., Sir Arthur Keith: Anatomy of the Sacro-iliac Region and its Application to Practice. (Demonstrations open to advanced students and medical practitioners.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Oct. 18th. to SATURDAY, Oct. 23rd.—FELLOWSHIP OF MEDICINE (Special Lecture), Medical Society of London, 11, Chandos-street, Cavendish-square, W., Thurs., Oct. 21st, Mr. Joseph E. Adams: Acute Appendicitis.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross, W.C., Thurs., Oct. 21st, 5 P.M., Mr. A. Caddy: Special Lecture-Demonstration on Cataract.—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C. Intensive course in clinical laryngology, rhinology, and otology Operative class also.—COMBINED COURSE IN DISEASES OF CHILDREN, Paddington Green, Victoria Hospital and Children's Clinic. All-day course.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Post-graduate course in gynæcology. Operations, demonstrations, and lectures.—ST. PETER'S HOSPITAL, Henrietta-street, W.C. Clinical course in Genito-Urinary Diseases, including cystoscopies and formal lectures dealing with various aspects.—LONDON SCHOOL OF TROPICAL MEDICINE, Endsleigh-gardens, W.C., Tues. and Thurs., 2 P.M., Clinical Demonstration. Further information from the Secretary of the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY. Oct. 18th.—2 P.M., Medical Cases in the Wards. 2.30 P.M. to 5 P.M., Medical, Surgical and Gynæcological Clinics. Operations.
TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.
WEDNESDAY.—2.30 P.M. to 5 P.M., Medical Skin and Eye Clinics. Operations.
THURSDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, and Ear Nose, and Throat Clinics. Operations.
FRIDAY.—2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
On Tues., Oct. 19th, and Frid., Oct. 22nd, at 2.30 P.M., there will be special demonstrations of Medical Cases by Dr. L. R. Yealland and Dr. F. G. Crookshank respectively.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Oct. 19th.—5 P.M., Dr. H. W. Barber: Bacteriology and Mycology.
THURSDAY.—5 P.M., Dr. J. T. Ingram: Pathology Demonstration.

NATIONAL HOSPITAL, Queen-square, Bloomsbury, W.C.
MONDAY, Oct. 18th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: Pontine and Medullary Syndromes.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Bernard Hart: The Psychoneuroses.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Riddoch: Some Sequelæ of Encephalitis Lethargica.
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Collier: Lesions of the Mesencephalon.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street.
THURSDAY, Oct. 21st.—4 P.M., Dr. Nabarro: Meningitis in Children.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Oct. 19th.—4.15 P.M., Mr. P. R. Wrigley: Common Lesions of the Rectum.
FRIDAY.—4.15 P.M., Mr. Wilson H. Hey: Mammary Cancer.

ANCOATS HOSPITAL POST-GRADUATE COURSE.
THURSDAY, Oct. 21st.—4.15 P.M., Mr. Harry Platt: Treatment of Common Injuries.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, Oct. 15th.—3.30 P.M., at the Royal Infirmary: Dr. Brockman: Conditions Simulating the Acute Abdomen.

ST. MARGARET'S HOSPITAL FOR WOMEN, Acomb-street, Whitworth Park, Manchester.
WEDNESDAY, Oct. 20th.—4 P.M., Dr. Howard Buck: The Acute Abdomen.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.
TUESDAY, Oct. 19th.—4 P.M., Sir Humphry Rolleston: High Blood Pressure from the Clinical Aspect. Discussion to be opened by Dr. James Orr.

Appointments.

EAVES, ELIZABETH C., M.D., B.S. Lond., has been appointed Honorary Consulting Neuropathologist, South Yorkshire Mental Hospital, Sheffield.

M'DANIEL, E., M.D., B.Ch. Belf., School Medical Officer, County Tyrone.

RAMAGE, J. H., M.B., Ch.B. Glasg., Medical Officer for Western District of Neilston.

Oldham Royal Infirmary: MCGOWAN, J. S., M.D., B.S. Lond., Honorary Consulting Surgeon; FORT, H. M., M.B., Ch.B. Manch., Honorary Acting Surgeon; BROOME, F. C. S., M.B., B.S. Lond., Honorary Assistant Surgeon.

Royal Alexandra Infirmary, Paisley: M'ARTHUR J. C., M.B., Ch.B. Glasg., Senior Resident House Physician; AULD, W. J. C., M.B., Ch.B. Glasg., Resident House Physician; HILL, J., M.B., Ch.B. Glasg., and M'NEIL, Ian H., House Surgeons.

University of Sheffield: BLAKELOCK, J. H., M.B., Ch.B. Sheff., Assistant Bacteriologist.

Certifying Surgeons under the Factory and Workshop Acts: SALMOND, J. R., M.B., Ch.B. Belf. (Measham, Leicester); MCCONCHIE, J. F., M.B., Ch.B. Edin. (Wolsingham, Durham); GRIEVE, C. B., M.B., Ch.B. Edin. (Falkland, Fife); COLLIE, A. E., L.M.S.S.A. (Newport, Isle of Wight).

Vacancies.

For further information refer to the advertisement columns.

Barrow-in-Furness, North Lonsdale Hospital.—H.S. £130.
Barry Urban District Council, Accident and Surgical Hospital.—H.S. At rate of £200.
Bethlem Hospital, Lambeth-road, S.E.—Non.-Res. H.P. £25 per quarter.
Brighton, New Sussex Hospital for Women and Children.—Hon. Clin. Asst.
Bristol Mental Hospital, Fishponds.—Third Asst. M.O. £350.
Cambridge, Addenbrooke's Hospital.—Electrical and X Ray Dept. Asst. P.
Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100.
Cardiff Royal Infirmary.—Ophth. H.S.
Central London Ophthalmic Hospital, Judd-street, W.C.—Asst. Surg.
Chichester, West Sussex County Mental Hospital.—Med. Supt. £900.
Douglas, Isle of Man, Noble's Hospital.—Res. H.S. £175.
East London Hospital for Children and Disp. for Women, Shadwell, E.—Res. M.O. £200. H.P. and Cas. O. At rate of £125.
Great Yarmouth General Hospital.—H.S. £150.
Hospital for Sick Children, Great Ormond-street, W.C.—Bio Chemist. £600.
Infants Hospital, Vincent-square, Westminster.—Pathologist.
Ipswich, East Suffolk and Ipswich Hospital.—Res. Surg. O., &c. £300.
Lancashire Education Committee, Edge Hill Training College, Liverpool.—Visiting Med. O. 100 guineas.
Lancaster County Mental Hospital.—Med. Supt. £800.
Leeds, Jewish Herzl Moser Hospital, Leopold-street.—Res. M.O. £50.
Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Asst. Cas. O. At rate of £100.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Out-patient O. £150.
Macclesfield General Infirmary.—Second H.S. £150.

Metropolitan Hospital, Kingsland-road, E.—Sen. H.P., Sen. H.S., Jun. H.P., Jun. H.S., and two Cas. O.'s. All at rate of £100.
Otago Hospital Board, Dunedin, N.Z.—Med. Supt. £1000.
Otago University and Dunedin Hospital, New Zealand.—Medical Tutor and Sen. Res. M.O. Also Sen. Res. Surg. O. Each £400.
Plymouth, Royal Eye Infirmary.—Hon. S.
Portsmouth Royal Hospital.—Third H.S. and Cas. O. At rate of £150 and £100 respectively.
Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Cas. O. At rate of £100.
Rochester, St. Bartholomew's Hospital.—Third Res. M.O. At rate of £200.
Roehampton, Ministry of Pensions Hospital, Queen Mary's.—Consulting S. £400.
Royal Northern Hospital, Holloway, N.—H.S. and H.P. Each at rate of £70.
St. Marylebone General Dispensary, 30, Marylebone-lane, W.—Hon. S. to Ear, Nose and Throat Dept.
Salisbury General Infirmary—H.S. £150.
Stamford, Rutland and General Infirmary.—H.S. £200.
The Chief Inspector of Factories, Home Office, S.W., announces vacant appointments for Certifying Factory Surgeons at Shaw (Lancs.), and Eyam, (Derbyshire).

Births, Marriages, and Deaths.

MARRIAGES.

BENNET—TANNER.—On Oct. 11th, 1926, at St. Matthew's Parish Church, Edinburgh, by the Rev. F. H. Martin, B.D., Captain John Bennet, M.B., Royal Army Medical Corps, youngest son of Mr. and Mrs. J. R. Bennet, Maxwelltown, to Margaret Scott, youngest daughter of the late Samuel Tanner, Plewlands, Edinburgh, and Hillwoods Mains, Ratho, and of Mrs. Tanner, 14, Montpelier Park, Edinburgh.
DOGGART—BLACK.—On Oct. 7th, at Succoth-place, Edinburgh, James Macdonald Doggart, B.A., of St. Andrews, to A. McCaig Black, M.B., Ch.B., daughter of the late Hugh Black, Rothesay.
DULAKE—ROBERTSON.—On Oct. 7th, at St. Saviour's, Hampstead, Lawrence Dulake, M.B., B.S., to Nina Robertson, M.B., B.S., D.O.M.S., third daughter of Mr. and Mrs. C. Kay Robertson, of Hampstead.
GRIMMER—SELWYN.—On Oct. 7th, at Holy Trinity Church, St. Nicholas-road, S.W., George Kerr Grimmer, B.A., M.D., F.R.C.S.E., to Lilian Florence Nash Selwyn, widow of George Alexander Selwyn, Boundaries-mansions, S.W.
MACKINNON—BACKLER.—On Oct. 7th, at St. Marylebone Parish Church, Dr. Colin Campbell Mackinnon, M.R.C.S., L.R.C.P., to Ruby Jessie, eldest daughter of Mr. and Mrs. Alfred J. Backler, of Linton, Cambs.
PEACOCK—WARENGHEM.—On Oct. 7th, at St. Maurice de Becon, Paris, Philip Redington Peacock, M.B., son of Mr. and Mrs. F. G. Peacock, Stormont-road, Highgate, to Andrée, daughter of the late M. L. L. Warenghem and Mme. Warenghem, Becon, Asnieres.
PETRIE—WILLIAMS.—On Oct. 2nd, at Kew Church, A. A. W. Petrie, M.D., to Joyce Victoria, eldest daughter of the late A. E. Williams, Ceylon Civil Service, and Mrs. Williams. Kew, Surrey.

DEATHS.

LOWSON.—On Oct. 8th, Major Charles Stewart Lowson, M.B., C.M., I.M.S. (retd.), of Maybury Mansions, W.
MARRAT.—At a nursing home, Woking (of pneumonia), Constance Muriel (née Willis), M.R.C.S., L.R.C.P., B.S. Lond., in her 30th year. Also Barbara Jean, daughter of the above, aged one day.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 2ND, 1926.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 96 (last week 121); scarlet fever, 1715; diphtheria, 1011; enteric fever, 163; pneumonia, 510; puerperal fever, 44; cerebro-spinal fever, 6; acute poliomyelitis, 65; acute polio-encephalitis, 3; encephalitis lethargica, 44; continued fever, 1; dysentery, 10; ophthalmia neonatorum, 140: puerperal pyrexia, 23. There were no cases of cholera, plague, or typhus fever notified during the week. Puerperal pyrexia became a notifiable disease on Oct. 1st and it is now obligatory on the accoucheur to report under this heading any febrile condition occurring in a woman within 21 days after childbirth or miscarriage in which a temperature of 100·4° F. (38° C.) or more has been sustained during a period of 24 hours or has recurred during that period (see THE LANCET, August 21st, p. 404). The 23 cases shown in the return were notified during the first two days of the present month.

Deaths.—In the aggregate of great towns, including London, there were 2 (0) deaths from small-pox, 2 (0) from enteric fever, 5 (0) from measles, 3 (0) from scarlet fever, 25 (4) from whooping-cough, 36 (11) from diphtheria, 246 (63) from diarrhœa and enteritis under 2 years, and 32 (7) from influenza. The figures in parentheses are those for London itself. Two deaths from small-pox were reported, one from South Shields county borough the other from Willesden urban district. The circumstances of the latter were set out at length in our columns last week.

Notes, Comments, and Abstracts

THE PHARMACIST: HIS TRAINING AND VOCATION.*

BY JAMES F. TOCHER, D.SC., F.I.C.,
ANALYST AND LECTURER IN STATISTICS, UNIVERSITY OF ABERDEEN; PEREIRA MEDALLIST OF THE PHARMACEUTICAL SOCIETY.

I WISH in the first place to convey to the President and the Council of the Society my high appreciation of their kindness in inviting me to speak at the opening of this, the 85th session of the School. It is a great honour to me—a dug-out, a pharmaceutical fossil—to be asked to deliver the Inaugural Address, and if, because I am a fossil, or, if you like, a renegade, I expose my character too much, please be good enough to credit me, at any rate, with sincerity and conviction and with a desire to encourage those of you who are on the threshold of your career.

The Pharmacist's Training.

At this time, and in all parts of the kingdom, young men and women have gone from home to study in college, in university, and in school. The subjects are many and varied; the objects can be more readily enumerated. Is it not remarkable that without any evident systematic arrangement or plan the supply of entrants to each profession or craft or business should, generally speaking, meet the demand, and often more than the demand? Is the selection of an occupation a chance affair? Or can we explain how we find ourselves business men or professional men in our particular branch of business or profession? My statistical mind craves for such information, and its absence leads me to speculate. The son often adopts his father's occupation. The son sometimes selects the career his father opposes. The chance remark of a neighbour leads another to his place in the world. A facility or supposed facility to read Latin or to handle figures or to use one's hands may lead many into their respective niches in life. You, the students of 1926 in this school, can you assign the reason or reasons which led you to choose pharmacy as a profession? If students in general were asked to supply this information the collated data would, I suggest, be valuable to the State and be perhaps a means of deflecting many on to paths more suited to them than the paths first selected.

Human Variability.

It is obvious to us all that mankind is variable in physique, in intelligence, in character, and it is also obvious to us that these qualities are inherited. You know the story of the Aberdeen boy who, on a visit to his maiden aunt, shocked her by his wide knowledge of words, certainly not learned within the schoolroom. "My laddie," said she, "who taught you to swear like that? It's terrible." "Ye dinna learn to swear, Auntie—it's a gift," he said. A good ear, a good memory, an attentive mind, and a power of concentration are certainly inherited qualities. So far the boy was right. But he was a believer in brevity of speech. All that was wrong with him was that he had been in bad company. But although we all know that we vary in physique and in ability, do we know what proportion of the population is really able, and can we grade mankind into classes according to ability or the want of it? What a boon it would be to the teaching staff of a school or college if the students came classified according to ascertained intelligence. In the absence of such grading we have to find out the student's grade during the course of his curriculum. The pioneer work carried out by Prof. Karl Pearson at the Galton Laboratory of University College includes among its many practical results of value to the community a description of the nature of the distribution of intelligence and the numbers likely to be found in each grade of ability from a large random selected population. We learn that only a small proportion of any randomly selected population is really able. We learn other important facts, such as that ability is inherited and that the difference between one able man and another is of an average very much greater than the difference between an ordinary representative of the mass and another of his kind. We ordinary individuals have the grim satisfaction of knowing that the State legislates for us and not for the few brilliantly gifted, who can be trusted to look after themselves.

But I do not know that we can look upon the present students of the School of Pharmacy as simply a chance sample from the general population. You have come from all parts and the School of Pharmacy of the Society may attract only the abler of the young men entering the profession. Competition, struggle for existence, is the normal condition of life, the condition which provides the practical tests of ability and application. There must

* An address delivered to the students of the school of the Pharmaceutical Society of Great Britain.

eal effort and enthusiasm on the part of the student, and here must be real guidance on the part of the teaching staff. The School of Pharmacy of the Society has an able and experienced staff with an accomplished head in my friend Prof. Greenish, the genial Dean of the School. The results of the teaching must be gratifying to the Council. Students have now additional advantages accruing to them from the establishment of the Pharmacological Laboratory of which Dr. Burn is the distinguished Director. In Dr. Burn's laboratory the student will be able to study the principles underlying the biological assay of drugs, and he will get a general idea of how a posological table is constructed. What great advantages you, the students of to-day, have over former embryo pharmacists!

Standards and Methods of Teaching.

I am far from maintaining, however, that teaching is always satisfactory in this country. We must accept certain testimony that occasionally there is inefficiency or indifferent instruction. Thus we must assume that the law of distribution of intelligence holds even among professors. There are "duffers" as well as geniuses. The point of view of the student in this connection is interesting. You may have heard of the professor whose qualifications as a sportsman were undoubted, but whose efforts to impart knowledge were the despair of his class. One day while walking along a lone moorland road in the autumn, a young undergraduate noted his professorial friend in a shooting party *en route* for the hills. A sportsman of the party asked the young Scot if he knew the neighbourhood—was there anything about worth shooting. "Oh yes," was the prompt reply, "do you see that man there?" pointing to the professor; "shoot him!" We must look on teaching and examining as necessary evils. Teachers and examiners mitigate or aggravate the evils according to their character, ability, and training.

The curriculum is standardised for all, because the courses of instruction laid down by the Council of the Society embrace the minimum amount of knowledge an individual should possess before he can, as it were, be let loose on the public as a pharmacist. Incapacity must be eliminated. It is the welfare of the public and not the private interest or inclination of the individual which has to be considered by the State.

Progress of Service and Standards of Training and Examination

The minimum training and equipment of the pharmacist have gradually been raised since 1868 to meet the State's development and requirements. For what was suitable in 1868 is entirely unsuitable now. Why? Because of the great developments in the chemical and medical sciences and their application to modern needs. The origins of many diseases have been definitely ascertained, and preventive or curative remedies have followed like sunshine after a storm. If only those terrible fellows, the organic chemists, would stop putting together in all sorts of ways new combinations of carbon, nitrogen, oxygen, hydrogen, and other simple-like substances, we should get a little relief and breathe more freely. The processes are miraculous-looking, but not quite so miraculous as the sudden turning of Lot's wife into a pillar of salt by the simple action on her part of looking behind her on her last journey. You may have heard of the Aberdeenshire boy who was nothing wonderful in this sudden chemical transformation. His anxious look attracted the attention of the Sunday school teacher who had just read the biblical narrative. "What do you think of it?" she asked him. He said: "You know Eppie Maclean; she went up the village street yesterday, and she looked back three times, and then she turned into a public-house." What wonderful language we have!

What is the good, one might say, of knowing about the preparation of chemical substances with long names? Well, take two such simple instances as para-ethoxy-acetanilide and phenyl-dimethyl-isopyrazolone, which as you know under the names of phenacetin and antipyrin, are well known and frequently used by the public. The answer with regard to these two substances is that the public take phenacetin and caffeine in the same way as the more civilised of them take whisky and soda. The pharmacist must know what these substances are, how they are prepared, and whether or not they are free from contamination or adulteration. Take another instance: that of dioxy-diamino-arseno-benzol dihydrochloride. It is named in the recent Therapeutic Substances Act, and the answer with regard to this substance is that it possesses curative properties of a specific character.

ANCOATS HOSPITAL.

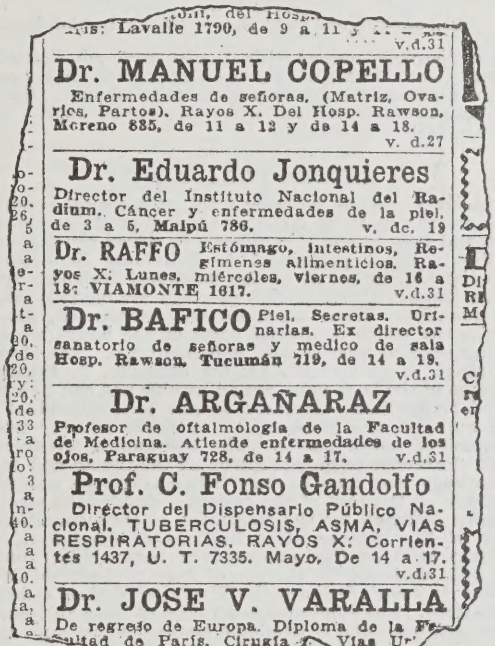
OUR attention has been called to the fact that in the Students' Number of THE LANCET, published on August 28th last, amongst the hospitals of Manchester no mention was made of the Ancoats Hospital. We are glad to note that this institution has 120 beds, with an additional 35 beds at the Convalescent Home at Great Warford, Alderley Edge. The patients treated last year were as follows: In-patients, 1380; out-patients, 8124; accident cases, 21,380. operations numbered 2402.

MEDICAL ADVERTISEMENTS IN THE PRESS.

WE have lately received a short handbook, by Mr. John Nash, called "Advertising as a Science" [1] which is written as a plea for "more accurate and scientific methods in the practice of advertising." Presumably it was sent in the hope that we would commend it as likely to be useful to members of the medical profession, but this we hardly care to do, in spite of the book's merit, for fear of appearing cynical.

Now whilst the majority of doctors in this country object strongly to anything that savours at all of personal advertisement, there are evidently many who look lightly on all cases except the most flagrant, and there is a growing body of opinion (mainly silent) which does not see why medical men should not advertise as much as they wish. Frankly competitive advertising is discouraged by the profession in most parts of the world, but within certain limits advertisement is widely practised. These limits vary in different countries. In England no one takes exception to the issue of directories giving the details of professional achievement, and it is considered permissible to allow names to appear in hospital reports and similar documents with a wide circulation.

A correspondent has sent us a cutting from an Argentine newspaper which illustrates a natural but definite extension of this principle. About one-third of a column is devoted



Dr. MANUEL COPELLO
Enfermedades de señoras. (Matriz, Ovarios, Partos). Rayos X. Del Hosp. Rawson. Moreno 835, de 11 a 12 y de 14 a 18.
v. d.27

v.d.31
Dr. JOSE V. VARALLA
De regreso de Europa. Diploma de la Facultad de París. Cirugía ... Vías Ur...

to an advertisement of a British hospital, and besides giving details about the admission of patients this contains a list of the visiting staff, with the telephone number of each. It may be argued that the publicity thus given is no more than a suitable return for the honorary services of these physicians and surgeons, and it is obviously only a concession by foreign doctors to Argentine custom. We reproduce below part of a daily column, headed Profesionales, of the *Nacion*, from which it will be clear that a plain statement of name, address, and specialty is regarded as legitimate advertising by Argentine practitioners. The list does not contain the name of any French, German, or English doctors, who are doubtless placed at a disadvantage by adhering to the customs of their own countries; but it is clear that those who thus bring their names before the public are adopting a convention by which they gain nothing over one another. If the practice were universal it would correspond to a daily publication of the local medical directory; the newspapers or magazines would be the gainers, but the multiplicity of names would largely defeat the object of individuals, for, as W. S. Gilbert remarked, "when everyone is somebody then no one's anybody."

To be really effective an advertisement must not be one of a large number exactly like it, and it is only where the use of newspapers permits a special appeal that it becomes definitely dangerous to the well-being of the profession. A list of names and degrees is defensible, where a list of

[1] London: Nash and Alexander, Ltd., Kingsway House, W.C. Pp. 85. 2*s.* 6*d.*

alleged cures is not. Qualifications and appointments may be verified as facts, but the public has no defence against the advertiser who suggests that he has special skill or qualities which his professional colleagues lack. Nor have these colleagues any redress except counter advertisement. Wholesale competitive self-praise—by all who could afford it—in the columns of our newspapers would certainly decrease the public respect for the profession, whilst the testimonials of grateful patients would be hardly less undignified and misleading. The following extract from a Chinese newspaper, whilst doubtless gratifying to the doctor concerned (who is, we understand, above suspicion of having inspired it) must be a thorn in the side of his medical competitors :—

GRATITUDE TO DR. ——.

Dr. —— —— ——, the former Doctor of the Government Civil Hospital, possesses a great stock of medical knowledge and a rich experience of surgery and healing internal diseases. He has received the degree of Medical Doctor from Hong-Kong University and is always kind and acceptable to whoever approaches him. Last year he had been engaged by the ——— Mining Administration Hospital and within a year effected a great many cures. In the last month I could not eat or drink and became so dangerously sick that many famous doctors could do no help. At last I had the good fortune to be diagnosed by Dr. —— and be healed within half a month. Therefore his benefits to me are too great and I have no other means to thank him than inserting this confession of my gratitude in newspaper thereby to introduce to the public this great efficient Doctor.

CHANG KWEI CHUN,
Chief of the Wood Store of —— Mining Administration.

Even the most ardent individualist must admit that the ingenuity and literary ability of an advertiser (or his agent) are not necessarily a function of his medical skill. How far their unrestrained exercise is for the public benefit is, of course, a matter of opinion.

ZANDER TREATMENT.

FOR many persons suffering from pathological conditions of the motor apparatus ordinary exercise produces too much strain and fatigue, and it is difficult to adjust the amount of exercise in exact proportion to individual requirements. With the aid, however, of the machines designed by Dr. Gustav Zander, of Stockholm, exercises are made a measurable quantity. These machines are constructed, some to exercise the whole or special parts of the body, others to develop selected muscles and muscle-groups. The strength and range of movement, as, for example, in flexion or extension of the knee-joint, are adjustable and can be strictly limited or gradually increased to suit each individual case or, if required, the exercise can be made entirely passive by means of motor power. The well-known physiological effects of exercise or movement on all the tissues and organs of the body can thus be fully utilised without any strain or fatigue on the part of the patient. Besides the machines specially designed for the treatment of such conditions as atony of the muscles after fracture or operation, other machines such as the motor-driven horse-riding machine have been designed for the use of busy professional or city workers to counterbalance the ill-effects of their sedentary occupations. The apparatus is installed at Bath and many of the foreign spas and is available under medical supervision at the Zander Institutes in London (6, Mandeville-place, W. 1), and Sheffield (Edgar Allen Institute). The Anglo-Hungarian Corporation, Ltd. (7, Prince's-street, Westminster, S.W. 1), is the agent for the British Empire of the manufacturers, Rossel Schwarz and Co., Wiesbaden.

A METHOD OF BOOKKEEPING FOR DOCTORS.

A SIMPLE system of bookkeeping which would enable the busy practitioner to keep such a complete record of his income and expenditure as would help him to prepare his income-tax returns without further effort would certainly be appreciated. Mr. A. P. Bertwistle has attempted to devise such a system in "The Doctor's Books" (London: John Bale, Sons and Danielsson, Ltd. Pp. 32. 1s. 6d.). The method outlined involves the maintenance of five books, three—day-book, case-book, and visiting-book—being in daily and two—cash-book and ledger—in weekly use. As the author points out, a system of bookkeeping suitable for the practitioner should be easy to understand and easy to run. We are not sure that the method elaborated by him falls into the last-named category, but probably, in time, the use of these records would become almost automatic. It would have been easier to understand if the second paragraph under the heading "Cash-book" on p. 17 had been carefully revised in proof; in the third line of this paragraph the word "cash-book" should presumably read "ledger and day-book." Mr. Bertwistle has evidently been at pains to provide a workable scheme to assist the doctor in fulfilling what is usually regarded as the most irksome of his obligations, and those who are dissatisfied with their present routine should study his suggestions.

MEASUREMENT OF ULTRA-VIOLET DOSAGE.

WE have received a brochure from Messrs. Arnold and Sons (John Bell and Croyden, Ltd.) on the measurement of ultra-violet dosage. They state that the clinical requirements are met by the use of Levy-West ultra-violet pastilles, which consist of small discs of thin card coated with a preparation on one side sensitive to ultra-violet rays, and on the other (the black side) with an adhesive which will allow the pastille to be put on the patient's skin and to adhere slightly to it. These pastilles change in tint when exposed to ultra-violet radiation and the scale of tints provided extends from 1–12 units of dose. It is stated that the pastilles respond equally well to all wave-lengths between 2300 and 3800 A.U., and that they are quite insensitive to any other wave-lengths. This is not evident from the illustration accompanying the article as the photograph is cut short at this latter wave-length—a point which bears emphasis because of the inevitable exposure to light of the pastilles during ordinary daylight use.

RELAXATION.

IN the stress of modern civilised life the ability to relax upon occasions is a valuable possession, and in a recent little book on popular health (Byways to Health. By Thomas D. Wood, A.M., M.D., and Theresa Dansdill, A.M. London and New York: Appleton and Co. 1925. Pp. 198. 5s.) a large proportion of the subject matter is devoted to relaxation. The authors quote Mr. Kipling's "Maltese Cat," the polo pony who "hung down his head and let all his muscles go slack," to get all the rest possible before the closing phase of the game. They also quote Victor Hugo, George Eliot, Napoleon and Kleinas, the Pythagorean philosopher, in the course of a couple of entertaining pages, and in this breezy way the reader is whisked through a sound book on health in a short and agreeable time. On the subject of cooking a pleasant story is told about a young reporter who wrote of a murder that "the poor woman was killed while cooking her husband's breakfast in a most shocking manner," to which was added in editorial comment "there are many women who cook their husband's breakfasts in a most shocking manner, but it is seldom that justice overtakes them so summarily."

CONTEMPORARY ENGLISH WATER-COLOURS.

MEDICAL men interested in water-colour painting—and we have reason to know that they are numerous—will find a visit to the St. George's Gallery, 32A, George-street, Hanover-square, repay them. Although there are only 70 exhibits, much of the work is by well-known painters possessing differing outlooks and practising different methods. He would be a catholic-minded person who could admire everything on the walls and a depreciator who could not find something to admire very much. The large range of the little collection proves that contemporary English water colourists are tied by no rules of any sort as to what should be tried for or how the effort should be made. In other fields than painting this is the spirit which leads to developments and secures enthusiastic followers; and so it is to-day with the most typically English branch of art.

SUSSEX PROVIDENT SCHEMES.

THE Sussex provident scheme was founded in Brighton in 1921 by the late Dr. J. F. Gordon Dill, and figures published from time to time in THE LANCET have indicated its success. In 1925 nearly £6400 was paid to the various hospitals in Brighton and district for medical services rendered to subscribers.

A scheme on similar lines to the Sussex Provident Scheme has just been launched in West Sussex under the title of the Royal West Sussex and Associated Hospitals' Contributory Fund. The new organisation has not yet been fully developed, but it is hoped that it will cover an area extending as far east as Worthing; this town may or may not be included. The general committee, it is proposed, shall comprise eight members of the board of management of the Royal West Sussex Hospital at Chichester, three representatives from the associated hospitals, two from the nursing associations, one from the doctors, and one from each group of 50 subscribers. Although at present in its very early days, the West Sussex branch of the Provident Scheme is making rapid progress; it is realised that it offers hospital treatment to subscribers as a right and not as charity.

In four years ended Dec. 31st, 1925, the Sussex Provident Scheme enabled 1843 members in Brighton to obtain free in-patient treatment for 36,681 days, and 5874 members to obtain free special out-patient treatment for 30,94 attendances; £16,164 was paid to hospitals for maintenance and treatment of members. In four years the Brighton district membership has been just over 30,000.

Harveian Oration

ON THE

DEBT OF MEDICINE TO THE EXPERIMENTAL METHOD OF HARVEY.

Delivered before the Royal College of Physicians of London on Oct. 18th

BY SIR JOHN ROSE BRADFORD, K.C.M.G., M.D., D.Sc. LOND., F.R.S.,

PRESIDENT OF THE COLLEGE AND CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

SIR HUMPHRY ROLLESTON AND FELLOWS OF THE COLLEGE,—I have, as a first duty, to tender to you, Sir, my thanks for entrusting to me the honourable office of delivering, in accordance with the wishes of Harvey, the annual oration commemorating the benefactors of this College. It is a striking tribute to the greatness of Harvey that, notwithstanding the lapse of time and notwithstanding the great benefactions received by this College from other pious founders from remote to very recent times, this oration has become more and more a tribute to the unparalleled services rendered by William Harvey not merely to this College but to mankind. This great result is, no doubt, in part dependent upon the greatness and brilliance of Harvey's discoveries as to the existence of the circulation, and the unravelling of some of the mystery surrounding the heart-beat, but it is due still more to the great conceptions he formed as to the proper methods to follow in attempting to understand the facts of Nature. It is probable that it is no exaggeration to say that the greatest and the most valuable benefaction this College has ever received, is Harvey's exhortation to the Fellows and Members of the College to search and study out the secrets of Nature by way of experiment, coupled with the example afforded by his own life's work.

Harvey, like most great men, was of so modest a character that he had little idea of the great place he himself would occupy in the history of science, and this exhortation of his, together with his desire that the Fellows of his beloved College should continue in mutual love and affection amongst themselves, was doubtless only an expression of his wishes for the successful development of this College, and thus indirectly of medicine as a whole.

THE GREATNESS OF HARVEY.

Successive Harveian orators during the last 200 years have striven to honour his memory and his services, in a series of orations dealing with different aspects of his life and work, or with the progress of scientific knowledge since his day, and the influence of this on mankind and on civilisation. Scholars have brought before us the state of medical knowledge in his time, and have also vividly portrayed the mode of his life and the conditions under which he worked. We know, thanks to their labours, what manner of man he was, and what was the influence on him of the disturbed time in which he lived. These are matters of perennial interest, and his example of philosophic calm under conditions of great national anxiety cannot fail to be an example to all for all time.

Harvey's life-work illustrates, in a remarkable manner, the many-sided character of medicine when considered as a whole, and how the men who promote its advance are often men of wide attainments in many branches of knowledge. His greatness is shown by the fact that, notwithstanding the conditions prevalent in his time, he was able to so free himself from the traditions of the past and the influence of authority and dogma, as to lay the foundations of modern science by his insistence on the fundamental importance of experiment and of accuracy of observation. Different sciences afford different opportunities for the use of experiment as a means of discovery, but the founder of the science of physiology had, in his field of study, unlimited scope for this method of advance, as prior to Harvey but little had really been effected by experiment, although it had been used by many, even in ancient times. We reverence Harvey not only for the foundation of physiology as a science and for showing how its progress is to be effected, but, as Fellows of this College of Physicians, for making plain the intimate relationship which must exist between medicine, both as a science and as an art, and physiology. Harvey combined in himself the physician and the physiologist. This, with the lapse of time and the progress of knowledge, has become increasingly difficult, and this difficulty is one common, to a greater or less extent, to all branches of knowledge, but more especially when a field of work includes a science and an art. There is some danger of a catastrophe akin to that of the Tower of Babel involving the more narrow specialists of these later days, owing to the rapid development of the new languages required to describe the results achieved in some departments of knowledge.

THE FOUNDATION OF MEDICINE ON PHYSIOLOGY.

Although the great developments of knowledge make it more and more difficult for any one individual to have anything approaching complete and detailed information even in one branch, and still more so in more than one, yet there should be, on the other hand, less difficulty in acquiring a fuller grasp of fundamental principles. After all, the magnitude of any scientific discovery is to be measured rather by its influence on the genesis of these fundamental principles, often formulated as so-called laws, than on the mere solution of the particular problem investigated. The so-called physical sciences have had in the past an advantage in this respect over the biological, in that the mathematician, the astronomer, the physicist, and the chemist have had more in common than the morphologist, the physiologist, and the pathologist. But the progress of knowledge is gradually effecting a change in this respect, and it is becoming more and more easy for the followers of the different sides of biology to meet on common ground. It is not only becoming increasingly difficult to draw a hard-and-fast line between the problems investigated by the physiologist and those of the pathologist, but even the morphologist, whether zoological or botanical, is now pursuing with zeal purely physiological methods in order to further his science, even on its morphological side. Harvey, as a physiologist, would have rejoiced at these developments if he had known that the colour of an animal, and even its form and mass, to say nothing of its sex, were under the influence of, and capable of being modified by, the functional activity of certain glands.

Harvey was, as just stated, a physiologist and a physician who practised his profession, and was daily face to face with urgent and distressing problems, as we all are. We all agree that our improved methods of coping with these problems are ultimately dependent upon his great discovery; and it is a trite observation that medicine must be founded on physiology, and that the study of healthy processes must precede that of morbid ones.

Observation and Experiment.

But the debt of the art of medicine to the science of physiology is greater than this, and the value of physiology to medicine is not to be measured merely by the direct practical utility, great as it may be and has been, of individual physiological discoveries, even when these are, like Harvey's, of a truly epoch-making character. The art of medicine must of necessity be reared as a superstructure on the science of medicine unless it is to be indistinguishable from mere empiricism; and the science of medicine, like other sciences, can only be advanced by observation and by experiment. When we reflect on what has

been done in the past by the observation of our predecessors, from the most remote to recent times, we cannot fail to record our admiration of the great intellectual qualities that these observers must have possessed to have enabled them to achieve the results obtained. The knowledge of the natural history of disease is a subject of vast importance to the art of medicine, and one that can only be acquired by observation. Nevertheless, as the late Lord Moulton has well said, when we are reduced to observation science crawls. If we are to treat a disease successfully we must know a great deal more about it than its natural history—i.e., its course when it is allowed to pursue its career unchecked. Experiment as a method of furthering the progress of any given science is capable of achieving great results, and—again to quote Lord Moulton—"As soon as you can bring experiment to bear upon a subject you are free, but as long as you can merely observe, your progress is slow. The reason is that experiment is like cross-examination: you can put the question you want, and Nature always answers it."

Experiment, however, is not equally applicable to all sciences, and from the circumstances it is obvious that in medicine its scope must necessarily be limited. This is, doubtless, one of the reasons why the progress of the science of medicine has been slower than we could wish, but another is to be found in the profound complexity of the problems that have to be solved. This complexity is not only obvious in the consideration of broad general questions, such as the nature and causes of disease, or of individual diseases, but applies often to our daily work of the mere recognition of the nature of the malady in an individual patient. We are often baffled by the complexity of this, and nothing is more common in the experience of practitioners of our art than to find suddenly that what seems simple and obvious is by no means so. The complexity of the problems daily before us is apt to react on the mind of the physician and produce, even in this rather materialistic age, a tendency to regard the phenomena of life, and especially of disease, in an individual, as scarcely subject to the same rigid laws of cause and effect that we all recognise as binding in the physical world. If this belief, even in a modified and attenuated form, is once entertained, it causes a looseness of thought that is most inimical to the real progress of knowledge in medicine; and it is here that the study of physiology and the work of Harvey have rendered the greatest service to medicine. Harvey, by experimental work, by clear thinking, and by accurate observation, laid the foundations of physiology as a science, and those who have followed in his path have continually added to his foundations, so that now no one questions its right to rank as a science, and no one disputes the fundamental proposition that in physiology, as in physics, like causes produce like results. If the excitation of the vagus nerve causes stoppage of the beat of the heart in one case, and acceleration in another, or possibly in the same animal at another time, it is not, as Majendie thought, due to the variability of vital phenomena as such, but is due, as Bernard, the great exponent of "determinisme," taught, to the conditions not being really the same. It is perhaps superfluous to mention such an attitude of mind as regards physiology, but perhaps, even now, we are not altogether free from such a way of looking at things in human medicine, and Majendie's way of thinking has, perhaps, some followers. It is, of course, much more simple to render the conditions the same in physiological observations than in medicine, although even in physiology it is often difficult, as the discordant results of many competent observers show. In human medicine the difficulties are infinitely greater, and hence we should regard the results already achieved as a most remarkable monument to the acumen of clinicians, who must, in order to have obtained the results we are familiar with, have been possessed of exceptionally sound scientific methods of observation.

The Conditions of Progress.

The history of the progress of our knowledge of medicine affords countless instances of the extreme accuracy of observation possessed by the foremost clinicians of the day, but although their observations were often excellent and their descriptions leave little to be added to, their explanations of the observed facts were not of the same value. Variations observed in the course of maladies were often explained in an artificial and non-scientific manner, owing to the want of appreciation of this law that like causes produce like results, and that if the results are different in apparently similar cases, the real explanation is not some variability on the part of Nature, but that in reality, although the cases seem similar, there is some hitherto undiscovered difference. One type of thinking closes the door to further work and real progress; the other is one of the most fertile causes of discovery. Shrewd clinicians observed, long ago, that some cases of typhoid fever lasted four weeks, others were said to abort in two weeks; hence it was inevitable that a certain vagueness and uncertainty of belief should be entertained with regard to the action of the virus of this disease; and it is difficult not to think that such beliefs react on the mind and influence profoundly our outlook on problems that beset us, and on our methods of coping with them. The progress of inquiry shows that the differences in the duration of the febrile period of typhoid fever are, at any rate sometimes, due to the differences in the organisms causing the disease, and we now talk of the enteric group, including both typhoid and paratyphoid bacilli. It is quite true that this increase of knowledge does not settle the problem, as there still remains the question of the relation and origin of the paratyphoid group of organisms; but this progress of knowledge has had the effect of demonstrating that the duration of so-called typhoid fever is not a matter, so to speak, of chance, but depends—or may depend—on the specific nature of the organism causing the illness. The fact that one organism causes an illness of four weeks' duration, and another, quite distinct but allied one, causes an illness of two weeks' duration, is a very different matter, from the point of view of scientific medicine, than the statement that the illness of typhoid fever may last either four weeks or two weeks. The attitude of mind caused by one belief is calculated to cause a certain bewilderment of feeling and one both of hopelessness and helplessness of arriving at any definite attainment; the other encourages the inquirer that long-continued patient work may reveal, at any rate in part, the mystery, and show that the phenomena of disease, complex as they are, are nevertheless amenable to the same laws and conditions as those governing the biological and physical worlds. Further, the apparent variability of disease becomes, instead of an impediment, a spur to further inquiry, and a stimulus to research, and such inquiries are often rewarded by discoveries that add a definiteness to our knowledge that is of the greatest possible value. It would not have been possible for this attitude of mind to be developed in relation to the problems of medicine unless the study of physiology and of vital processes generally had been placed on the surest foundations by Harvey by the use of the experimental method, as it is this method, in its many developments, that has enabled us to see that in living things like causes produce like results, and that the exceptions are apparent only, not real.

The Debt of Medicine to Experimental Physiology.

Further, in the past there has been much theorising, both in physiology and in medicine, often on very insufficient data. The experimental method has afforded a very certain and conclusive test of the inaccuracy of much work of this nature, and such results, important as they are, are, nevertheless, of a negative character, and have sometimes led to the belief that there is some antagonism between experimental inquiry on the one hand and the result of

observational methods on the other. Doubtless much loose thinking and many erroneous deductions may occur as the result of the direct and immediate transference of experimental animal results to the explanation of the phenomena of human disease, but this, again, arises from neglect of the fundamental principle that the conditions in the two cases are not alike, and also that we constantly think the phenomena of disease to be much simpler than they really are, and are perpetually hankering after cut-and-dried explanations of what are, in reality, exceedingly complex phenomena. Far be it from me to minimise the direct and immediate gains to medical knowledge and to medical practice that have resulted from individual discoveries in experimental physiology, as, for example, the notable discoveries as to the functions of the thyroid and its secretion, and many others. Harveian orators have dealt with these in such an able fashion that it is superfluous to dwell on them, and I would urge to-day that perhaps of even greater importance is what I may call the general effect on medicine of the development of physiology as an exact science, and the influence that this will have, in the course of time, in making the science of medicine as exact and as worthy to be deemed a science as any other branch of natural knowledge. Clinical observation, when carried out by a great mind and in strict accordance with scientific method, has achieved most striking results, results which are entitled to our highest admiration when, as already stated, we consider the extreme difficulty of the problems and the scanty means at our command to solve them. Often, however, the results, great as they are and accurate as they are, lack the precision of detail that sometimes the experimental method is capable of supplying, and then the experimental method is responsible for the completion of that which has been truly founded by clinical observation.

Hughlings Jackson and Cerebral Localisation.

A striking illustration of this is afforded by the history of the discovery of what is known, shortly, as localisation of function in the cerebral cortex. Here the fundamental work was done by that great clinician and profound thinker, Hughlings Jackson; and when we reflect that by the study of a very limited number of cases of hemiplegia and of a series of cases of fits, and by the careful correlation of the phenomena observed during life with the lesions found after death, he was able to arrive at the conclusion that voluntary movements were represented in a certain area of the cortex, we have a magnificent example of the accurate and far-reaching deductions that may be drawn by a master-mind. Nevertheless, even in such a case as this, the subsequent experimental work was able to give a precision and supply a mass of detail that greatly enhanced the original fundamental discovery. So much is this the case that many came to think that cerebral localisation had been discovered solely by the experimental method, whereas the fundamental facts were really the outcome of clinical observation.

The greatness of Jackson's conceptions is well seen in the fact that he recognised that cortical localisation was concerned with the representation of movements and not of muscles, and, indeed, with a special kind of movement—namely, voluntary movement. In the earlier days of experimental work on this subject some confusion was introduced by certain observers falling into the error of looking for so-called centres for the representation of muscles, and it was only later that inhibition of antagonistic muscles, as well as contraction of other muscles, was also recognised as a matter of cortical representation. Anyone who has actually seen the movements called forth by the electrical excitation of the cerebral cortex will experience quite different mental impressions from those he will have felt by watching an epileptiform seizure, perhaps confirmed subsequently by seeing the position and nature of the lesion responsible for it. In the one case there is a definiteness and certainty that in the other is apt to be replaced, at the best, by a feeling of high probability. And yet, if we are to succeed in our endeavours to cope with the facts of Nature, we must aim at possessing certain and not probable knowledge. It may be that this is often, in our work at present, unattainable, but it is the great thing to aim for in all our work. Perhaps some of our mistakes in the practice of our art arise from not clearly differentiating between what we really know and what is only probable; and sometimes, perhaps, we speak with an apparent certainty about matters that are not, in our present state of knowledge, really as certain as we would like them to be. The touchstone of the experimental method of Harvey is a useful corrective whenever and wherever it may be applied to questions of this nature. The modern physiology of the central nervous system, investigated by the experimental method, affords a striking example of the extraordinary precision of knowledge that may be obtained by the use of this method, and, thanks to it, a flood of light has been thrown on the complex problems of the mechanisms involved in posture, equilibration, coördination of movement, and perhaps on the still more complex mechanisms associated with the highest functions of the brain. Nevertheless, in an oration associated with the name of Harvey it may perhaps be possible to illustrate the principles of the profound influence exerted by experimental physiology on medicine by seeking an example in that branch of physiology so closely associated with Harvey—namely, the beat of the heart.

The Experimental Method of Harvey applied to the Heart-beat.

I am not so much concerned to-day with giving a record of individually important discoveries that have been made from time to time whereby our knowledge has been increased and our power of recognising, and treating with some success, individual diseases, has been extended; but, rather, with the nature of the conceptions we form of the phenomena of heart disease as we see them clinically in the light of the exact modern physiology of the heart, as revealed by the use of the experimental method of Harvey.

The beat of the heart, from the earliest times to the present, has been looked upon as emblematic of life by poets, philosophers, and thinkers, and has always had an element of mystery and awe attached to it. No physician will deny that in disease there is much of apparent mystery in what may be called the natural history, or, if you will, the clinical course, of heart disease; further, that the clinical picture presented by individual cases, even where relatively simple lesions are present, is one with much individual variety, that the phenomena are complex and difficult to analyse, and hence there has been much uncertainty of opinion, both in diagnosis and in treatment. Such differences of opinion existed not only with reference to questions of interpretation or explanation, but even in reference to what we should now regard as mere questions of fact. There must be some present here to-day who will remember a controversy as to the actual time of occurrence of certain well-known murmurs associated with a common valvular disease. When the methods available for clinical observation led to such remarkable differences of opinion amongst physicians of recognised skill and ability, it is not strange that many keen and able minds should have felt that the problems of medicine were so difficult and so complex that it was beyond their power to really solve them with the means at their disposal; and this attitude of mind is one very inimical to the progress of our science and our art. The method of Harvey of seeking the secrets of Nature by way of experiment shed a flood of light on the problems that had baffled those who confined their methods to observation. Not only was this the case, but what is of supreme importance to recognise is the fact that many of the men who in recent times remodelled our conception of the nature of cardiac disease by the fundamental character of their discoveries of the

nature of the cardiac beat, were men who devoted their lives to the investigation of the facts of Nature with no other object in view than that of adding to knowledge for its own sake. Great as their discoveries were, they had no idea of their practical bearing on heart disease, and some of them, indeed, were men who had no knowledge of heart disease as such, and never undertook their work with any idea of adding to our knowledge of heart disease. Further, the discoveries of the pure clinicians, remarkable as they were for the acuteness of their observation, were largely dependent on making use of the methods and apparatus of the laboratory in the investigation of clinical problems. The polygraph and the electrocardiogram gave certain and accurate information where previously other methods of observation had led only to the dissemination of views, explanations, and theories of varying degrees of probability. It is one thing to be able to actually demonstrate beyond cavil that the auricle of the human heart in a living patient is in the state known to us as that of fibrillation, and another to talk of lack or failure of compensation, with no clear mental picture of the meaning of the words used. Anyone who has seen a fibrillating auricle in the living animal in the laboratory has a mental picture that is not easily forgotten, a picture of a singularly concrete and definite character, with an element of reality about it that cannot fail to be a useful reminder to him when he stands at the bedside of a patient suffering from the effects of this condition. It is, of course, quite true that the acute clinical observers of the past had recognised the clinical picture produced by this condition, and had described quite accurately some of its manifestations. We can but admire their acumen, but they were necessarily unable, owing to the lack of physiological knowledge and the want of adequate methods, to determine the true cause of the symptoms, and to correlate the lesion with its results. Hence the inevitable temptation, to some minds, to speculate and theorise vaguely instead of confining themselves to mere observation, and hence the further elaboration of more and more speculation and ultimately much confusion as to what was speculation and what was firmly established by observation. This has often been most harmful to the real progress of medicine, owing to the development of loose methods of reasoning, and the frequent impossibility of bringing the matter in dispute to a decision by the crucial method of experiment.

The Experimental Study of Auricular Fibrillation.

The history of the development of our knowledge of fibrillation is singularly interesting as affording a striking example of the experimental method having substituted a clear, definite, and easily proved condition for what was previously a most vague, indefinite, and even intangible conception. But the history of the discovery of fibrillation is even more interesting and important from another point of view, and teaches a lesson of supreme importance to those who are always insistent on investigation being directed to some immediate practical aim. Fibrillation was discovered by a physiologist who was attempting to ascertain where the beat of the heart had its origin—in other words, whether the heart contained a so-called centre from which the beat arose. In the course of his inquiries he found that on stabbing the heart with a fine needle a condition of what we now call "fibrillation" ensued. Sometimes this followed a single puncture, sometimes many were required. Later it was found that faradisation of the exposed heart with a current of moderate intensity produced the same result. Sometimes the condition of fibrillation was transitory, in other cases it was permanent; the heart did not recover, and death ensued.

It is unnecessary to-day to go into all the details of the many subsequent investigations on this interesting subject; all that it is necessary to point out here to-day is that this condition of fibrillation was a discovery of experiment produced by such crude and simple methods as repeatedly stabbing or faradising the exposed heart. I can well remember that it was a common method, some 40 years ago, to kill an animal at the end of a physiological experiment by faradising its heart, and so producing heart delirium or fibrillation. No one who saw fibrillation would have suspected that it was a common condition in human heart disease, and that almost every hospital ward had cases suffering from it, either temporarily or even for long periods of time. It might, indeed, have been argued very plausibly that it was inconceivable that such crude experiments could have any possible use or bearing on vital processes, and still less on human heart disease; and yet we see that the exact opposite is the case, and that, crude as the experiment was and remote as was the connexion between the normal dog's heart and human mitral stenosis, and although the mind of the investigator had no thought of heart disease in his inquiry, nevertheless this crude and apparently idle experiment was of the utmost significance for the intelligent understanding of one of the commonest forms of heart disease.

THE RECIPROCAL RELATIONS OF PHYSIOLOGY AND PATHOLOGY.

Another lesson may also be learned from consideration of these results, and that is the reciprocal influence of physiology on pathology, and of pathology on physiology, and how extremely artificial the boundary is between these two departments of knowledge, and how, if we are to have an adequate conception of even relatively simple vital processes, it is necessary to study them with the broadest possible outlook. A pure and rigid physiologist, studying only the normal activity of the heart, would scarcely be prepared to admit that the circulation, in a highly organised mammal, could be maintained when the rhythmical activity of the heart was so disorganised that auricular fibrillation was present. Nevertheless, clinical medicine proves that, even in man, such is the case. Surely such facts as these are of the utmost value, not only in our immediate daily work and in our attempts to treat disease and relieve suffering, but still more so in our appreciation of the nature, the complexity and, more especially, the adaptability of the activities of living matter. Marvellous as are the various methods by which a circulation sufficient for the needs of the normal animal is effected—and this is well shown by the study of comparative anatomy and comparative physiology—the marvels of the relative efficiency of the disordered circulations of heart disease are not any less. Certainly the study of these conditions not only widens our conceptions, but is also a useful incentive to our therapeutic efforts when a more limited and narrow belief might lead us to be less hopeful as to the possibility of procuring relief or cure in these conditions.

The Work of Gaskell and Romanes.

The history of the study of the phenomena of fibrillation has been cited as an illustration of the very close relationship that exists between experimental science and the daily work of the physician, especially if we wish to found our art on a secure basis of science and if we desire to eschew empiricism where this is possible. The same illustration may be found equally well in the history of the development of our knowledge as to the nature of the normal beat of the heart and of its disordered action in disease. Here also we see the extraordinarily close connexion between pure physiology on the one hand and the interpretation of the clinical symptoms of heart disease on the other. It may seem at first strange to assert that our present conceptions of the fundamental facts in the pathology of heart disease owe their origin to researches conducted by a physiologist on the nature of the muscular contractions in the umbrella of the jelly-fish, but it is really an unexaggerated and plain statement of fact. Romanes, in the 'seventies, carried out a series of very beautiful but very simple experiments on the nature of the

rhythmical contractions of the umbrella of jelly-fish, being especially interested in the question whether the wave of contraction was transmitted via the nerve plexus—that intermingles with the sheet of muscle in these organisms—or whether it was of purely muscular origin. He had but little apparatus beyond a pair of scissors, and, for some purposes, a simple recording lever and a smoked surface. Romanes, in the course of his work, discovered the fundamental fact that what is known as a block was a phenomenon dependent purely upon muscular changes, and due sometimes to a mere narrowing by section of the width of the muscular bridge connecting the two portions of a contracting muscular sheet. In other words, a block might be produced by local alterations in the conducting properties of the muscle itself. Further, he showed that delay in conduction could also be effected by such alterations in the muscular bridge produced by narrowing of the connexion, and that delay in transmission of a muscular wave from one part to another was not in itself any evidence of the intervention of the nervous elements. The importance to us, as physicians, of Romanes's work was that it was the origin of the slightly later and epoch-making work of Gaskell on the nature of cardiac action. We owe to Gaskell a very large part of our modern conceptions of the physiology and pathology of the heart muscle, and Gaskell's work, like that of Romanes, is beautiful in the extreme simplicity of the bulk of his experimental work. He developed and amplified in the heart of fishes, of amphibia, and of reptiles, and especially in the heart of the tortoise, the fundamental experiments of Romanes; and, like Romanes, some of his most striking results were obtained by the use of experiment, with little more apparatus than a pair of sharp scissors. His fundamental experiment of producing a block by section of the muscle of the auricle, so as to leave only a narrow bridge connecting the sinus portion of the auricle with the ventricular portion, was performed on the heart of a skate on the deck of a yacht whilst cruising off the west coast of Scotland, not far from where Romanes worked in his seaside laboratory on his jelly-fish.

Gaskell was the protagonist of the doctrine of looking upon the heart as a muscle and of unravelling the properties of cardiac muscle, and of correlating them with those of other muscular tissues, voluntary and involuntary. Further, he correlated structure and function, as shown by the different physiological properties of auricular and ventricular muscle associated with their different structure, and he emphasised, as also did Roy, the great part played by the auricle in the physiology of the heart-beat and its intimate association with the nervous system.

Another of Gaskell's great conceptions was that of the independent rhythm of the separate cavities of the heart and the way in which, under certain abnormal conditions, the prepotency of the sinus end of the heart might be interfered with, and an independent rhythm initiated in some other portion of the heart, as, for example, the ventricles. We owe to him the conception of the heart as consisting of a number of muscular cavities each with an independent rhythm, but the whole dominated by a prepotency at the sinus end. Nevertheless, under certain conditions this might be disturbed by the manifestation of the independent rhythm of some other portion of the heart, more especially the ventricle.

Gaskell's work on the nervous system was of such a striking character, and led to such far-reaching conclusions, that sometimes we are apt to forget that his earlier work on cardiac muscle was certainly of equal importance, and has had a very great influence on the progress of modern pathological knowledge, especially by clarifying our ideas as to the nature and mode of origin of the cardiac rhythm. We also owe to him and to Roy the conception that the main function of the auricle is to act as a regulator of cardiac activity. As has already been pointed out, all these fundamental facts were discovered by experiment, with very simple apparatus. But in another branch of physiology to which medicine is also greatly indebted the experimental methods necessary in order to elucidate the phenomena were of a more complex character. Forty years ago electrophysiology was looked upon by many as a recondite branch of investigation which might perhaps be of interest, but which could not possibly be of any practical use. Physiologists, like Burdon Sanderson, were engaged in the investigation of the electrical phenomena associated with the activity of vital processes, simply and solely because it was the most delicate physical method available for the investigation of such phenomena. It is a striking comment on such views as these to reflect that the study of the electrocardiogram in the human subject and in animals was the actual means by which the condition of fibrillation was verified to exist in the human subject. Furthermore, the electrocardiogram gives us the most definite and accurate knowledge of the real state of the cardiac muscle, as shown by the nature of its activity.

The Electrocardiograph.

One of the most striking everyday illustrations of this may perhaps be quoted. Every practitioner is aware that in mitral stenosis under some conditions the presystolic murmur is absent and in others it is present. I know of no more striking demonstration than to be able to show, by means of the electrocardiogram, that in the one case the auricle is contracting rhythmically and in the other it is not. The electrocardiogram removes all doubts and difficulties as to the interpretation of this phenomenon, and gives an element of certainty that is not obtainable by any other method. It has thus led to a precision in the interpretation of some clinical phenomena that leaves little to be desired. On the other hand, it requires an elaborate installation and a considerable amount of technical and special knowledge, and thus is ill-adapted for ordinary routine observation.

Although we owe to the electrocardiogram the complete demonstration of the existence of fibrillation in the human heart, we can recognise the presence of fibrillation by other and simpler methods. It is a common thing in the history of science that the interpretation of facts may require difficult and elaborate experimentation, whilst their recognition can be effected by the use of simpler methods. The electrocardiogram may be useful for both purposes, but it is perhaps more especially valuable as an instrument of research when attempts are being made to ascertain the fundamental causes of certain clinical phenomena.

The Work of Ringer.

Another striking illustration of the profound influence of a simple experimental method of inquiry in advancing our knowledge of the nature of the heart-beat, and indirectly of all vital activities, is afforded by Ringer's work on the effect of minute quantities of calcium, potassium, &c., on the heart. His discovery that the activity of a living tissue was dependent upon the presence of calcium was a great discovery, and one the full effects of which are only now beginning to be realised. He, further, had the very remarkable foresight to anticipate in some respects the modern doctrine of ions. Ringer's work is perhaps especially noteworthy inasmuch as it was the work of a man trained as a clinical physician, who did not embark on experimental inquiries until he had reached middle life, and then devoted himself to the investigation of what might be regarded as abstract problems of pure physiology. These observations, like those of Gaskell, were what may be called fundamental, inasmuch as they altered our conceptions of the nature of vital processes, in that they replaced what was vague and indefinite by concrete physical and chemical facts. These observers certainly fulfilled Harvey's exhortation to the letter, by

searching and studying out the secrets of Nature by way of experiment.

I have attempted, in this oration, to show that the pursuit of knowledge by Harvey's experimental method is not to be regarded only as a means for the acquisition of results of great value in our daily work, but also that it is of supreme importance in laying the foundations of our conceptions as to the nature of the processes we see at work in disease, and that, thanks largely to it, we may claim that medicine has a scientific status as a branch of natural knowledge.

Hence in medicine, as in biology generally, it is true that like causes produce like results, and the successful investigator must realise the profound truth of the lines :—

> And Nature the old nurse took
> The child upon her knee.
> Saying, ' Here is a story book
> Thy Father has written for thee.
>
> Come wander with me,' she said,
> ' Into regions yet untrod,
> And read what is still unread
> In the manuscripts of God.'
>
> And whenever the way seemed long,
> Or his heart began to fail,
> She would sing a more wonderful song,
> Or tell a more marvellous tale.

An Address

ON

WORKMAN'S COMPENSATION AND THE SURGEON.

Presidential Address delivered at the Section of Surgery, Royal Society of Medicine on Oct. 20th, 1926,

BY V. WARREN LOW, C.B., M.D. LOND., F.R.C.S. ENG.,

SENIOR SURGEON TO ST. MARY'S HOSPITAL, LONDON; CONSULTING SURGEON TO THE LONDON, MIDLAND, AND SCOTTISH RAILWAY.

As far back as 1846, the year in which Lord Campbell's Fatal Accidents Act was passed (which gives the right of action for compensation to the families of persons who are killed by the negligence of others), a Select Committee on Railway Labourers, shocked by the casualties among the 200,000 navvies engaged in the work of railway construction, reported in favour of making railway companies pay compensation for accidents. The words were :—

" By making the companies liable instead, your Committee contemplates fixing that part with the liability who has the greatest power to prevent the injury and the greatest means to repair it."

That was in 1846, and it was not until 1880, and then only tentatively, that steps were taken by our legislators to give effect to this very salutary suggestion.

I have heard it suggested, even in the precincts of St. Stephens, that surgeons are apt to err on the side of caution and reaction, particularly with regard to certain manipulative methods, but I think I can claim that the surgical world moves more rapidly than this.

In 1880 was passed the Employers Liability Act. Before this date the only legal remedy open to the workman who had suffered bodily injury, when following his employment, was a common law action against his employer. Such an action is only available when it can be shown that the personal injury complained of arose from the employer's personal negligence, or because he knowingly employed an incompetent servant. Even then the plaintiff may have to meet the defence of *volenti non fit injuria*, a doctrine which deprives a servant of the right to recover damages for personal injury, if, appreciating the risk he is running, he agrees expressly or by implication to accept that risk. Furthermore, a counter charge of " contributory negligence "—i.e., want of ordinary care on his own part—may, if substantiated, deprive a workman of success in the action.

Even if the plaintiff successfully overcomes these two methods of defence there remains the even more serious obstacle of the doctrine of " common employment," which excludes liability when the injury is caused to the workman by reason of the negligence of a fellow workman in the employment of the same master. That the injured workman was bound to obey the orders of the fellow servant, whose negligence caused the injury, makes no difference.

The Employers Liability Act imposed on the master liability for accidents, causing injury or death, brought about by defects in works, plant, or machinery, due to the master's negligence, and for similar accidents caused by the negligence of fellow servants entrusted by the employers with duties of superintendence. The Act did not deprive the employer of the defences of *volenti non fit injuria* or contributory negligence. It was also legal for the workman to contract out of the Act.

The Workmen's Compensation Act of 1897 introduced into English law an entirely new principle. It initiated the idea that a workman injured in his employment should be entitled to compensation, irrespective of any question of negligence. This new principle thus introduced was stated as follows in the first section of the 1897 Act :—

" If, in any employment to which this Act applies, personal injury by accident arising out of and in the course of the employment is caused to a workman his employers shall . . . be liable to pay compensation."

Only certain employments were mentioned, and these were in connexion with what would be described as the more dangerous trades. In 1900 the Workmen's Compensation Act was extended to agriculture, and thus imposed upon a class of small employers—viz., the small farmers—the liability to pay compensation. The two principles of the 1897 Act that it should apply only to the more dangerous trades and, generally speaking, impose liability only upon the larger employers, were thus departed from. The Workmen's Compensation Act of 1906 codified and extended the Acts of 1897 and 1900. The 1906 Act extended to all employments with some few specified exceptions and industrial diseases were brought within its scope. The innovation which was perhaps of the greatest interest to our profession was that the county court judge was enabled to summon a medical referee to sit with him as assessor, and it was also made possible for the parties to refer their dispute, as to the extent or cause of the workman's incapacity, to a medical referee. In 1919 a Departmental Committee was appointed to inquire into the working of the present system of compensation to workmen for injuries sustained in the course of employment. This Committee reported in 1920.

It is to this report that I am indebted for my information as to the history of the previous Acts and from which I quote freely. As a result of this report the Act of 1923 was passed. In this additions were made to the weekly compensation payable under the Act. Compensation was made payable on the fourth day of incapacity (the first three days being paid for if the incapacity lasted for four weeks) instead of, as under the old Act, in which compensation was paid only at the end of the first week (this week being paid for if the incapacity lasted a fortnight). The 1923 Act also raised the maximum income for non-manual workers, included in the Act, from £250 to £350 per annum. There were also other alterations in procedure which are not, however, of much interest to us. Finally, in December, 1925, an Act was passed to consolidate the law relating to workmen's compensation. In a large measure this repeals the 1923 Act and entirely repeals the 1906 Act.

The Act of 1925 is practically on the lines of that of 1923, but generally simplifies the procedure. What perhaps is of most interest to us is that an employer can diminish or end the weekly payment to a workman if the certifying medical practitioner gives

a certificate that the workman has wholly or partially recovered, and if after the lapse of a certain specified time no counter certificate by another medical practitioner has been furnished by the workman. In the latter case the parties may go before the medical referee who can decide the case. This power was present in the former Acts, but not so clearly expressed.

THE OBJECTS OF LEGISLATION.

To its earliest advocates employer's liability was rather a means of securing greater protection for the workman's life and limb than of providing compensation for those injured by industrial accidents. The idea was that if accidents could be made costly to the employer he would thereby be induced to take steps to avoid them. Whatever may have been the original intention the plan by which accidents were to be prevented by being made costly was defeated, at any rate for the time being, by the growth of accident insurance. The effect of this was that the liability imposed on the individual employer was no longer seriously felt and the provision of some measure of support for the workman and his dependants was looked upon as the sole proper function of the Employers Liability Act. There are, as you know, the Factory and Workshops Acts and the various Mines Regulations Acts which are intended to provide for the prevention of accidents.

There is, however, no reason why the Workmen's Compensation Act should not also contribute towards improving the measures taken for the prevention of accidents. In America, although Workmen's Compensation legislation was unknown before 1906, considerable advance has been made in this direction, and apparently originated with the insurance companies. "Merit rating" is the means by which workmen's compensation statutes have been made to advance the accident prevention movement in America. It involves recognition of the principle that the employer who takes all reasonable steps to safeguard his employees should pay less for accident insurance than the employer who fails to take such steps. This is assisted by an organised system of inspection, and, in the case of mines, by a safety engineering service, which devotes itself to the improvement of the safety conditions of each mine.

It is interesting to note that very much the same influences are now in America endeavouring to speed up the complete recovery of the injured workman and to lessen the time during which he draws compensation allowance. In 1920, according to the report of the Departmental Committee, the only approach to anything of this kind in this country is that by their system of "special rating" insurance companies, in respect of large risks paying, say, £10,000 a year in wages, reduce rates where the experience of two or three years shows "few accidents, as a result of good management, good plant, and all that." Reduction of premium follows experience alone. There is no systematic inspection; the existence of a safety or welfare committee is not a factor, and no reduction of premium is offered on the ground that safety precautions are taken. It is obviously to the interest of those employers, who are large enough to insure themselves, that the incidence of accidents should be as low as possible, but whether their system of accounts would show whether or not they would merit the reduced rate for "few accidents" were they insured outside I do not know.

That the matter is of some importance to us all can be gathered from the figures given by the departmental report in 1920. The present system, it says, imposes on employers a burden of upwards of £8,000,000 per annum, and the total number of workers within the Act is calculated to be about 15,000,000.

WHAT IS AN ACCIDENT?

To uphold a claim under the Act for personal injury it is necessary to show that the injury was sustained as a result of (1) an accident arising out of and in the course of the employment, or (2) one of the industrial diseases brought specially within the scope of the Act.

The meaning of the term "accident" is now well settled by judicial interpretation. In the earlier cases the Court of Appeal held that the idea of something "fortuitous and unexpected" was involved in the term "accident." The House of Lords, however, have applied a construction which is more favourable to the workman. In the words of Lord McNaghten, "the expression 'accident' is used in the popular and ordinary sense of the word as denoting an unlooked-for mishap or an untoward event which is not expected or designed." At a later period this definition was extended, and it was decided that the mishap or occurrence must be looked at from the workman's standpoint, and that whatever its cause or origin it will be treated as accidental unless designed by the workman himself. This definition has been held to be wide enough to include such cases as heat-stroke, chill developing into inflammation of the kidneys, and the rupture of an advanced intrathoracic aneurysm.

While an "accident" must be due to some particular occurrence at some particular time this condition does not necessarily exclude disease. For example, a workman who had been sorting infected wool contracted anthrax in the eye. "It was found," states the report, "that at a particular time a bacillus from the infected wool had alighted on his eye." (To the legal mind, I believe a bacillus is something like a gnat.) A Lord Chancellor observed—

> "that while it was essential that there should be some particular occurrence happening at some particular time . . . what that particular time was is immaterial so long as it reasonably appears that it was in the course of the employment."

Diseases of gradual onset such as lead poisoning are on a different footing. These cases are not "accidents," because they are not traceable to any particular occurrence in the course of employment.

The workings of the legal mind on medical matters are to me always a mine of interest. One would have thought that the mind which could have envisaged a bacillus alighting on the eye would have made little difficulty of the inclusion of a particle of lead in a nerve-cell. Fortunately both these conditions—anthrax and lead poisoning—are scheduled under industrial diseases, and there is no necessity to invoke the term "accident."

THE BASES OF A CLAIM FOR COMPENSATION.

To succeed in a claim for compensation it must be established that the workman not only suffered "personal injury by accident," but also that it was an accident arising "out of and in the course of his employment." These words were the foundation of the 1897 Act, and have been reproduced unaltered in every Act since. The matter was thoroughly discussed in the Departmental Committee, and it was finally decided that it was desirable that the phrase, which had been the subject of so much judicial consideration, that its meaning was well settled, should be retained in that same form. The view was expressed that—

> "as there must be some limiting words, and as these words have received judicial construction over and over again, it would be wiser that they should be retained rather than that any fresh form of words should be substituted."

It was also pointed out that other States, which have in recent years adopted workmen's compensation legislation, have imported the classic British phrase. In the United States, for instance, only four States use alone the phrase "in the course of the employment," while in all the others an accident must arise "out of" as well as "in the course of the employment." In France the expression is "Les accidents survenus par le fait du travail ou à l'occasion du travail."

I think it may be stated as a fact that, owing now to the number of cases that have been decided under those Acts, and to the manner in which the law has been codified and rendered more simple, the legal position of any plaintiff, except in very rare cases, is clear provided the facts can be proved.

With very few exceptions the facts in dispute are in connexion only with the medical aspects of the case, and it is here that the whole matter bristles with difficulty and is often befogged by doubt. It must also be remembered that there is no court of appeal on the facts of the case. Appeal is, I understand, allowed only on points of law, and not on the much more controversial matters involved in the medical evidence. To the legal mind, untrained in medicine, it must sometimes appear that the opposing doctors, apparently in all good faith, are expressing views on the same circumstances which are poles apart. Often the difference is more apparent than real, and depends more on different methods of expression or on inequalities of emphasis than on any real divergence of opinion on what are the essentials of the case.

But quite apart from this there is, in this class of case, plenty of room for an honest difference of opinion with regard to the essential points at issue. This difficulty is not lessened when the plaintiff, either from ignorance or from motives less naïve, exaggerates or imagines the symptoms which are responsible for his incapacity. Yet it is on controversial material like this that a tribunal, untrained in medicine, may have to come to a decision. I am referring to those cases where a county court judge sits without a medical referee. From this decision on the medical evidence there is no appeal, as the courts above assume the findings of the county court judge as the facts of the case.

DIFFICULTIES IN CONNEXION WITH CLAIMS FOR COMPENSATION.

The difficulties in connexion with these cases come under two heads:—

1. The question of entitlement. Is the workmen's incapacity the result of an accident or has it been aggravated by an accident or is it due to some other cause? This is often largely a matter of diagnosis.

In actual fact I imagine that this difficulty arises in only a comparatively small proportion of cases, administered under the Act, as in the majority of cases the accident and the result are obvious. They form, however, a large proportion of the cases which are referred for opinion to surgeons.

2. The question of the duration of incapacity.

This is a matter of a vast difference of opinion between employers and employed. It is often a matter of very considerable difficulty for a conscientious surgeon to decide at what period the injured workman ought to be forced, under the penalty of losing his weekly compensation, to resume his normal employment. It is in my experience comparatively rare to come across cases to which the harsh term of malingering can be applied, but one sees numbers of cases in which a few weeks of inactivity appear to promote an "inertia" and "a work-shyness" which are exceedingly difficult to overcome, and to which the certifying doctor often shrinks, for some months, from applying the drastic remedy of refusing a certificate. It would be impossible to compute the number of working days that are thus lost to the community, or the thousands of pounds thus paid in unnecessary compensation and, what I think is of even greater importance, the damage done to the workman's own morale.

I am not suggesting that this is peculiar to cases which come under the Workmen's Compensation Acts. There is always a startling contrast in the time taken to resume the normal occupation, after accidents incurred at football, hunting, &c., where the responsibility of the incapacity rests with the patient, and the time taken to recover from accidents for which the responsibility rests on others. But it is the enormous number of workmen's compensation cases that renders the matter of so much importance. With a little more encouragement on the part of our profession and, shall I say, some fraternal persuasion, I believe this time could be materially diminished with a considerable effect on the cost of production in our various industries.

SPECIAL DIFFICULTIES IN NERVOUS CASES.

Perhaps of all the pitfalls that beset the surgeon in deciding the question of entitlement, those which arise in connexion with diseases of the nervous system are the most difficult to avoid. Diseases of the nervous system are often insidious in onset, and if the first obvious subjective evidence of an insidious disease, possibly of some standing, should happen to coincide with a slight injury, it would be contrary to the ordinary tendency of human reasoning if the injury and the disease were not regarded in the relationship of cause and effect. The following are a few brief examples of this.

A. B., aged 39, an engine-driver, whose temper for some time had been noticed to be deteriorating, on Oct. 20th, 1924, after a few words with his foreman, slipped and fell on his head while getting off the foot-plate of his engine. He picked himself up and smoked a cigarette, and then noticed that some blood was dripping from a small scalp wound at the back of his head. He attempted to stop the bleeding with a cloth, and lost consciousness. I suggest that he fainted. He was taken to a hospital and regarded as a case of concussion. He became violent and, finally, at the end of three days, left the hospital against advice. He was now labelled cerebral irritation following concussion. He was at home for a fortnight, but behaved so peculiarly that he was taken to the infirmary and remained there until Nov. 20th. On admission to the infirmary he was found to be emotional with hesitating speech, and he suffered from headaches. He also had distinct delusions, and once escaped from the hospital. He was again regarded as a case of cerebral irritation following on the injury to the head.

When seen on Dec. 18th the man stated that he was in perfect health and demanded to return to work. He was tremulous, with indistinct speech, which he attributed to the loss of six teeth in the infirmary. His deep reflexes were increased. His pupils were unequal and inactive to light. There was a small scar, which was not tender, on the right side of his occipital region. At this period it was not difficult to realise that this was a case of general paralysis, and this was afterwards confirmed by a neurologist who, however, also was of opinion that the condition had been accelerated or aggravated by the injury to the head.

The subsequent history of this man is of interest.

In February, 1925, he was admitted into a mental hospital under certificate with marked mental and physical signs of general paralysis of the insane. His blood and cerebrospinal reactions were positive. While in this hospital he was treated with injections of malarial organisms; he was allowed to leave in July, as his mental condition had become normal. He was seen again in March, 1926, when he appeared to be perfectly rational, but his pupils did not react to light and there was still a marked activity of his deep reflexes. This man was seen by a mental expert as late as August of this year, when his mental condition was stated to be satisfactory, but there was still tremor of his hands and of his tongue on protrusion. His pupils did not react to light and his knee-jerks were brisk. The man is now back at work, and is at present driving a small engine in a yard, but he is naturally not allowed on "the road."

Tabes dorsalis is the cause of many difficulties.

In June, 1919, C. D., a man aged 45, was loading up some postbags into a van, when the barrow, on which he was standing, moved, and he twisted his body and fell against the side of the barrow. This happened just as he was coming off duty, and he had finished his work. He did not return to duty the next day, and it was stated that he had strained his back and his abdominal muscles. He returned to work for short intervals during the autumn of that year, but was more often absent, and was always furnished with certificates of "injury to the back muscles, &c." In March, 1920, his employers refused to continue his compensation payment, and the man threatened an action. This did not materialise until 1924. When he was examined for the purposes of the action he stated that he had "lost his strength," and that "his legs gave way," and that he had "pain across his back." His pupils reacted very sluggishly to light, and his knee-jerks could not be obtained. It also transpired that he had been under treatment at a London hospital for four years, and that he was gradually improving. The case came into court and was referred to the medical referee, who decided that it was one of tabes dorsalis, and had no reference to injury.

In this instance the man was undoubtedly as much deceived as were his doctors in the early stages of his illness. (Probably the real villains of the piece were the solicitors, who persisted in the claim in spite of the fact that they produced no medical evidence.)

[A somewhat similar case was here narrated in detail where a syphilitic affection of the central nervous system had first manifested itself three days after a trivial accident.]

A strange case was that of E. F., a vanguard, aged 16, who was seen on Oct. 6th, 1924, and who was then evidently recovering from a right hemiplegia and aphasia. His own statement was that in the previous April (six months before), while lifting an empty petrol tin off a lorry, he slipped and stumbled against the side of the lorry, hurting his right arm and leg. He said nothing about this at the time, but on the next day he went sick and on May 2nd went to the infirmary, where he gradually became paralysed down the right side and also lost the power of speech.

What E. F. forgot to mention was that, previous to the alleged accident, in March he had been admitted to the same infirmary with an obscure febrile disease and headache. He gradually improved, and was discharged on April 14th. He was readmitted on May 2nd, and certainly then told the doctor of the infirmary that he had scraped his knee against the "tailboard of a wagon," but, unfortunately, on this occasion, in order to account for the fact that an alleged abrasion had healed he had had to antedate his accident 10 days. As a matter of actual fact, there was never any evidence of an injury except the boy's own statement, and he had never made any mention of one until he reached the infirmary.

While he was in the infirmary on the second occasion there was a gradually increasing paresis of the right arm and leg, with aphasia, and this gradually cleared up. The Wassermann test gave a negative reaction.

It was not until he had practically recovered that the diagnosis of encephalitis lethargica was made, and I should imagine that was probably the correct one. It would, however, have been an awkward case to have dealt with if the boy had selected an injury, say, to the left side of the head instead of injuring his right arm and leg.

[Another case, which might, perhaps, be explained as one of undiagnosed encephalitis lethargica, was described. The earliest symptom was noted just after a very slight injury, and loss of consciousness, aphasia, and paralysis followed. The patient ultimately recovered.]

A trivial injury is often held to be responsible for symptoms which are afterwards found to be due to the insidious onset of a cerebral tumour. Of this the following case is an example :—

G. H., aged 34, on March 22nd, 1922, while pulling a crate of furniture down from his van fell and struck the ground with his left temple. The crate also fell on him, and caused him to cut his lip. This happened immediately before the dinner hour, and after his meal he resumed his work. Later in the day he reported the accident, but did not go sick, though he went to his doctor and got some medicine. He occasionally felt queer, but it was not until September (seven months afterwards) that he complained of severe and continual headache. He still continued to do his work for over a year, and it was not until December, 1923, when he was attending a hospital for a trivial injury to his wrist, that he came under the observation of a neurologist (one year nine months after).

He then went off duty, and when examined in February, 1924, it was found that he had partial paralysis of the left third, fifth, sixth, seventh, and eighth nerves, pain over the left side of the head, and double vision. There were no symptoms of increased intracranial tension and no optic neuritis. His reflexes were normal, and there was no paralysis of the limbs. Examinations of the blood and cerebro-spinal fluid, and an X ray photograph of the skull revealed nothing abnormal. A diagnosis of a tumour at the base of the brain was made and, as the physician and surgeon in charge of the case were unable to exclude the possibility of injury as a cause, liability was admitted.

In October, 1924, at another hospital, it was thought that he might have an eighth nerve tumour, and his posterior fossa was explored but nothing abnormal was found. The man is, I am glad to say, still alive (Sept. 21st), though he still presents the picture of a tumour at the base of the skull.

Whatever name we may give to it, we have to admit that a certain group of symptoms may follow the *commotio cerebri* which results from the shock of any serious injury, particularly a head injury. Sir Frederick Mott called the condition "traumatic psychasthenia due to a functional disturbance of the brain as an organ of mind." I need scarcely describe the symptoms of a typical case. But it is not over the typical cases that there is any difficulty.

The liability for a typical neurasthenia or psychasthenia following, with no loss of continuity, a straightforward and definite injury has to be admitted, and the only question is to get the man well and back to his work as soon as possible, both for his own and for his employer's sake.

Unfortunately the term neurasthenia has gradually become to be applied to indefinite conditions, often following very trivial and very vague accidents, and these cases present every kind of difficulty.

THE BORDER TERRITORY OF MALINGERING.

In a few cases the distinction between a pathological condition and frank malingering becomes extremely fine. In the majority there appears to be a condition of mental and bodily "inertia" which appears to rob the patient not only of all ambition but of what many of us would regard as ordinary self-respect. Such patients are content to live idle lives, drawing somewhat less than their ordinary pay, rather than make the mental effort necessary to resume their ordinary occupations.

[The point was illustrated by a case of slight injury to a man of poor physique, where careful and repeated examination revealed no organic cause for the symptoms of which he complained. His employers ultimately decided to cease paying his compensation, and he brought the case into court. He produced medical evidence that he was suffering from traumatic neurasthenia, the result of the accident, and a sympathetic county court judge, who quite ignored his medical referee, practically settled the case in his favour by forcing a compromise on the employers.]

L. M., aged 21, who was seen in April, 1925, stated that he was hit on the right side of the lower jaw by the handle of a barrow on May 16th, 1924, nearly a year before. He said that he remembered nothing of the accident, but that he was assisted to an ambulance station and then went to a hospital, but was not detained. He remained away from work until August, when he was given light work, on a certificate from his doctor that he was suffering from "traumatic neurasthenia." L. M. was a sturdy-looking man, 5 ft. 4 in. in height and 9 st. 10 lb. in weight. He thought that he had gained slightly in weight since the accident. He complained that occasionally he had "a feeling" the nature of which he was unable to explain, which at times prevented him from stepping on to a train to go to his work. It did not occur to him to walk there, a distance of about two miles. He also suffered from loss of memory, but could not give many examples of this, except occasional inability to express himself or to give an account of his doings. He did not think that he had ever forgotten to have a meal. His father, who was 48 years of age, had not worked for some time owing to "chest trouble." The mother did not go out to work, and the family was in receipt of Poor-law relief.

Beyond a slight tremor of his hands, L. M. presented nothing abnormal. The jaw itself, the original seat of injury, had never given rise to any trouble; he had suffered an injury to the jaw of a severity no greater than is constantly sustained on any football field and which does not, as a rule, prevent the player from finishing the game after a short rest. But for the intervention of a sympathetic ambulance man I doubt whether it would have occurred to L. M. to have gone to a hospital. The hospital authorities evidently thought little of his injuries, and allowed him to go home.

Circumstances in the shape of a poor home and the Workmen's Compensation Act led L. M., a youth of low mentality and a lazy nature, into a life of semi-invalidism. One could not say truthfully that he was malingering. There was the slight tremor of the hands, and his pulse-rate was raised to 100 throughout an interview of over half an hour. He was, however, undoubtedly making the most of a very slight disability. With a minimum of resolution on his part he could have undertaken any work for which he was mentally and physically fitted. He had unfortunately been labelled with the term neurasthenia, the nature of which had apparently been indicated to him, and he was content to remain neurasthenic so long as the stimulus of want did not force him to do a decent day's work. It is cases like this which do not present the pleasantest aspects of the Workmen's Compensation Act.

THE ASSOCIATION OF ACCIDENT WITH TUBERCULOSIS.

But it is not only these obscure nervous cases which present difficulties with regard to entitlement. It must be within the experience of all of us that a large proportion of cases of surgical tuberculosis, particularly in the case of joints and the spine, are by the public supposed to originate with an injury. In fact, this is not confined to surgical cases, and I remember many years ago, when I was a resident at a children's hospital, how all the cases of tuberculous meningitis appeared to have arisen as the result of injuries. Investigation showed in most cases that the injury was an after-thought, and often the only evidence of it was the fact that the child had something wrong with its head. So deeply rooted in the public mind is the belief that disease must be caused by something outside the patient, and the easiest cause to invoke is usually an injury.

N. O., aged 34, a weakly-looking man, was seen on Dec. 29th, 1923. He stated that on Nov. 30th, while standing "astride a dyke," and shovelling out soil, he struck his left testicle with the handle of his shovel. He continued his work for the remainder of the day, some six or seven hours. Since then the organ has remained tender and swollen. The epididymis was enlarged and indurated, and the vas was nodular. The testicle itself did not appear to be affected. The case was obviously one of tuberculous epididymitis, and it was not considered that the accident a month before had much to do with its causation. The man, however, was advised otherwise, and was taken into a hospital largely, if not altogether, supported by trades-union funds. The case was there regarded as a hæmatoma of the testicle, as the result of injury, until it was removed in May, when it presented all the features of an advanced case of tuberculosis of the testicle. The man brought an action against his employers in November, 1924, which was resisted on the ground that the accident, which was of a trivial nature, had merely called the man's attention to what was already present. The judge, however, sitting with a medical assessor, took the view that the accident of Nov. 30th had aggravated the condition, which may have already been present, and the man obtained his compensation. I have since learnt that he has undergone another slight strain, and that a similar operation has had to be performed on the right side.

The question of the relation of injury to tuberculous epididymitis is interesting. I have never myself seen tubercle follow a gross injury to the testicle, such an injury, for instance, as produces a hæmatocele. In all the cases I have seen of tuberculous testicle, of which injury has been alleged to be the cause, the injury has been always either very slight, or of a nature so vague and shadowy as to raise doubts as to its existence.

Two of my patients were convinced that the tuberculous epididymitis for which they were admitted to hospital was caused by bracing up their trousers too tightly, and I was never able to persuade one of them that this probably had had nothing to do with it and had merely demonstrated to him that he had a tender organ. I should like to hear the experiences of other surgeons on this point.

ACCIDENTS IN THE SYPHILITIC.

Somewhat similar to this, though the disease in question was different, was the case of P. Q., a travelling ticket collector, who was seen in May, 1925. He gave a history of a parcel falling on his shoulder and then hitting his right testicle in May, 1919. He continued to work for a week, although the organ was swollen. He then went off duty until August, and finally the testicle was in October, 1919, diagnosed at a hospital in London as malignant and removed. He resumed work in December, and continued to do so until November, 1923, when he fell between a moving train and the platform and fractured some ribs. He had not worked since then. In the meanwhile his liver had enlarged.

The case was regarded as one of malignant disease of the liver, secondary to a malignant testicle. The question for decision was whether an injury could be held responsible for malignant disease of the testicle. Fortunately this very difficult question did not have to be answered.

Further investigation revealed the fact that the testicle removed in 1919 proved, after removal, to be a gumma. P. Q.'s blood gave a positive Wassermann reaction, and he was also found to have a syphilitic ulceration of his larynx. Under appropriate treatment he improved rapidly, and was glad to receive compensation for the enlargement of his liver, which was rightly held to have been aggravated by the injury in 1923 to his ribs and chest. He is still alive and in comparatively good health.

It is quite impossible to lay down any general rule about the relationship of tuberculous joints and injury. Each case must be decided on its merits, but where there is a definite, well-proved injury to the joint in question, then I think it is impossible to resist the contention that the condition of the joint, if not caused by, may have been aggravated by the injury.

JOINT INJURIES AND OSTEOARTHRITIS.

But if there is difficulty about tuberculous joints that difficulty is increased tenfold when we come to cases of osteoarthritis. The condition is extremely common amongst manual workers above a certain age, a fact which may, perhaps, suggest that repeated and slight injuries to the joints may play a part in the causation. It is also a fact that amongst men of this class one sees an enormous number of septic mouths. The disease is insidious in its origin, and consequently the first intimation a man may have that there is anything wrong with his joint is on the occasion of a trivial injury to it. It would be asking too much of human nature if he did not attribute to the injury any subsequent disability of the joint.

Not an uncommon example is that of an elderly workman who has continued to do his routine work without it being noticed either by himself or by others how stiff and awkward he was becoming. Some trivial accident lays him up and once having got out of his stride he finds himself unable to resume work. The following case illustrates this point:—

R. S., seen on June 11th of this year; 65 years of age and 47 years in one employment. On March 12th a bundle of iron pipes which he was carrying fell on his insteps, chiefly on his right. He left his work and walked some distance home. By his doctor's advice he remained in bed for two or three weeks. Since then he has been getting about, but always in pain. He now has osteoarthritis of both knee-joints, sufficiently advanced to reduce him to the condition of a cripple. Nothing could be found wrong with his feet, although he asserted that he was suffering "agony" in both of them. It was almost pathetic to watch him attempting to locate in his feet the pain which he undoubtedly suffered in his knees. The slightest passive movement of the latter was painful, while his ankles could be moved with impunity. His attempts to reverse these facts were almost heroic. It was quite obvious that a weight falling on the insteps in March could not produce a crippling deformity of the knees by June. The man was, in my opinion, perfectly straightforward, he was genuinely puzzled, and could sum up the situation only by repeating "that he was not like it before the accident." Naturally, as it was on his feet that the weight dropped, there, he reasoned, should be the pain. It is my belief that already in March he had advanced osteoarthritis of both knee-joints. He was, however, able to carry on, perhaps slowly and stiffly. The accident threw him out of his stride, and was, therefore, an aggravation of his condition.

The following case illustrates the difficulties that a very cunning or a stupid man may introduce into what should have been a straightforward case:—

T. U., a carriage cleaner, aged 63, was seen in July, 1923. He stated that in August, 1919 (four years previously), while cleaning a coach he fell into a pit 4 ft. deep and hurt his left arm and right knee. That he was laid up for eight weeks until Oct. 18th, and was paid compensation for that period. That he resumed work until Dec. 29th, 1919, when he went sick with "influenza," and from that period, December, 1919, he had not worked again. While he was laid up with "influenza" his right knee and then his left became swollen and painful, and had since remained so.

When seen in 1923 there was marked deformity of both knees, the joints were distended with fluid, and the bony surfaces, forming the joint, were distorted by large masses of new bone formation. There was also marked lateral mobility. Both joints were comparatively painless and presented a typical picture of the joints described by Charcot. Neither then nor at any time could any evidence of disease of the central nervous system be detected, and it was ascertained that a Wassermann test, made at the hospital he was attending in 1922, had proved negative. By a coincidence, I had seen this man at the examination hall some months previously, when the condition of his joints and the

complete absence of any evidence of disease of his central nervous system had aroused comment.

At first sight the case seemed to be straightforward from a compensation point of view. Whatever one may have thought of the nature of the arthritis, there seemed to have been more or less direct continuity from the time of the accident until the commencement of the knee condition, and it was advised that liability should be admitted. What, however, T. U. had omitted to mention was that after resuming work in October, 1919, he worked for 14 months until December, 1920, before going sick with influenza. The certificates given by his doctor in 1921 were for influenza until February, when rheumatism as well as influenza was mentioned, and finally arthritis in March. The case, therefore, resolved itself into that of a man who had an injury, chiefly to his shoulder, in August, 1919. There was then no mention of his knee. He resumed work in October, 1919, and continued to do his ordinary full work until Dec. 29th, 1920 (14 months), when he went sick with a febrile disease. While he was laid up during February and March, 1921, an obscure condition of his knee-joints developed, resembling an arthropathy. There was, therefore, a period of 18 months between the date of the accident and the first evidence, beyond T. U.'s uncorroborated statement, of any disease of the knee-joint.

In spite of this the case was taken up by the man's trade-union and brought into court, when T. U. finally had to admit that in his previous statements he had omitted a year. The case was decided in favour of the employer. The union, however, produced medical evidence that the man's condition was due to the injury in August, 1919.

DIFFICULTIES IN CONNEXION WITH SPRAINS AND FRACTURES.

The expressions "strained," "ruptured," and "contused muscles" are constantly seen on certificates given in connexion with accident cases, and it is wonderful for how long a time a strained or partially ruptured muscle may continue to give trouble, particularly when it is in the back. The following case is fairly illustrative of this class of injury.

V. W., aged 41, while working in a railway cutting in September, 1920, fell or rolled down a bank about 10–12 ft. high and hurt his back. He was taken home on an ambulance and seen by a doctor who said, according to V. W., that he had "twisted or sprained his vertebræ." He was laid up for eight weeks (six of which were in bed). He then resumed light work, but could not use a shovel or wheel a barrow. He was appointed as look-out man, and merely had to warn the gang of an approaching train.

In May, 1923, he was admitted into a London hospital, and some tenderness and rigidity of his back muscles was noted. These muscles were twice stretched under an anæsthetic. According to V. W. and his solicitor, this operation was for the purpose of replacing a displaced vertebra. He was discharged from the hospital in June as cured. He had never, however, returned to work, even to light work again. When he was seen in February, 1924 (three and a half years after the accident), he was a healthy-looking muscular man. He stated that his back began to ache in the afternoon, and became weak towards night. He was unable to lift anything. There was no tenderness nor rigidity of the back muscles, and the movements of the back were perfect. He could do exercises that would be the envy of the majority of men over 40. He had practised these exercises since leaving the hospital, and had evidently done so with enthusiasm. A thorough examination revealed no evidence of ill-health.

V. W. very possibly ruptured some fibres of his back muscles at the time of his accident in 1920. With a little determination on his part, aided possibly by some forced movements of his back, he should have been able to return to work in a few weeks. He, however, nursed his back and refused to use it. Consequently, two and a half years afterwards, a surgeon had to do under an anæsthetic what V. W. could have done for himself within the first few weeks of the accident.

He had in the meanwhile acquired a habit of leisure which he was unwilling to disturb. His wife took in lodgers. They had no children, and he was comfortable and well looked after. He went to bed at 10 P.M. and arose at 9 A.M. A contrast to the ordinary life of a labourer on the line. This idyllic existence ceased, however, when his employers, on advice, refused to continue to pay his compensation, and the man resumed his normal work.

There is no difficulty about entitlement with regard to a fracture; the difficulty here arises as to the date of the man's return to his regular employment. Probably few of us, who are engaged in hospital practice, realise the length of time that elapses before a workman, who has broken a limb, particularly one of the lower limbs, returns to his normal work. His fracture may do well and the surgeon is pleased with the union and with the alignment. The patient passes on to the surgical out-patient department or to the orthopædic department, and everyone is satisfied with the return of function, as the result of massage, exercises, &c. Possibly some months afterwards an energetic surgeon or house surgeon may send for him and be told that he has returned to work. Too often he has gone back to "light work," and may remain on that for one, two, or three years or more. Sometimes he obtains his certificates from the hospital, but more often from his panel doctor, who did not have the opportunity of watching the case from the beginning.

As a rule, light work is not what may be regarded as economic labour. Sweepers, watchmen, mess-waiters, lift boys (who are no longer boys) are the usual type of "light workers." They are being paid a wage which, while it never exceeds 30*s.* per week, equals half the wage of the employment at the time of accident plus half the difference between this and the wages they would have received had they remained in their old occupation.

Fractures in the region of the ankle-joint are the most typical examples of this. I remember nearly 20 years ago the late Mr. Clinton Dent saying that seldom, if ever, did a policeman who had sustained a Pott's fracture return to his normal duties. These are two common instances.

A man, aged 54, sustained a fracture in the region of the right ankle in July, 1921. He was seen in March, 1924 (nearly three years afterwards), when he displayed a result of which any surgeon might be reasonably proud, and there was no stiffness of the joint. There was, however, the slightest degree of flat-foot. He had been told to continue the exercises he had learned in hospital, but his clumsiness in performing them at once proclaimed the fact that he had not done so.

The next case, aged 47, was seen in June, 1925. Fracture of left ankle in March, 1923. So far as the fracture was concerned the result was excellent. There was no deformity of the ankle, and the movements of the joint were good. There was, however, a slight degree of flat-foot and the muscles of the calf were somewhat wasted. He had been taught to do exercises at the hospital, but had not done any for some months.

I could multiply these cases ad libitum. Good anatomical results, no stiffness of the joint, and everything possible done at the hospital to promote the recovery of function. But numbers of these men leave the hospital and spend their time standing and limping about and seldom, if ever, make any attempt to continue the exercises they were taught to do. There is, of course, in addition to these the usual proportion of bad results of fractures. These may be regarded as inevitable as the result of the original violence. Occasionally, too, one comes across a case where no attempt was made at the hospital to restore the function of the limb after union has taken place. But there remains over and above these a number of men to whom function appears to have been restored, and yet who do not possess the will to make economic use of it.

Our ordinary hospitals appear to have done what is usually regarded as their duty. They are chiefly concerned with the humane endeavour to save lives and to restore function to damaged limbs. Whether the man makes any economic use of his restored function does not appear to be any concern of theirs. Industry would seem to require another kind of hospital, or what might be called an "after-care centre," where by constant personal supervision and encouragement these men can be induced to overcome the apparent diffidence they have in their own powers. Hospitals of this sort were initiated towards the latter part of the late war where men, by means of workshops and other devices, were taught to make use of their already restored powers and were, by encouragement and precept, inculcated with the will to return to their duties. There is something wrong when we find men, three or four years after a comparatively trivial injury to the muscles of the back

or a straightforward fracture of the leg, still unable or unwilling to take their proper place in life.

I have touched but slightly on the fringe of a vast subject. Many obvious subjects for discussion, for instance, hernia, I have not mentioned.

BLOOD TRANSFUSION IN CHILDREN'S PRACTICE.

BY C. HOPE CARLTON, M.CH. OXF., F.R.C.S. ENG.,
LATE RESIDENT SURGEON, HOSPITAL FOR SICK CHILDREN, TORONTO.

THIS paper is an attempt to estimate the place of blood transfusion in the treatment of sick children. During the year 1925 I gave a large proportion of some 600 transfusions at the Hospital for Sick Children, Toronto, with results excellent in some cases, inconclusive in others. While my conclusions are based on these observations, I submit also statistical evidence to serve as a basis of comparison. Statistics are no substitute for clinical judgment, but they may confirm it or, by conflicting with it, they may direct attention to some unsuspected factor. The technique of the transfusion was the same throughout the year; it has been standardised for several years past at this hospital. The possibility of a technical breakdown is, therefore, practically eliminated.

THE BLOOD TRANSFUSION OPERATION.

To be successful this operation must be performed with the same care and under the same conditions as any other major operation.

The donor, wearing sterile cap and gown, lies upon an operating table with his arm on an arm-board placed at right angles to his trunk. The elbow is cleaned all over with absolute alcohol and covered with sterile towels, leaving the antecubital fossa exposed. A folded towel under the olecranon ensures hyperextension. On a second table lies the recipient with his feet near the donor's arm. The foot which is not being used is made fast with a webbing strap and the other is held by a nurse, who rotates it outwards so as to expose the internal saphenous vein at the ankle. The patient's foot and the nurse's hands are cleaned with absolute alcohol and covered with sterile towels, a circle of skin being left exposed round the internal malleolus. Two operators are necessary, one by the donor's arm and the other by the recipient's foot. They must be within reach of each other and of the instrument table, and both they and the instrument nurse must be surgically clean and wear cap, gown, mask, and gloves.

The first step is to examine the blood-grouping certificates issued by the laboratory and to make certain that they refer to the donor and recipient present and that these are of the same group. (Universal donors are never used.)

The recipient's operator, using a fine needle and 0·5 per cent. novocaine, raises a wheal over the internal saphenous vein, or, if the vein is not visible through the skin, over the ankle in front of the internal malleolus. An incision half an inch long is made at right angles to the vein and opened up with the points of fine scissors. The vein is identified and two fine plain catgut ligatures passed under it. The ligature nearer the heel is tied and artery forceps clipped on its loose ends to serve as a retractor. The other ligature is looped around the vein with a surgeon's knot, but is not drawn tight. The half inch of vein between the two ligatures is nicked in an upward direction with a pair of fine scissors; the transfusion needle is pushed through the nick and up the vein and the loose ligature tightened round it.

These transfusion needles are made of gold in various sizes. Their distal ends are smooth, having a short bevel, whilst their proximal ends are shouldered and take an adapter, to which is attached two inches of rubber tubing. The syringes used for transfusion are all-glass Luer syringes, graduated to 20 c.cm. and holding 25 c.cm. They are lubricated with sterile liquid paraffin.

To make sure the needle is actually in the vein a Luer syringe containing 5 per cent. glucose is attached by inserting its nozzle in the rubber tube and the plunger gently depressed. If the solution runs with difficulty and raises a subcutaneous swelling the needle must be withdrawn and reintroduced.

When fluid enters the vein easily the operation on the donor is commenced. To withdraw blood from the donor a 4 ft. piece of sterile flannel is wetted, passed round the upper third of his arm, tightened, and tied once. He makes the veins of his forearm stand out by clenching his fist and a wheal is raised with 0·5 per cent. novocaine over the most prominent vein. The skin is incised by transfixion through this wheal and the needle is passed through the incision into the vein. Were the needle pushed straight through the skin it might transfix both walls of the vein. The blood is withdrawn into an all-glass Luer syringe, graduated to 20 c.cm., the plunger of which has been lubricated with paraffin. The syringe is connected by two inches of rubber tubing to a metal adapter which fits the shoulder of the needle. The needle is made of rustless steel; its length is 4 in. and its calibre 2 mm. At its proximal end it has a square shield, the straight edge of which rests on the skin and prevents rotation. At its point it has a short sharp bevel. It is inserted into the donor's vein as follows.

The syringe, rubber tube, adapter, and needle are coupled up. The operator holds the needle between the thumb and first two fingers of the right hand and inserts the point through the skin incision, so that the needle lies at a slight angle to the vein. Steadying the skin by the side of the needle with his left thumb and forefinger, and holding the needle with his right thumb and forefinger, he pushes the point into the vein. At the moment of entry blood appears in the syringe. He now takes hold of the needle with his left thumb and forefinger and continues to hold it in this way throughout the operation. When the syringe is filled it is disconnected and handed to the other operator, who injects the blood into the recipient at the ankle. At the same time the instrument nurse hands another glass syringe to the donor's operator. There are five syringes in circulation between donor, recipient, and instrument nurse. The instrument nurse washes each syringe through with normal saline as she receives it and dips the end of the plunger in sterile paraffin. When the operation is complete the needle in the recipient's vein is withdrawn, the second ligature tightened, the wound closed, and a bandage applied. At the same time the donor's tourniquet is relaxed, the needle withdrawn, a pad placed on the wound, and the elbow flexed. Oozing soon stops and a bandage is then applied.

In my experience there is no better method of transfusing blood than this; it is simple, clean, and swift. The patient receives whole blood, yet clotting is rare. It can only occur in the needle, the rubber tube, or the syringe, any one of which is quickly replaced by a spare from the instrument table. I have often seen eight transfusions carried out without a hitch in two hours.

Infants and young children can safely take 15 c.cm. of intravenous fluid per pound body-weight, and the time allowed for this is five to ten minutes. In thoracic disease not more than 10 c.cm. per pound body-weight should be given, and that in not less than 25 minutes. This type of case is rare, as transfusion is of little value in thoracic disease.

Modifications of the Transfusion Operation.

1. *The use of citrated instead of whole blood.*

This is necessary when donor and recipient must be kept apart, as in acute infectious disease, and also if the recipient has a blood infection. The donor enters the operating room first and his blood is withdrawn in the ordinary way, but with 20 c.cm. syringes each already containing 2 c.cm. of 4 per cent. sodium citrate solution. The resulting dilution of citrate (0·4 per cent.) is sufficient to prevent clotting. The syringes are emptied into a sterile vessel surrounded with warm water. When sufficient blood has been collected the donor leaves and the recipient is brought in. The citrated blood is then injected by the usual method.

2. *The exsanguinating-transfusion operation.*

This operation, introduced by the late Dr. Bruce Robertson, of Toronto, aims at the removal of supposedly toxic blood and its simultaneous replacement by blood from healthy donors.

60 c.cm. per pound body-weight of the patient is collected by the citrate method and set aside in warmed vessels. The patient is brought in and a needle inserted at the ankle. One operator takes charge of this and the subsequent transfusion; the other drapes the groin and cuts down on the upper end of the opposite saphenous vein, exposing it as in Trendelenburg's operation for varicosity. The skin is infiltrated with 0·5 per cent. novocaine and incised, the fatty tissues are separated, and the vein identified at the level of the deep fascia over the adductor longus. Two ligatures are passed round it and the lower one is tied and left long to serve as a retractor. The upper ligature is looped round the vein. Between the ligatures the vein is nicked and a long steel needle of uniform thickness with a blunted distal end is inserted and slipped onwards until its point lies in the external iliac vein, when blood will flow from it. It should

be smeared with paraffin to make it enter easily. A 20 c.cm. Luer syringe containing 2 c.cm. of 4 per cent. sodium citrate is connected to the needle, and as one syringe is filled another is put in its place.

The two operators now commence the exsanguinating transfusion. As blood is withdrawn from the external iliac vein of one leg fresh blood is introduced at the opposite ankle. The exsanguinating operator sets the pace, since it is harder to withdraw blood than to inject it. An assistant keeps a written record of the amount of blood given and withdrawn, and calls out the figures at frequent intervals. It is essential that these figures be recorded accurately and announced audibly, to enable the operators to realise at once if any variation occurs in the total volume of the circulating blood. Rapid variations may lead to collapse on the one hand or cardiac embarrassment on the other.

At the end of the operation the needles are withdrawn, the veins tied off, and the skin sewn up.

Reactions during Blood Transfusion.

Reactions are almost unknown if the amount given and the time taken are kept within the limits laid down. They may possibly occur in premature or very young babies, and the early signs are cyanosis, distension of the veins of the neck, and lividity of the lips and finger-nails. Transfusion should be stopped and the child immersed in a mustard bath for 30 seconds and then rubbed briskly. Five minims of 0·001 adrenalin are given and the child is supported in a sitting position. If this does not give relief, blood is withdrawn from the longitudinal sinus by inserting a guarded needle through the anterior fontanelle.

RESULTS OF BLOOD TRANSFUSION IN CHILDREN.

1. *Accidental Shock.*—Blood transfusion is the most potent single remedy for this condition, as it restores the child when the commoner measures fail. Seven out of eight children so treated recovered from the initial shock, although their injuries were so severe that five ultimately died.

2. *Post-operative Shock.*—Post-operative transfusion increases the chance of success in certain emergency operations, and is an invaluable stand-by in operations of election which may unexpectedly cause death by shock. After craniotomy it is especially useful. In this series three children out of four developed a regular pulse and good colour and recovered consciousness, although before transfusion they had shown few signs of life. The repair of hare-lip, undertaken as it is in very young infants, may be complicated by shock; this happened on ten occasions. Transfusion improved them all and they made good recoveries. Twenty-two out of 24 infants who underwent pyloroplasty for pyloric stenosis improved after transfusion, and 20 made a good recovery. It was necessary to transfuse 14 children after operation for intussusception; all but one of these appeared better for it, though five ultimately died. On the other hand, transfusion was of no value after rib resection for empyema.

3. *Prematurity.*—Forty-eight premature infants received 73 transfusions, in 60 per cent. of which good results followed. A transfusion should be given on the seventh day of life if the infant is not gaining on a liberal diet.

4. *Hæmorrhage of the Newly Born.*—The commonest sites of bleeding are the rectum, umbilicus, and stomach. Transfusion is not a sovereign remedy but is the best available. It arrested the bleeding in 11 infants out of 17, and the clotting time in these 11 was found to be reduced by one-half.

5. *Septicæmia.*—Our observations hold out little hope that blood transfusion will prove an efficient weapon against septicæmia. Of 34 children from whose blood micro-organisms had been grown six got better and 28 died. The actual organisms were as follows:—

	Cases.	Deaths.
Staphylococcus aureus ..	12	11
Streptococcus hæmolyticus	13	10
Pneumococcus	6	5
Bacillus coli	2	1
Streptococcus viridans ..	1	1

Out of 50 blood transfusions only 17 did the patient any good. Exsanguinating transfusions were of no more use than simple transfusions.

The details of the six cases which recovered are as follows:—

(*a*) A streptococcal septicæmia following a compound fracture. A simple transfusion on the tenth day of the disease was followed by improvement in the appearance of the wound.

(*b*) A streptococcal septicæmia two days after opening up an acutely inflamed bone. No benefit followed exsanguination, although the child ultimately recovered.

(*c*) A streptococcal septicæmia four days after opening up a bone. An exsanguination lowered the temperature and improved the colour and appetite.

(*d*) A coliform septicæmia following umbilical sepsis. A simple transfusion followed by an exsanguination caused great improvement.

(*e*) A pneumococcal septicæmia following peritonitis, pneumonia, and empyema. The abdomen was drained and the child exsanguinated. Four days later the improvement was considerable.

(*f*) A staphylococcal and coliform septicæmia in a premature infant. Great improvement followed exsanguination.

As far as can be judged from these observations blood transfusion is not a remedy for active septicæmia. However, it does not make the patient worse, and there is always the hope that the solution may lie in some future modification of it.

6. *Tissue Infections.*—This group includes children who suffered from acute infection of one or more organs, but whose blood did not contain demonstrable organisms. That these were nevertheless often present is suggested by the results of blood transfusion, which were almost as unsatisfactory as in septicæmia. Five out of 11 children suffering from erysipelas died after receiving one or more exsanguinating transfusions without any benefit. A simple transfusion assisted the fading of the rash in the seven who recovered, while an exsanguinating transfusion brought down the temperature.

In the treatment of pneumonia little benefit was observed from blood transfusion. The actual operative danger of cardiac embarrassment was avoided by giving very slowly not more than 10 c.cm. of blood per pound body-weight. The only cases of pneumonia benefited by transfusion were already convalescent. In the earlier stages of broncho-pneumonia no improvement was seen in 29 out of 33 children transfused, while in lobar pneumonia the results were very little better. Transfusion has little value in meningitis, whether cerebro-spinal, acute purulent, influenzal, or tuberculous. All nine cases died. In the treatment of cellulitis of the cancrum oris type transfusion did little good and all the patients died. In general peritonitis only one patient out of seven treated by blood transfusion appeared any better; he, however, recovered. Far better results are obtained from continuous intravenous saline, now that a satisfactory apparatus has been devised for slow administration over several days. In pyelonephritis and in sepsis of the newly-born blood transfusion was of slight value. In acute mastoiditis (in one case accompanied by lateral sinus thrombosis) the results of transfusion were very good, but it is difficult to generalise from three cases.

7. *Burns and Scalds.*—So valuable is blood transfusion in these accidents that it should be the rule to group the blood of the friends as soon as a burned child arrives at the hospital. Their blood may be needed for two purposes. The first is to combat the shock of the burn within the first six hours; the result is often dramatic. The second purpose is not so widely understood; attention was called to it by the late Dr. Bruce Robertson, of Toronto. It is to counteract the toxæmia which a burnt child frequently develops. The onset is from 24 to 96 hours after the burn, and the symptoms are: (1) a sudden and rapid rise in temperature, perhaps six degrees in four hours; (2) a corresponding rise in pulse-rate; (3) muscular twitching and perhaps convulsions; (4) vomiting; (5) drowsiness or irritability. This secondary toxæmia is less often seen than it used to be owing to the inclusion in modern treatment of abundant administration of fluid and the selective action of the tannic acid spray (Davidson).

The treatment advised is an immediate exsanguinating transfusion, followed by a second one if the temperature does not fall within 24 hours. All the six children observed who developed toxæmia and received this treatment showed a rapid fall of temperature and mental improvement; muscular twitchings and vomiting ceased. Five of the six recovered and left the hospital. A burnt child has three dangers to overcome before convalescence—shock in the first 12 hours, toxæmia from the second to the fourth day, and sepsis after the first week. Against the first two dangers blood transfusion and the tannic acid spray are effective safeguards, but for the third little can be done and bad cases terminate in ten days.

8. *Acidosis.*—This is a common complication of the infections of childhood and infancy. Clinically, there is drowsiness with acetone in the breath and urine. The respiration is shallow and each inspiration is followed by a pause. Of the 17 children observed 14 were treated successfully by simple transfusion.

9. *Nutritional Disturbances of Infancy*—Transfusion benefits many children who do not respond to modifications of diet and to interstitial or intravenous glucose and saline. These patients may be divided into four groups :—

Group I.: Infants who fail to do well but are not acutely ill. These may be underfed or overfed breast babies, or bottle babies getting too much fat. Out of 16 infants who were losing weight 14 began to gain after transfusion, while appetite improved in 10 out of 12. Vomiting nearly always yielded to transfusion.

Group II.: Marasmic babies who are emaciated, subnormal in temperature, and liable to intercurrent infections. Of a batch of 75 of these, three-fifths gained in weight and about one-half ultimately got well after transfusion.

Group III.: Summer diarrhœa. Of 21 infants treated, two-thirds were improved and about three-quarters ultimately got well.

Group IV.: Acute intestinal intoxication. This is a much more serious condition than summer diarrhœa. Although diarrhœa and vomiting are frequently present, the outstanding diagnostic features are drowsiness and tissue dehydration. The onset is sudden, with great collapse, and often with muscular twitchings and convulsions. The complaint is common towards the close of a hot, dry summer and is often dangerous. In my judgment a simple blood transfusion should always be given. Of 139 infants who received 179 simple transfusions nearly 70 per cent. were improved, and the drowsiness, vomiting, and diarrhœa were relieved in more than 60 per cent. Forty-one exsanguinating transfusions were carried out, but I consider that the simple operations are as effective. The mortality among patients treated by transfusion was 37 per cent., considerably less than that among patients treated by other methods.

10. *Acute Infectious Diarrhœa.*—This is due to a specific bacterial infection of the intestine. The onset is sudden, with pyrexia, diarrhœa, and vomiting, which are followed by intense dehydration and collapse. There were only seven cases in our series, and three of them died. Improvement followed four out of eight simple transfusions, and all of three exsanguinating transfusions.

One particularly striking case was a boy of 12 who had had a *B. coli* enteritis for 18 hours and in whom it was difficult to detect any sign of life on admission. After an exsanguinating transfusion he looked better and ultimately recovered.

11. *Hæmorrhage.*—Transfusion a uniform success.

12. *Hæmophilia.*—Bleeding may be arrested by blood transfusion more than once in the same patient. Transfusion was successfully employed in five cases, but in three of them it had to be repeated.

13. *Secondary Anæmia.*—Clinical improvement often follows transfusion for anæmia due to chronic infection of the tonsils or kidneys. No improvement occurred in the anæmia of chronic endocarditis.

14. *Purpura.*—Temporary benefit followed transfusion in thrombocytopænic purpura, and it was a valuable preliminary to splenectomy in three cases. In hæmorrhagic purpura of uncertain type it was used three times with little benefit.

15. *Congenital Syphilis.*—Six children receiving the usual antiluetic treatment were transfused without apparent improvement.

Summary.

1. The transfusion of whole blood by means of glass syringes is an easy and successful operation which may be performed even on the newly born. 2. As a combatant of shock and a corrector of hæmorrhage it is a valuable routine adjunct to many operations of childhood. 3. It guards a newly-born child against the dangers of prematurity or hæmorrhage. 4. It may save the life of a child suffering from burns. 5. It is an aid to the treatment of the metabolic toxæmias of infancy.

In conclusion, I wish to express to Dr. W. Edward Gallie, the surgeon-in-chief, and to the other members of the surgical staff of the Hospital for Sick Children, Toronto, my gratitude for their instruction and for the opportunities they gave me of studying patients under their care and of inspecting the records. I wish also to thank Dr. C. F. W. Hames, the resident physician, for his help in assessing the results of transfusion on the metabolic toxæmias of infancy.

A NOTE ON THE MICROSCOPIC APPEARANCES OF THE SPINAL CORD IN TETANUS.

BY SARAH H. NELSON, M.B., CH.B. GLASG.,
MC CUNN RESEARCH SCHOLAR IN THE UNIVERSITY OF GLASGOW.

(*From the Department of Pathology, Royal Infirmary.*)

RECENT literature on the histology of the nervous system in tetanus reveals great diversity of opinion regarding the changes which are met with in the spinal cord in that disease. In none of the published cases have the posterior root ganglia been examined, and as I have found definite changes in these ganglia, I venture to publish this account of the histological appearances of the cord in a single case of tetanus.

Clinical History.—E. S., aged 16, was admitted to the Glasgow Royal Infirmary under the care of Mr. John Patrick on June 3rd, 1924. Sixteen days previously she had received a puncture wound on the sole of the left foot from a dirty nail out of a packing case. An abscess formed at the seat of injury, but resolved under treatment and appeared to be soundly healed. A fortnight later the patient felt stiff and her stiffness increased. On admission to hospital two days later a distinct but not marked risus sardonicus was present. The jaws were not separable by more than half an inch. The neck was rigid and there was rigidity of the arms with slight flexion at the elbow-joints. The body was very rigid and the normal lumbar curvature exaggerated. The legs were rigid, extended at the ankle-joints, and the feet arched. Occasional tremors affected the trunk and extremities, but were not sufficiently marked nor of long enough duration to constitute definite convulsions. Temperature 100° F., pulse 108, respirations 30. Antitetanic serum was given subcutaneously, intravenously, and intrathecally during her three days' residence in hospital, but the patient's condition did not improve. After the last administration of antitoxic serum, which was intrathecal, the patient complained of pain in the left leg and a frontal headache. Swallowing and articulation became difficult. There were occasional tremors and spasms and there was marked rigidity of the whole body. The temperature rose to 102·4°, pulse 158, respirations 50, before death, which took place on June 6th, the fifth day of the illness. So far as could be ascertained, the temperature during the last three days of life ranged from 100° to 102°.

Post-mortem Examination (June 6th).—Trismus was present. The face and neck showed marked post-mortem lividity. The right side of the heart was dilated and cloudy swelling of the whole myocardium was present. There was some fatty degeneration of the intima of the aorta and several punctiform hæmorrhages were present in the anterior mediastinum. The lungs showed subpleural hæmorrhages with extreme congestion of their substance, and the lower lobes were very œdematous. The liver was congested and exhibited marked cloudy swelling. Some unusually large patches of subcapsular fatty degeneration were evident. The spleen was larger than normal and congested. The kidneys showed congestion and cloudy swelling. On microscopical examination the wound revealed pyogenic granula-

tion tissue, but no organisms could be demonstrated. Cultures from the wound were not made. The thecal canal showed an apparent excess of cerebro-spinal fluid, but no definite changes were noted macroscopically in the spinal cord. Unfortunately, the brain was not kept.

The cord was fixed in alcohol. Sections were prepared by the paraffin process from the cervical, dorsal, lumbar, and sacral regions of the cord, and several of the spinal ganglia of the posterior roots were also examined, including those of the fifth lumbar and first sacral segments. The following staining methods were employed: (1) hæmalum and eosin; (2) Heidenhain's hæmatoxylin and Van Gieson; (3) acid hæmatoxylin; (4) toluidin blue for Nissl's bodies; and (5) Victoria blue for neuroglia (Anglade and Morel, Anderson's modification).

Microscopical Examination.—The vessels of the pia mater were congested, as also were some of the vessels between the bundles of nerves entering the spinal ganglia. There was dilatation and congestion of the vessels of the cord and hæmorrhages were seen, especially in the posterior columns. There was no perivascular infiltration and no overgrowth of neuroglia. Plasma cells were not present, and there was no degeneration of the tracts of the white matter.

The cells of the anterior horn showed various degrees of change. The number of cells was decreased, and of those remaining a few showed no pathological changes. In others there was complete chromatolysis with loss of granular material. Eccentricity of the nucleus was noted, but not to any great extent. Some of the cells were characterised by the deeply staining quality of their nucleoli. A marked feature was the lack of differentiation of the nucleolus and nucleus. The intranuclear network appeared homogeneous, staining uniformly with the cell protoplasm. These changes were present at all the levels examined.

The cells of Lockhart Clarke's column showed all degrees of change—e.g., eccentricity of nucleus and chromatolysis, but there was no apparent diminution in the number of the cells.

Cells of the Posterior Root Ganglia.—Normally in the spinal ganglion there are two types of cell: (1) large and faintly staining; (2) smaller and deeply staining. In the sections of the present case there seem to be a lack of internal differentiation of the substance in both types. The nucleolus could be distinguished with difficulty. The intranuclear network stained pink (stained with toluidin blue, counterstained eosin) or bluish, whereas the normal network shows little evidence of having taken up any stain. This change was more marked in some cells than in others. In some cases the nucleus was so swollen as to occupy the greater part of the cell, the cytoplasm being much shrunken. There seemed to be an excess of brown pigment in some of the cells (brown pigment was observed in the cells of the posterior root ganglia of a normal cord which was examined at the same time). These cells showed other degenerative changes—e.g., chromatolysis, vacuolation, and eccentricity of the nucleus. Neuronophagy was present but was not marked, and neither congestion nor hæmorrhage was noted.

Summary.—The chief changes found were in the nerve cells, both sensory and motor, and they were characterised by disintegration of the Nissl's bodies, pyknosis, shrinkage of the cell protoplasm, and eccentricity of nuclei. The presence of congestion and hæmorrhages was notable in the cord, but there was no round-celled infiltration or any change indicative of an inflammatory process.

Discussion.

The published accounts of the microscopical appearances of the cord in tetanus are conflicting. Some observers have found no changes or only congestion, whereas others have reported distinct lesions. Goldscheider and Flatau found an extreme diffuse chromatolysis of the ganglion cells and their observations were confirmed by Goebel. Westphal noted swelling of the nucleolus in a few cells in a single case.[1,2] In Hunter's series of three cases no changes were found in one case, while differences from the normal were found in the other two. Instead of triangular-shaped collections of deeper stained granules in the more faintly stained groundwork of the cells, the whole cytoplasm had a more or less uniform staining and showed none of this differentiation of its substance.[3] Charcot and Michaud described a subacute central myelitis and Bouchard a proliferation of neuroglia with pigmentation of the cells of the anterior horn. Rispal has described changes in the ganglion cells in his cases. Similar chromatolytic changes have been obtained in animal experiments.

There has been much controversy, also, respecting the significance of these lesions, whether they are to be assigned to the toxin or the tetanus bacillus or to the clinical manifestations of the toxæmia—e.g., convulsions which are believed to cause exhaustion of the ganglion cells, hyperpyrexia, &c.

The mode of diffusion of the toxin is also disputed. Marie and Morax, Meyer and Ransome [4] concluded from their work that the toxin passed up the axis-cylinders, which were reached from the motor end plates, and that maximal effects were obtained when the toxin was injected into a motor nerve and minimal effects when a sensory nerve was the site of injection. Teale and Embleton[5] concluded that the toxin also ascended to the central nervous system to a great extent by the way of the perineural lymphatics, and they found that the dorsal root ganglia had a definite filtering or blocking action for tetanus toxin.

In the case under discussion marked changes were found in the cells of the posterior root ganglia, in the cells of Lockhart Clarke's column, and in the cells of the anterior horn—namely, loss of differentiation of substance, chromatolysis, vacuolation, and eccentricity of nuclei. It is difficult to believe that this biochemical change is a sequel to the convulsions, since the sensory cells are affected as well as the motor cells and even more severely. While degenerative changes were observed in the ganglion cells throughout the cord, it is notable that the cells in the posterior root ganglion of the left fifth lumbar segment exhibited a perceptibly greater degree of degeneration than those of the other posterior root ganglia examined in the cervical and dorsal regions. This phenomenon admits of two explanations. On the one hand, the toxin might be transmitted by the nerve-fibres of the sensory root as well as by those of the motor root; or, on the other hand, diffusion of the toxin might proceed by the perineural lymphatics outwards from the cord, so as to injure the cells of the posterior root ganglion. In the latter case the maximal degree of injury in the posterior root ganglion of the fifth lumbar segment might be correlated with a maximal concentration of toxin at the level at which the toxin entered the cord.

These observations appear to warrant the deduction that the histological changes are attributable directly to the tetanus toxin and are not an expression of over-activity of the cells.

No evidence is available to indicate whether diffusion throughout the cord occurs by way of the lymphatic channels or by the axis-cylinders, but the initial symptom in the progress of the disease—viz., trismus, which is the result of the toxic process in the bulb, does prove that this diffusion proceeds rapidly.

I am indebted to Prof. John H. Teacher for the privilege of working under his supervision in the pathological department of the Infirmary, and to Mr. John Patrick for the opportunity of examining the spinal cord in this case and for the clinical history.

ROYAL MEDICAL BENEVOLENT FUND.—The following are some additional cases relieved at the last meeting:—

Three children of M.D. Edin. who practised in Yorkshire and died in 1916. Only income £15 per annum; uncles contribute £100 per annum. They live with a grandmother and an aunt. The Fund has helped with the maintenance to the extent of £93 during the last eight years and voted a further £18.

Daughter, aged 67, of M.R.C.S. who practised in London and died in 1885. Applicant is the eighth daughter of 11 children and supported herself up to 1919 when, owing to the war, her employers went out of business. Unable to obtain another post, now lives with a married sister and helps in the house, but the sister can ill afford to keep her. Relieved three times, total £54; now voted £26 in 12 instalments.

M.D. Edin., aged 72. Is bedridden and supported by his brothers, but they are unable to do more and the Fund was approached for a grant for pocket-money. In 1925 the Fund voted £17 and now a grant of £18 in 12 instalments has been made.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos-street, London, W. 1.

Clinical and Laboratory Notes.

MALIGNANT TUMOURS FOLLOWING ONE APPLICATION OF AN IRRITANT.

BY H. P. PICKERILL, C.B.E., M.D., CH.M. BIRM.,
SURGEON IN CHARGE OF THE FACIAL AND JAW DEPARTMENT, DUNEDIN HOSPITAL, NEW ZEALAND.

LAST year Dr. Marshall Findlay[1] recorded the results of some extremely interesting and apparently important experiments, demonstrating the experimental production of cancer by one application of tar. If these experiments are confirmed, as may be expected, they will have a most important bearing upon workmen's compensation cases. I was much struck by the fact that Dr. Findlay apparently could quote only two clinical cases where malignancy had resulted from the single application of an irritant. I feel sure there must be more. It is highly desirable that such cases should be published, and I therefore place on record the following three cases, which, during the last year, were referred to me for excision of facial growths and plastic restoration.

CASE 1.—A. B., man aged 45. Healthy, excellent physique. Showed a typical malignant ulcer of the lower lid of the left eye at the inner canthus. The history he gave, subsequently corroborated fully in the court and admitted as true by the judge, was that five months previously whilst at work on a dredge, a red-hot cinder burned him in the corner of his eye. The sore did not heal and gradually became larger. It was also established in the evidence that there was no lesion present in the eye before the burn. In March last year I removed the growth freely. The pathological report was as follows: "One edge of specimen shows masses of closely packed spindle-shaped cells in the subcutaneous tissue. Although there is a suggestion of cornification, the general structure is that of a rodent ulcer. It is a basal-celled carcinoma (rodent ulcer)."

The fact that there was cornification present raised some doubt as to whether it should not be classified as an epithelioma.

CASE 2.—C. D., man aged 43. Good health. Admitted complaining of a sore behind the right ear, which had been present for nearly two years and which had resulted from a burn from a lighted cigarette which he was carrying behind his ear. In September last year I removed half the ear and glands of the neck. The pathological report was as follows: "Tissue consists of masses and columns of squamous tumour cells, the masses showing central cornification. The stroma consists of loose fibro-cellular tissue heavily infiltrated with round cells. It is a squamous-celled carcinoma (epithelioma).

Obviously no compensation was involved in this case.

CASE 3.—E. F., man aged 65. Admitted in September last year. A large fungating growth of the upper lip about the size of a hen's egg. Patient gave a definite history that 15 years ago he was burned on his lip by a very hot pipe. The pipe (tobacco) had been resting on the side of a furnace when he took it up. Patient stated that the burn took a very long time to heal and there was always a lump on the inner surface of his lip, which started getting larger rapidly about six months ago. The lip and glands of neck were removed and the following pathological report was received: "The section of a piece of tissue from lip shows a papillomatous type of growth with much more surface cornification than downgrowth. The glands of right and left sides show no evidence of malignancy. It is a slowly growing malignancy supervening on a squamous papilloma of lip."

In Case 1, referred to above, the patient was unsuccessful in obtaining any compensation because at that time, here, we were unable to produce any evidence of malignancy having resulted from the application of a single irritant. I should imagine that were the case to be tried again now, the patient might be more successful.

It is interesting and perhaps significant to note that in each of these three cases there is a definite history of a burn, and that Dr. Findlay produced his cancers in mice by the single application of *hot* tar.

A CASE OF SURGICAL EMPHYSEMA IN SCARLET FEVER.

BY F. R. CURTIS, M.Sc., M.B., CH.B. LEEDS,
RESEARCH ASSISTANT IN PHYSIOLOGY, MIDDLESEX HOSPITAL MEDICAL SCHOOL;
AND
I. C. THOMSON, M.B., CH.B. ST. AND.,
ASSISTANT MEDICAL OFFICER, MANCHESTER FEVER HOSPITAL.

CASES of non-bacterial subcutaneous emphysema do not make a large chapter in medical literature. In 1919 Alexander and Follett[1] published a very complete survey of the condition with clinical instances. They mentioned cases due to trauma of the air-passages, nasal and frontal sinuses, &c., and later, in 1922, Rosenheim[2] recorded a case of traumatic surgical emphysema after tonsillectomy. But so far as we can find there seems to be no record of emphysema occurring during scarlatina.

The patient, a girl aged 6 years, was admitted on Dec. 10th, 1925, with a well-developed punctate erythema on the trunk and limbs. The tongue showed partial peeling, and the papillæ were prominent. The fauces were injected, the tonsils slightly enlarged and slimy, but no exudate was present. The cervical glands on both sides were somewhat enlarged. On the 11th the rash showed considerable blotchiness and staining. As the child's general condition was worse 20 c.cm. of antiscarlatinal serum were given. The tonsils and fauces now showed great ulceration and the cervical glands were larger, but no fluctuation could be detected. On the 12th to the 20th the child improved steadily in general health, though there was still considerable ulceration of the tonsils and enlargement of the cervical glands, especially at the left angle of the jaw. On the 21st, during routine examination, well-marked surgical emphysema was found, extending from the left mastoid process down the side of the neck on to the chest in front and behind, and spreading round the root of the neck to involve the right clavicular region. At this stage the throat showed marked erosive ulceration of the left tonsil spreading backwards on to the lateral pharyngeal wall. Sloughs were present in the pharynx, but no perforation was visible. Later the emphysema had extended to the left wrist and down the right side of the neck and chest. By midnight it was present over the whole trunk, being limited below by the iliac crests and Poupart's ligaments and above by the lower jaw, the mastoid processes, and superior curved occipital lines. On the 22nd both arms were involved as far as the wrists. Spread was taking place over the sacrum, but not over Poupart's ligament. There were no abnormal signs present in the chest, nor were there any alterations in the character of the respiration. A needle was inserted in the left infraclavicular region and much air escaped. In order to expel all the air, an incision was made under novocain, just in front of the left sterno-mastoid muscle at the level of the cricoid cartilage. The incision was deepened until air rushed out. The child was then bandaged tightly from below upwards. The wound was left open, protected only by a slight layer of sterile gauze as in tracheotomy cases. The child's general condition, which at first was fairly good, gradually became worse and death took place on the 24th.

Post-mortem Examination.—A dissection of the neck showed emphysema behind the platysma and superficial cervical fascia. The upper cervical glands were enlarged; one on the left side was breaking down. On the left side, too, there was a small collection of pus behind and below the posterior belly of the digastric, and passing behind the carotid sheath. The pus led to another small collection between the palatopharyngeus and the wall of the pharynx. In this situation, on a level with the junction of the tongue and epiglottis, was a small punched-out perforation one-tenth of an inch in diameter, lying in the centre of an ulcer behind the posterior faucial fold. No affection of the larynx was found. Unfortunately the pus was not examined, though clinically there was never any suggestion of gas-gangrene.

We are indebted to Dr. R. Veitch Clark, medical officer of health for Manchester, for permission to publish this case, which occurred at the Manchester Fever Hospital, Newton Heath.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

THE MANCHESTER SCHOOL.

A MEETING of this Section was held on Oct. 15th, when Prof. A. DONALD delivered his presidential address, giving a Historical Survey of Obstetrics and Gynæcology in Manchester. St. Mary's Hospital, he said, was founded 136 years ago by Charles White, the author of a treatise which had revolutionised the treatment of puerperal fever. Other great names connected with the hospital were Charles Clay, a pioneer surgeon, the first to perform abdominal hysterectomy for fibroids; Charles Cullingworth, a great diagnostician who dispensed with the uterine sound; and William Sinclair, founder of the *Journal of Obstetrics and Gynæcology*. The teaching of the Manchester school had a certain individuality. It early supported the treatment of prolapse by a vaginal plastic operation. It believed in curettage for disturbed uterine function as manifested by disabling dysmenorrhœa, profuse leucorrhœa, &c. It regarded retroversion as the first stage of prolapse, treating it by vaginal operation and performing suspensory operations only when there was much pain, with enlargement, or sterility. It also made a practice of removing both ovaries in hysterectomy, as the result of experience and of statistical inquiry into the results of complete and partial operations.

Dr. WATTS EDEN proposed, and Dr. RUSSELL ANDREWS seconded, a vote of thanks to the President for his address.

Mr. VICTOR BONNEY read a paper on the outcome of 214 radical abdominal operations for

Carcinoma of the Cervix.

The operations in this series, he said, were performed between April, 1907, and October, 1921, and all had been followed up by letters or interviews. The removal had always been as drastic and radical as was compatible with recovery; the glands in the obturator fossæ and along the iliac veins were always taken away, and practically all the vagina. In most cases spinal and full ether anæsthesia was used. Many of these patients had been dismissed from hospitals as inoperable. The only contra-indications recognised were deep and extensive involvement of bladder, bowel, or both ureters. The only reliable grouping of cases was according to whether the regional lymphatic glands were or were not carcinomatous at the time of operation. Of the 214 patients, 121 had healthy glands and 93 had carcinomatous glands. The operability rate at the Middlesex and Chelsea Hospitals worked out at 63 per cent. up to 1910; this figure was retained in subsequent publications because after 1910 it was no longer possible to estimate the rate accurately. Probably in recent years it was more nearly 70 per cent.

Results.

The figures were :—

—	Five years later.	Seven years later.	Ten years later.
Died from—			
Operation ..	34 (15·8 %)	32	25
Recurrence ..	82 (62 %)	69	45
Other diseases ..	5	5	4
Lost sight of ..	8	20	20
Free from recurrence	85 (40 %)	56	36

Early recurrences usually took place in the pelvic cellular tissue, rectum, or bladder, or the upper end of the vagina if this had been left behind. Later recurrences were generally found in the tissue along the side wall of the pelvis and along the vessels or in the pelvic bones or vertebræ. Taking the operability rate as 63 per cent., then the 85 "five-year cures" represented a recovery rate of 25 per cent.—certainly an underestimate. Where the glands were carcinomatous the operative death-rate was 21 per cent., and the recurrences rose to 61 per cent. and occurred sooner. Nevertheless, it was encouraging to find that 23 patients with gland involvement remained healthy for five years at least. Five years had proved to be too short a time on which to claim a cure, and even seven years was not wholly sufficient, although it covered the vast proportion of recurrences, five of which became manifest between the sixth and seventh years. A "seven-year cure" was found to have been effected in 30 per cent., but this underestimated the successes, because 20 had by then been lost sight of. Where glands were carcinomatous only 29 per cent. remained well seven years after; but this implied that 17 individuals were well out of 76.

After Ten Years.—One hundred and thirty operations could be reviewed after a ten years' interval and showed an operative mortality of 19 per cent. and over 34 per cent. of "cures" among the survivors; 30 per cent. of these had had carcinomatous glands. Finally, a review of the whole series to-day brought out several new points: 57 patients were free from recurrence up to 18½ years, 32 of them having survived their operation ten years or more. The total number of known deaths from recurrence was 90—i.e., one-half of the number of those who recovered from the operation. The table was complicated by cases lost sight of, but an estimate of the chances of recurrence among these brought the number of "ten-year cures" up to 51. Thus slightly less than 50 per cent. of the patients who survived operation might be claimed as absolute cures. The chance of recurrence and cure in cases with carcinomatous glands was as two to one, and of those without gland involvement as two to three. The results of the radical operation might be calculated as follows :—

	Advanced group.	Moderately early group.
Operative deaths ..	20	10
Recurrences	54	36
Ten-year cures ..	26	54

The two groups could be further subdivided according to the degree of advancement, but the classes could not be distinguished clinically with any certainty. In reaching a prognosis every point had to be considered—e.g., age, physique, state of health, duration of pain and of bladder symptoms, motility of the cervix, involvement of vaginal wall and its situation if present, and duration of bleeding. The most reliable guides—where all might be fallacious—were pain, bleeding, and bladder symptoms. A useful rule was: three months' bleeding, growth certainly removable; six months' bleeding, possibly removable; 12 months' bleeding, most probably not removable.

Discussion.

Mr. CUTHBERT LOCKYER said he thought gynæcologists might become a little too optimistic if they based their conclusions on the statistics of an exceptional operator like Mr. Bonney alone. The good results of treatment by X rays and radium must also be taken into account and there was room for both. He himself would never do a Wertheim for advanced cases, since he believed better results were obtained by radium. He quoted the figures of American and Viennese workers, which he found very impressive. Moreover, the palliative results of radium and X rays had to be taken into account, the freedom from hæmorrhage, pain, and discharge which they ensured. He quoted a case of recurrence in the vault 15 years after operation.

Prof. FLETCHER SHAW recalled the early days of the Wertheim operation in this country and emphasised the debt of British gynæcology to Mr. Bonney and

Mr. Comyns Berkeley, who published their first series of results at a time when others were getting disheartened and might well have given up the method altogether. He himself had operated on 141 cases with a death-rate of 24 per cent. His operability rate was 57 per cent., but he did not regard this as a statistic of great significance; he operated on every case in which there was any chance of removing the growth because he believed the operation to be the one measure giving a chance of permanent cure. Pain was an important consideration; if there was pain the growth was usually irremovable. A very serious trouble was fat, and it seemed to be the fattest and healthiest-looking women who got carcinoma of the cervix. A very common cause of death was urinary infection, although shock accounted for the greatest number. He had found that almost all the recurrences took place in the first two years. Of his 42 cases with recurrence 21 occurred in the first year, 13 in the second, three in the third, one in the fourth, two in the fifth, one in the sixth, and one in the ninth year. If at the end of a year the patient was healthy, felt well, and had a good colour the chances were that she would do well. If she was flagging somewhat, without obvious recurrence, it was probable that she would develop a further growth during the ensuing 12 months. After five years he could trace 70 out of 75 patients who had survived operation; 15 (20 per cent.) had died and 28 (37·3 per cent.) had recurrences; two had died from other causes, one of tuberculous meningitis; 25 were alive and well (33·3 per cent.). After seven years 16 out of 50 were well (32 per cent.). The good results claimed for radium treatment were all from abroad and English figures came nowhere near them. Clinically, he had concluded that radium was not of much value, but on working out his statistics he found that 41 per cent. of those who were treated with radium before operation were alive and well, against 32 per cent. of those who had not had radium. He thought it was of great importance that workers should publish their figures for discussion.

Mr. L. C. RIVETT said that he had done 40 Wertheim operations in the last seven years; ten of the patients had died from the operation and three from urinary infection developed 10 to 12 weeks after leaving hospital apparently well. This infection was a very troublesome complication and did not seem to have any reference to bladder involvement by the growth. He agreed with Mr. Bonney's points for determining operability and that examination was most deceptive. If the growth was not removable he tied the internal iliacs, ovarian and uterine arteries and had often been surprised at the improvement following this measure. He thought that radium acted by producing a fibrosis which cut off the blood-supply, but the difficulty was to make the radium act on all parts of the growth.

Dr. RUSSELL ANDREWS said that few people did such an extensive operation on such difficult cases as Mr. Bonney or could equal his results. Prognosis was extremely difficult in any given case and he had often felt after operating that he had made a mistake, and yet found the patient alive and well five years later. Out of his first 100 he knew that 24 were well after seven years; most of them had been old or elderly when the disease arose. The most adverse symptom was long-continued pain. The cauliflower growth, not often seen nowadays, might lead to long-continued bleeding with little invasion of the cervix and so give an unexpectedly good result.

Mr. BONNEY, in reply, said that he did not agree that the success of the operation depended on dexterity; it was a matter of learning to do it properly—a full hysterectomy was no good at all. Workers who did not perform the extirpation completely might blame the method for their bad results. He could not make head or tail out of the foreign radium figures and preferred to disregard them until British figures were published in corroboration. The only definite standard of operability was to go for every case in which there was the slightest possibility of getting the growth out. He knew no way of preventing the urinary infection. Logically, if radium were to be used at all it should be on the early cases, since the late ones usually had glandular involvement. He had not cited pain as an important factor in determining the operability because in nine cases out of ten it meant that the growth had extended beyond the cervix and so was inoperable.

Prof. LOUISE MCILROY presented two short communications.

1. *Malignant Disease of Both Ovaries in a Girl of 18.*—The patient had had a severe attack of abdominal pain radiating from the right iliac fossa over the abdomen and had been getting thinner. On admission free fluid and two movable tumours were found, and the uterus was fixed. On operation the whole pelvic peritoneum was found densely studded with nodules which bled readily, and there was a tumour of each ovary; the appearance was characteristic of carcinoma. The tumours and all the ovarian tissue were removed: the patient recovered and had been seen several times since. She continued in good condition and menstruated regularly. The pelvis was still slightly tender, and the nodules in the peritoneum and some swelling around the uterus were still present. Pathologically, the tumours showed ambiguous characteristics, being probably a borderline growth between carcinoma and sarcoma.

2. *Endometrioma of the Ovary.*—The patient was a spinster aged 36, who complained of violent attacks of pain and sickness, which, she maintained, had no relation to the menstrual period. The right ovary was found on operation to be the size of a tangerine, cystic, and adherent. The left ovary and the tubes were healthy but congested. The right ovary was removed and the patient made a good recovery. The sections showed typical endometrial glandular tissue with no great invasion of the ovarian stroma.

The PRESIDENT referred to a patient with a similar apparently malignant growth who made a good recovery.

SECTION OF THERAPEUTICS AND PHARMACOLOGY.

AT a meeting of this Section held on Oct. 12th, Dr. GEORGE GRAHAM delivered his presidential address on the

TREATMENT OF GOUT.

He said that he had chosen this subject because there was an impression, often based on faulty diagnosis, that gout had become rare, because there had been great improvement in the treatment by drugs and because unpleasant symptoms sometimes followed the exhibition of cinchophen.

In *diagnosis* the presence of typical gouty attacks in other members of the family was a very valuable indication, as was also the history of the first attack, which was often typical although later ones were not. Gouty joints were nearly always asymmetrical, which dintinguished them from subacute infective arthritis. Tophi were helpful but inconstant. Since sodium biurate was deposited in the bones and was not opaque to X rays the skiagram in long-standing cases showed obvious clear areas, best seen in the small bones of the extremities. Identical changes were found in lupus pernio and similar ones in association with psoriasis. In old subacute infective arthritis there was a general loss of calcium, so that the shadow was not good, but there were no punched-out areas in it. The estimation of the uric acid in the blood might be a great help. It was raised in chronic nephritis with urea retention and in leukæmia, and might be high in people who had never had gout. Moreover, some patients with typical gout had no increase in blood uric acid, but on the whole a joint lesion combined with raised uric acid was probably gout. The uric acid content had been observed by Gudzent and Folin to increase when an attack was impending.

In *treatment of the acute attack* the first essential was rest for the affected limb, however slight the pain. Local applications such as lotio plumbi gave relief.

The best drug was colchicum taken in large doses as soon as the attack began (vinum ℥ xv.–xx. every four or eight hours, or colchicine 1/100–1/32 gr.). The mode of action of colchicum was not yet understood and it would not prevent attacks. Unpleasant symptoms resulting from its use varied from pain after meals, malaise, and headache to severe dyspepsia and diarrhœa. The cinchophen group was also of value.

In *prevention of the attack* diet played a great part. All foods containing much nucleo-protein must be avoided—gland-organs, beef, &c. The total protein must not exceed 60–80 g. daily (10–12 g. nitrogen). Sugar, tea, and coffee used to be forbidden, but were now usually permitted. Alcohol undoubtedly played some part in causing gout, and Widal and others had found that gouty patients often gave skin reactions to certain wines, especially red Burgundy. Port did not give skin reactions, although in this country it was considered, together with beer and champagne, to be a potent exciter of gout. General health must be maintained and all sources of sepsis removed. The most valuable preventive drug was cinchophen, a derivative of quinoline, sold under various proprietary names (atophan, agotan, phenoquin, quinophan). This caused a great increase in the output of uric acid, even in healthy persons; some thought it did this by increasing the purin metabolism, others by stimulating the kidney. Experiments showed that the uric acid began to reaccumulate in the blood as soon as the drug was stopped, although the output continued good. There was no evidence for increased formation, so the accumulation was probably derived from the sodium biurate deposited in the tissues. The experiments of Folin and of the speaker seemed to show that the extra uric acid excreted came first from the blood and tissues and then from the biurate stores in the body. Whatever the opinion held on the relationship of uric acid to gout, these stores could not be good for the patient. Another observation showed that cinchophen only caused an increase in output for the first two or three days, so that the best régime of administration was three-day periods with intervals. Most patients treated in this way had no more acute attacks, and their local condition improved immensely. Sodium salicylate and sodium benzoate also caused an increase in the excretion of uric acid, but 100 gr. a day of sodium salicylate produced noticeable effects on the patient, whereas cinchophen usually did not. Cinchophen also relieved the pain of acute rheumatism and infective arthritis, and its effect on the liver made it useful in catarrhal jaundice and icterus neonatorum. Its action in causing an increase in the volume of the bile, in the total dry solids, and in the pigment matter was only approached by that of desoxycholic acid.

Death following Cinchophen.—Several deaths had been recently reported from jaundice following a course of cinchophen. Investigation showed that the preparation and dosage had varied, but that in every case the drug had been given without intermissions. In some instances early signs of disturbance passed unnoticed. The speaker had tested the uric acid in the blood, the blood-sugar, and the liver function (lævulose test) in three patients who had been taking large quantities of cinchophen for some time, and proposed to examine its effects on normal people. One of his patients showed some sign of liver damage, and appeared to be taking more cinchophen than she really needed; the dose was, therefore, reduced to 15 gr. a day for two consecutive days in each week. He would be loth to give up the drug, since it gave such excellent results, but recommended that it be used mainly for gout, that it should never be given for more than four days without an intermission of at least four days, and that the blood uric acid should be estimated at intervals of six months and the dose reduced if the test showed a normal quantity. Possibly, also, a guide to delayed excretion might be given by testing the urine, which gave a green colour with weak hydrochloric acid in the presence of cinchophen.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

HEALTH ADMINISTRATION.

IN his presidential address delivered to the Society on Oct. 15th Dr. E. H. SNELL, medical officer of health for the city of Coventry, sketched the growth of health administration in this country, some of its anomalies and some of its obvious deficiencies. Health administration, he said, generally lagged behind preventive medicine, and was dependent, of course, on many other factors than those introduced by administrative officers. The Local Government Board, even when it became the department of Government concerned with the administration of the Public Health Act, found that its powers were of a limited character; it could only bring indirect pressure on a local authority that was slow in following its advice. One of the Board's most powerful levers, however, for moving local authorities, was by means of reports of inspectors. On the occurrence of an outbreak of illness or for various other excuses, an inspector was sent to the district to report on its sanitary administration; it was always a comparatively easy matter (especially with that wisdom which comes after an event) for an inspector to write a report reflecting on the negligence of the local council or its officers, or both. These reports were printed, and being of local interest found a good press in the local papers. It must be admitted that this system of reports worked well, though its effects were necessarily sporadic and often slow.

The latter part of Dr. Snell's address was devoted to the scope of health administration and the use of health propaganda.

Scope of Health Administration.

In the early days of the last half century, said Dr. Snell, efforts were directed mainly to the removal of gross nuisances causing noxious effluvia; the working of the Public Health Act specified the kind of nuisance a local authority could deal with, and its meaning had since been stretched to cover many conditions not originally contemplated by its promoters. The officer to carry out these duties was dubbed "inspector of nuisances," a name long since replaced by the title of "sanitary inspector." A healthy environment was sought by obtaining the proper removal of sewage, disposal of refuse, pure water-supply, healthy housing conditions, and so forth. It was possible to cleanse compulsorily a verminous house, but not the verminous person who infected the house. An early infringement of personal liberty in health matters was the penalty on exposing an infectious person in a public place and his compulsory removal to hospital. The local authority thus became responsible for his treatment. The Public Health Act gave local authorities power to build and maintain hospitals for the sick poor of their district on obtaining the sanction of the Local Government Board. The power was not limited to fever hospitals, but in practice sanction was not sought to construct any others, though for many years there had been a small municipal hospital for accidents at Barry, and more recently the Poor-law infirmary at Bradford had been converted into a municipal hospital.

In the course of time the close association of the cure of disease with its prevention became appreciated. The medical inspection of school-children was made compulsory 18 years ago, and it was inevitable that this should be followed by provision for treatment. The commonest ailments of children were provided for, and now in most areas some provision existed for dealing with eye and throat defects, dental disease, and certain skin diseases. Then certain of the more progressive of the local authorities started providing sanatorium beds for tuberculosis; a great fillip to this movement was given by the passing of the National Health Insurance Act of 1911, and sub-

sequently it became the duty of counties and county boroughs to make this provision both for insured and uninsured. Since then the *duty* has been imposed on these bodies to draw up schemes for the free treatment of venereal diseases. And the Maternity and Child Welfare Act of 1918 gave the *power* to these bodies to make provision for caring for the health and welfare of nursing and expectant mothers, and children below school age. It was curious to note that nothing in this Act was compulsory beyond the duty of forming a maternity and child welfare committee; that committee once formed need never meet, yet the Act would have been complied with. In practice, however, many if not most, authorities had already done much in this direction by the appointment of health visitors.

The cure and prevention of illness was so intimately related that, said Dr. Snell, it seemed inevitable that in the future the ordinary medical curriculum would have to cover both. State services relating to both were represented in the Ministry of Health. And even the method of payment of the insurance practitioner was such that the more successful he was in averting illness from his patients the less work he had to do. Much good work was possible from the practising medical profession if they would cultivate the spirit both of curative and preventive medicine. Curative medicine made a strong appeal to the charitable. Sympathy with the sufferer was natural. But this had the effect of making sanatoriums and hospitals the shop windows of public health, whereas they were merely the backwaters.

Health Propaganda.

It could not be said that nothing has hitherto been done by health authorities in regard to propaganda; but now, for the first time, this form of activity became statutorily one of the powers of local authorities. "It behoves us," said Dr. Snell, "as the responsible medical advisers of local authorities, to endeavour to see that such powers are used with due circumspection. The object in view is the prevention of illness. This can probably be best obtained by the avoidance of sensationalism, fads, and stunts. Let *our* advice be sound and founded on proved facts, or let it be nothing at all. We now know that the same methods of prevention cannot be applied to all diseases that can be classified as infectious. Isolation and disinfection were once regarded as the panacea for all infectious diseases. And probably most of us are familiar with circulars containing advice as to how to avoid this, that, or the other disease, the only value of which has been to the printer who printed them. It may appear harmless to advise good food, exercise, open air, and sanitary houses as assisting the combating of infection. But it is not altogether true. We now know that those children living under the least sanitary conditions are the least prone to contract diphtheria. Also such advice is founded on guesswork rather than on any evidence of its truth. The last published annual report of the Chief Medical Officer of the Ministry of Health casts doubt on its value in the case of influenza. After giving particulars concerning an outbreak of influenza in a school, it concludes by saying, 'The report is interesting as an illustration of our helplessness in controlling the spread of influenza, even in school, where the boys are given every care and attention, and where they live in what appear to be ideal hygienic conditions.'

"Take the case of encephalitis lethargica. Now that its signs, symptoms, and sequelæ are becoming recognised better, this disease looms largely on our horizon of fatal and malevolent maladies. But of its prevention we know practically nothing. A circular regarding its prevention would be as useful as one on the avoidance of thunderbolts. We have reason to believe that the regular evacuation of the contents of the large intestine is of enormous and even incalculable advantage to the individual. Let us say so. But it is not necessary for us to assert that cancer will be hereby avoided, or to endeavour to prescribe a diet which will eliminate all risks of this fatal malady. Such statements—for which there is not one iota of evidence—we can well leave to those voluntary societies who are willing to make them. I desire to draw a dividing line between responsibility and irresponsibility. We now have some definite and positive information regarding the obtaining of immunity to diphtheria and possibly also to scarlet fever. We have had even *more* positive evidence regarding the prevention of small-pox for over 100 years. We cannot claim any marked success regarding the propaganda work undertaken in that behalf. We have to recognise that there is an antagonism to propaganda work both passive and active. It is easy to arrange lectures; it is difficult to provide audiences. Even wireless broadcasting has its limits; educative lectures are turned off as relentlessly as most of us turn off jazz music."

Dr. Snell concluded with the regretful admission that our knowledge of preventive medicine is not sufficiently reflected and utilised in our administrative procedures. This was largely due to the want of exact knowledge among legislators, and the fact that political expediency was too often allowed to govern legislative enactments.

HUNTERIAN SOCIETY.

A MEETING of this Society was held on Oct. 18th, when Mr. MORTIMER WOOLF delivered his presidential address on

PAIN.

Although, he said, the fear of pain was often a deterrent, pain itself was the predominant symptom for which the majority of patients sought medical advice. Since the work of Hilton discussion had centred on the site of origin of pain, especially in the abdomen, the question being: Is visceral pain felt locally, or on the parietes of the body remote from its origin, or both? Mr. Wilfred Trotter considered that the pain nerves were those which ended or commenced in the tissues by means of nerve-fibres deprived of their neurilemma—i.e., that the ends of the nerves were uninsulated; he thought that arborisation of these uninsulated nerve-fibres formed an end-organ for the pain nerve. That a nerve termination of this nature was capable of producing pain could not be gainsaid; but, though pain could be produced by an uninsulated nerve-fibre, it need not follow that this was the only mechanism for the production of painful sensations; a blow on the ulnar nerve gave a very definite sensation of pain in the distribution of that nerve, although the area of the nerve stimulated was well insulated. These so-called "end-organs" for pain seemed to be in an entirely different category from those existing in connexion with the ordinary sensations such as touch, sight, and hearing. The paths of deep sensibility and localisation had been well worked out, but pain was different. It seemed almost universally connected with all sensations, and the President thought that it was nothing more nor less than a hyper-stimulation of a normal and specific sensation. Pinprick, heat, and light might all elicit pain if the stimulus was increased.

To the surgeon, he continued, there was one sensation of particular interest—namely, the sensation produced by the physiological contraction of muscles. The body was dependent on the tension of the muscles for a sense of the position of joints, and if this tension was excessive or abnormal, pain was produced owing to the hyperstimulation of a normal sensation. This seemed to be the explanation of Sir James Mackenzie's view that in acute abdominal disease the muscular layer was usually more hyperalgesic than the cutaneous tissues. In the viscero-motor reflex, where the abdominal muscles were held tense in order to protect an underlying diseased focus, it was, he thought, the tension of the muscles that made them painful. Pain after abdominal operation was largely muscular in origin, and, to a large degree, was situated

in the abdominal wall itself. The pro-peritoneal layer of fat was probably very sensitive, and to some extent this accounted for post-operative pain; but the muscular layer was the chief culprit. If this was true it was wise, if possible, not to sever or split the muscles but to draw them aside. If sutures were put into the aponeurotic sheaths rather than the muscles themselves, the patient seemed to suffer less pain.

The definition of pain as a hyperstimulation of normal sensation, continued the President, applied also to involuntary muscles. At the present time one school of thought believed that all abdominal pain was referred and could not be felt nor even produced in situ. Another school held that there was one form of abdominal pain produced and felt in situ, and caused by intravisceral changes of tension. Sensations were only present when they were of physiological use, and pain, heat, and cold all had a definite purposive physiology, whilst muscles conveyed the sensation of localisation. In hollow viscera there was no necessity for the sensations of heat, cold, touch, or, with very few exceptions, localisation; but there was a very real need that the intestines should be constantly kept informed of their state of tension. The purposive physiological sensation of the alimentary tract was the state of tension of its involuntary muscle, and when, for any reason, this became abnormal pain was produced locally, and, he believed, not uncommonly felt locally. It had been said that abdominal pain was due to tension on the mesentery, and that when the intestine dilated the mesenteries were pulled on, the nerves in them stimulated, and pain produced. The President very much doubted whether this was true. In colostomy the meso-sigmoid was stretched but the operation was not painful. The pain caused by sequestration of a part of the gut was probably caused by the secretion of gas, which over-stimulated the involuntary muscle surrounding it. This kind of pain, due to alteration of tension—e.g., in hernia or appendicitis—could often be localised fairly accurately, the patient placing his finger at the site of the lesion. On two occasions the President had been able to alter the intra-intestinal tension by inserting a plug, and on each occasion produced pain.

In conclusion, the President said that he believed that there was a form of abdominal pain produced and felt locally, and that abdominal pain could be produced by, at all events, one mechanism which made it comparable to pain elsewhere in the body—namely, by hyper-stimulation of a normal and specific sensation.

Discussion.

Dr. D. A. COLES inquired what was the most reliable sign of pain and how it was to be measured.

Dr. CAMPBELL MCCLURE pointed out that if an elastic bag in the rectum was rapidly inflated it caused pain referred to the sacral area and over the pubes. He thought that the facts did not support the idea that pain was an exaggeration of normal sensation.

Dr. J. A. RYLE considered that there was something in the view that pain represented an exaggeration of normal sensation, although this was contested by neurologists. It was a familiar experience that every grade of sensation existed in the stomach and bladder, for example. He believed that an increase in the tension of muscle-fibre—especially when rapid—or simply its failure to relax, was the cause of pain in a viscus. Distension, however, might exist without any pain, whilst the most severe biliary colic occurred without distension of the gall-bladder. He thought that the same argument applied to arterial pain—e.g., intermittent claudication—for which, he said, angina cruris would be a better name since the condition was analogous to angina pectoris and abdominis. From some cause—such as arterial disease, toxins, tobacco, or nervous unrest—the artery was unable to relax to adapt its posture. The mechanism was the same in all cases—an increase in visceral pressure with inability to relax. General practitioners, said Dr. Ryle, had a great opportunity for registering a series of observations on pain, and these would be of great diagnostic and practical importance. Such work could not be done in the laboratory or with animals. He believed that referred pains depended upon inflammatory changes, a different stimulus to that which caused visceral pain. The referred pains—e.g., those due to irritation of nerve-endings in a damaged organ—might persist for days after a visceral pain had subsided. It was important to observe also the gesture which accompanied visceral pain and which often localised it with great accuracy.

Dr. F. G. CROOKSHANK supported the theory that pain was an exaggeration of a normal stimulus. He said that dissociation of gas from the capillaries in the wall of a viscus certainly caused a visceral distension and was analogous to what happened in the swim-bladder of fishes.

Dr. E. P. POULTON cited the cornea, in which, he said, pain was the only sensation and was conveyed by uninsulated fibres. The pain of gastric ulcer was not located in the ulcer but in the viscus. He thought that burning pain signified that muscles were continuously on the stretch; the pain of angina was due partly to stretching of the heart muscle.

Dr. DAVID BARCROFT threw doubt on the existence of pain in many cases. It often persisted long after its cause had gone away.

Dr. HOWARD HUMPHRIS said that he had believed for many years that pain was due to pressure and that the best treatment was the relief of that pressure.

Dr. BRANSBY YULE said that he had often found that œsophageal pain was localised to the lesion. Muscle was often in a state of contraction; it was hypertetanic contraction that meant pain.

Dr. H. A. ELLIS said that he believed that pain was the overflow of central disturbance caused by local irritation.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Oct. 7th, when the President, Dr. E. RIVAZ HUNT, gave his presidential address on

Cholecystitis.

Dr. Hunt said that, according to Dr. Arthur Hurst, cholecystitis is the most common of all chronic abdominal disorders, probably occurring in at least 20 per cent. of all persons. It is probable that if practitioners were more definitely on the look-out for this condition many attacks of biliousness, indigestion, flatulence, or even of that much-abused term "influenza," could be attributed to cholecystitis. Gall-stones, which are found post mortem in at least 10 per cent. of all persons dying after the age of 20, are probably nearly always secondary to cholecystitis which may have resolved long before. He emphasised the importance of recognising this disease as a focus of chronic sepsis.

Dr. Hunt reviewed briefly the anatomy and physiology and pathology of the gall-bladder, and then described the symptomatology of cholecystitis. The onset was usually gradual, and as a rule there was little if any pyrexia, except at intervals when short attacks of a characteristic type might occur. Flatulent dyspepsia was the most prominent symptom, usually coming on immediately after meals, though when associated with reflex hyperchlorhydria it simulated the hunger-pain of duodenal ulcer, beginning two or more hours after a meal, and being then relieved by food, alkalis, or vomiting. Vomiting was uncommon, but nausea frequently present, and often some irregularity of the bowels. Jaundice was not a marked feature. The pain of cholecystitis was not infrequently a recurrent gastric pain, often worse at night; owing

to the close association of the centres in the spinal cord innervating the stomach, liver, and gall-bladder, the irritable focus in the cord might not be necessarily due to a gastric lesion, but might arise from disease of a neighbouring organ. Viscerosensory accompaniments of cholecystitis included superficial and deep soreness in the right upper gradient of the abdomen, right subscapular and interscapular pains, and tenderness over the middle dorsal spines and along the course of the eleventh right rib. In some cases of cholecystitis in which the gall-bladder was situated abnormally high up the inflammation of the gall-bladder might extend to the under surface of the diaphragm, giving rise to many of the signs and symptoms of subphrenic abscess, and might even masquerade as a pulmonary affection with slight dullness at the base of the right lung, râles, and slight pyrexia.

Dr. Hunt described various methods of demonstrating gall-bladder tenderness, and considered the differential diagnosis of an enlarged gall-bladder. He emphasised the importance of remembering that such newer methods should be considered as accessory only and not as short-cuts to diagnosis to the exclusion of the older and simpler methods. The treatment of acute cholecystitis was surgical. The treatment of chronic cholecystitis might be broadly divided into two classes: (1) Cases in which secondary complications, such as gall-stones or evidence of secondary septic troubles elsewhere are present. For these operation is the ideal course. (2) Cases in which secondary complications are absent or in which operation is declined or for some other reason is inadvisable. For these medical treatment may be first tried. An important point was the removal of any primary focus from which infection may be conveyed to the gall-bladder. Oral sepsis, tonsillitis, infection of the accessory nasal sinuses, chronic appendicitis, pelvic infections in women, and *Bacillus coli* infections must be looked for and treated. An attempt must be made to treat the gall-bladder infection by means of biliary antiseptics and provision of adequate drainage. Large doses of urotropine, combined with alkalis, given in the manner advocated by Dr. Hurst, may be used, or the same drug, combined with cholic acid, as in felamine tablets, is sometimes efficacious. Salicylates or aspirin in large and regular doses have been advocated. Magnesium sulphate in concentrated solution by the mouth promotes biliary drainage.

Dr. Hunt insisted on the importance of exercise, especially horse-riding and rowing. The diet should be carefully supervised so as to avoid or restrict those articles of food which contain or produce cholesterol.

Dr. Hunt concluded his paper by giving a brief description of cases illustrating points referred to.

DONCASTER INFIRMARY.—The Prince of Wales, on Oct. 12th, visited Doncaster primarily for the purpose of laying the foundation-stone of the new wards at the Royal Infirmary, which will be associated with the memory of Queen Alexandra. Since the infirmary was founded in 1868 the population has risen from 18,000 to 200,000. The number of beds in the new building will eventually be 600, and of the £110,000 immediately required for the new wards £48,000 has already been subscribed. It is hoped that much of the remaining sum needed will be contributed by the Miners' Association when work in the pits is resumed.

DONATIONS AND BEQUESTS.—Mr. Frederick Lewis Brandon Siddons, of Hanger Hill, near Ealing, and formerly of Calcutta, besides other bequests left £700 each to King Edward VII. Hospital, Ealing, St. Dunstan's Hostel for the Blind, the Hospital for Sick Children, Great Ormond-street; to Bedford Grammar School for the benefit of the school, and £700 for the upkeep of the panel in the school chapel in memory of his three sons.—King Edward's Hospital Fund for London has received a gift of £10,000 sent by Mr. Albert W. Searle.—Under the will of the late Mr. A. B. Bosher, of Tunbridge Wells, some £265,000 will be divided between the Lord Mayor and Corporation of London and the Mayor and Corporation of Sheffield for allocation to hospital charities within their respective areas.

Reviews and Notices of Books.

EVOLUTION.

Nomogenesis or Evolution determined by Law. By LEO S. BERG, Chief of the Bureau of Applied Ichthyology, and Professor of Geography in the University of Leningrad. With an introduction by D'ARCY THOMPSON. Translated by J. N. ROSTOVTSOW. London: Constable and Co. 1926. Pp. 477. 28*s*.

LUCK, cunning or law? To Darwin it was the good fortune of happening on a variant which suited the surroundings and had a survival value in getting through the sieve of natural selection. To Samuel Butler it was the ingenuity of learning what had happened to one's ancestors and storing it in an unconscious memory. To Dr. Berg the live world in its course of evolution is carrying out a predetermined plan controlled by laws as definite as those which keep the developing individual in the proper path. He brings abundant experience as a naturalist and an extraordinary wealth of learning to enforce his arguments for orthogenesis on the one hand, and for the direct influence of environment on the other. An evolutionary series is comparable to an individual—simple and small to begin with, growing progressively larger and more complex as it progresses, and finally reaching extinction in some gigantic gerontic form. Palæontology apparently contains abundant examples of the process, and if we interpret them as evidence of predestined courses, inherent in each animal and plant, it is obvious that our common views on evolution need modification. So, too, Dr. Berg attributes the similarity of animals of diverse groups living in the same environment to something deeper than chance variation. He is, in short, rather heretical, and he has written a most refreshing independent attempt to make out just where we stand in evolutionary matters. Prof. D'Arcy Thompson's introduction is delightful.

GOULD'S MEDICAL DICTIONARY.

By G. M. GOULD, A.M., M.D. Edited by R. J. E. SCOTT, M.A., B.C.L., M.D. London: H. K. Lewis and Co., Ltd. 1926. With illustrations. Pp. xi. + 1398. 30*s*.

THE first of Dr. George M. Gould's dictionaries was published in 1890, and in various forms they have had a large circulation ever since. The latest appears under the new title of "Gould's Medical Dictionary," edited by Dr. R. J. E. Scott, and has definitions of some 76,000 words. In a preface to one of his earlier volumes Dr. Gould referred to the medical vocabulary as a "strange hodge-podge of the medical language of two or more thousand years and of many special national tongues, in mechanic, not chemic mixture, with modern sounds and symbols, the whole amazingly heterogeneous and cacophonous," and it is alarming to find that the reviser of this dictionary has had to add another 5000 "legitimate new terms" to his collection. The lexicographer's position is difficult because it is his duty to interpret all the words which his readers may come across, and he has little chance of purifying them in the fire of his philological enthusiasm. Before his comments can appear the worst words are already on a thousand lips, and though the mortality amongst scientific terms is high their deaths are generally caused only by overcrowding due to the delivery of others worse than themselves. Dr. Scott remarks incidentally that no name should be changed simply because it is inappropriate; its suitability should be canvassed thoroughly before it is applied—a custom which would save much of the confusion of modern medical terminology. Only thus can be checked the growth of what Dr. Gould rightly calls the "huge and unassimilated philologic mass, many times greater than it should be, the despair of medical students and of the makers of dictionaries."

Attention is drawn to the steadily increasing use of proper names, legitimate and otherwise. Where these

are attached, for instance, to operations which have represented a real advance in method, their employment may be justified and of historical value. But the multitude of names used in medicine is so great that it is hopeless to try to remember more than a few.

This dictionary is unusual in giving pictures of many medical authorities of various centuries and countries, a custom which will be acceptable to some readers, but not to others. It is well produced and not very large considering the immense amount of information given. But a glance down the pages, filled with such words as "archocolpocystosyrinx" (more commonly known as recto-vesico-vaginal fistula), may well make the reader wish for an international Academy, which should quietly take such useless words away and give them decent burial. It ought to be possible in this way to reduce the medical vocabulary by half, and no one would be more thankful than the compilers of dictionaries.

THE HOUSE SURGEON'S VADE MECUM.

Second edition. By RUSSELL HOWARD, C.B.E., M.B., M.S. Lond., F.R.C.S. Eng., Surgeon to the London Hospital; and ALAN PERRY, M.B., M.S. Lond., F.R.C.S. Eng., Assistant Surgeon to the Hospital. Revised and enlarged. London: Edward Arnold and Co. 1926. Pp. 520. 12*s.* 6*d.*

IN the preparation of the second edition of his popular book, which first appeared in 1911, Mr. Russell Howard has had the help of Mr. Alan Perry. The book has been extensively revised. Among other improvements is the introduction of many excellent photographs illustrating various splints and appliances for the treatment of fractures. The chapter on anæsthetics has been revised by Dr. Ashley Daly and a very useful medico-legal chapter has been brought up to date; throughout this chapter the use of the term "municipal hospital" for rate-aided institutions prevents confusion. This handbook should prove useful not only to dressers and residents in hospitals, but also to those practitioners who have not had the advantage of holding the post of house surgeon in a big hospital.

INTESTINAL INFECTIONS.

Les Enteropathies Microbiennes. By Prof. G. SANARELLI, Directeur de l'Institut d'Hygiène de l'Université de Rome. Paris: Masson et Cie. 1926. Pp. 227. 3*s.* 4*d.*

IN this suggestive volume Prof. Sanarelli summarises the results of a lifetime of bacteriological study. To him perhaps more than to anyone else we owe the modern conception of typhoid infections as general diseases with elective localisation of the organisms in the small intestine rather than as primary infections of the small intestines with general symptoms. As he himself expresses it, "typhoid fever is no more a disease of the intestine than small-pox is a skin disease." These views have to some extent been popularised by the investigations of Besredka and his pupils, and some part of the present volume is occupied by discussions of priority of investigation, but the bulk of the work deals with the general pathology of typhoid, cholera, and anthrax, and the reader will here find a store of interesting records. An excellent bibliography is included.

HÆMATOLOGY.

Pernicious Anæmia, Leucæmia, and Aplastic Anæmia. An Investigation from the Comparative Pathology and Embryological Point of View. By J. P. MCGOWAN, M.A., M.D., Pathologist to the Rowett Research Institute, Aberdeen. London: H. K. Lewis and Co. 1926. With 12 illustrations. Pp. 116. 7*s.* 6*d.*

STARTING from his investigations of the leucosis of fowls, on which Ellermann and others have written a good deal, and of the curious anæmia of suckling pigs, which may be cured by adding iron to the diet of the mother, Dr. McGowan has added another to the long list of books which try to make out the genealogy and relationships of the fascinating cells of the blood and bone-marrow. This central idea is that the stem cells from which red cells and leucocytes arise may be stimulated in a variety of ways so that elementary forms of one grade or another appear in the marrow in abnormal numbers and overflow into the circulating blood. In this way he finds a common basis for perversions such as pernicious anæmia and leukæmia which in their fully developed forms appear as sufficiently distinct diseases. Dr. McGowan's discussion is full of interest and his facts mostly come from an abundant personal experience. His propositions and conclusions are not always proved beyond doubt; but, which is perhaps better, they are put forward in a vigorous and stimulating way and will give his readers some fresh ideas.

PRACTICAL ULTRA-VIOLET LIGHT THERAPY.

A Handbook for the Use of Medical Practitioners. By T. CLYDE MCKENZIE, M.B., Ch.B., and A. A. KING. London: Ernest Benn. 1926. Pp. 108. 6*s.*

THIS excellent little book has evidently been written by those who have themselves studied the subject and who know how to hand on really useful information. It is not a treatise but a practical manual written for doctors who want to use this form of therapy. Certain parts of the subject, as, for instance, the technique of open arc lamps, are hardly touched; this is perhaps a pity, but if it is assumed from the outset that the scope of the book is limited to the authors' own experiences, the reader will suffer no disappointment and will find much useful information on technique and on treatment. They will also find that the authors have a theory to account for the action of ultra-violet radiation on the body; they suggest that it acts upon and through the nervous system. They make out a very good case for their theory that these rays have an effect upon the nervous system, but we are no more inclined to believe that the whole sequelæ to irradiation arise in this way than we are to accept the photo-electric theory or that which imputes to the blood stream the chief part in these complicated processes. Perhaps hardly enough facts are yet known to warrant adhesion to any single theory; but that is no reason to refrain from formulating suggestions, for these point to further experiment, which, in turn, may reveal the weaknesses of the theories which inspired them, while stimulating progress in another direction.

"OVER FRAYS."

An Original House for Practical People. By CLARICE H. M. NAYLOR-DAVIDSON. Uxbridge: Printed privately for the author. 1926. With photographs, plans, and other illustrations by the author. Pp. 66. 21*s.*

Mrs. Davidson, the wife of a medical man who has retired from practice, being impressed with the necessity of having a house which, while eminently sanitary, shall be capable of being run without domestic assistance, describes in this book such a house which she herself has designed. In construction it is a brick parallelogram 68 ft. by 24 ft., and has two stories and an attic in the roof. The long sides of the parallelogram face nearly east and west—i.e., slightly south of east and north of west. All the sitting-rooms have windows opposite one another on the S.E. and N.W. sides respectively and so has one bedroom. The chief feature of the house is the kitchen which opens straight out of the dining-room with sliding doors in between. The cooking-stove is a gas stove, also fitted with a hot-water circulator, and besides its own flue there is a cast iron canopy over the stove fitted with a ventilator opening into the chimney flue, all smell being thus carried away. In all the rooms the walls meet the floor with a curved skirting, making dust easily removable. The fireplaces in all the rooms are arranged for gas, but they are constructed in two halves, so that by a swinging arrangement on either side an ordinary grate

is exposed which can be used for wood or coal. The walls of the house are double, with an air space between, thus avoiding damp, and the house is warmed by hot-water radiators. Cupboards built into the walls are plentiful and all bedrooms are fitted with wash-hand basins fixed and supplied with hot and cold water from taps. A small greenhouse in which is the hot-water cylinder opens out of the kitchen at one end of the house, and at the other end the garage adjoins the drawing-room. In every way the house bears out its designer's description as being one for practical people.

BOOKS FOR NURSES.

Hints to Probationer Nurses in Mental Hospitals. Second edition. By RICHARD EAGER, O.B.E., M.D. Aberd. London: H. K. Lewis and Co. 1926. Pp. 88. 1*s.* 6*d.*

THIS little book fills a real need and will appeal to the earnest probationer who seeks practical guidance and theoretical interest in mental nursing. It fulfils admirably its aim—that of putting in clear and simple language the essential points a nurse should know immediately on entering a mental hospital; it gives such an account of the mind, its working, and manifestations in conduct as will enable her to perform her duties with an intelligent understanding of mental disorder. Of the 88 pages 38 are given to practical hints, while 50 deal with psychology; an increase of the first part would be an improvement in order that rudimentary facts about the handling of patients might be more fully discussed. The book begins admirably with the essential maxim: "Never take offence at a patient," and the last maxim reads: "Never let a patient suffer because he is unable to complain." The rules given are wholly suited to the probationer. The section on ward duties might usefully lay more stress upon the duties peculiar to the probationer. Tube-feeding, catheterisation, the giving of enemata, &c., will be practised and taught by a senior nurse; but it is often the probationer's duty to learn to persuade her patients to eat by understanding their fears or other reasons for refusal, and to report on the excretory functions, watching for a distended bladder, or for constipation, preventing needless incontinence by timely attention, and avoiding discomfort by prompt cleansing of a soiled bed. It may be noted that the rule about "seclusion" has now been altered. A valuable addition would be a section showing how large a part is played in treatment by the hospital environment in general, and by the relations between staff and patients; the nurse cannot learn too soon her ability to help in treatment that every word and gesture may have an effect on the patient, even when apparently unnoticed.

The book is of handy size, and every junior nurse should enter on her work with it in her pocket and study it thoroughly in her leisure hours.

A Handbook for Nurses. Seventh edition, revised. By J. K. WATSON, M.D. Edin., Capt. R.A.M.C. London: Faber and Gwyer. 1926. Pp. 802. 7*s.* 6*d.*

Dr. Watson's handbook has again been revised and brought up to date. The chapter on digestion and dietetics has been enlarged, the Schick test is well described in the section on diphtheria, and new sections are devoted to the use of insulin in diabetes and to the discussion of anaphylaxis. Nurses will find this a useful and well-illustrated text-book at a reasonable price.

The Nursing of Diseases of the Nose, Ear, and Throat. By MICHAEL VLASTO, M.B., B.S., F.R.C.S., Assistant Surgeon to Ear, Nose and Throat Department, West London Hospital. London: Faber and Gwyer, Ltd., 1926. Pp. 229. 6*s.*

THIS little volume presents an adequate review of diseases of the nose, ear, and throat from the nurse's point of view. It begins with a useful description of the out-patient department and of the nurse's duties there, and goes on to explain in simple language the commoner diseases and operations, lists of the instruments necessary for these being provided. More stress might have been laid on the importance of keeping a child well over on the side after an operation for removal of tonsils and adenoids, thus making sure that hæmorrhage is not going on, the blood being swallowed. Some manipulations, such as syringing the nose and fauces and the contra-indications for the first-named process might well have been more fully discussed. The book is clearly written and well illustrated, and will be useful to nurses.

JOURNALS.

BRITISH JOURNAL OF CHILDREN'S DISEASES. Vol. XXIII. July-September.—In a paper on the diagnosis of cerebellar tumours in children Dr. Macdonald Critchley states that the four main symptoms of cerebellar growths in children are in order of frequency—vomiting, headache, disorders of equilibration, and visual disturbances. Another occasional symptom is the so-called "cerebellar fit," which is preceded by no aura or premonitory symptoms, but consists in generalised tonic rigidity of the entire musculature. The physical signs may be classified into those due to actual cerebellar disturbance, such as atonia, ataxia, and asthenia, those due to pressure upon adjacent structures, such as squint and paralysis of cranial nerves, and those due to generalised hydrocephalus, which include enlargement of the cranium and separation of the sutures. Tumours primarily pontine may be distinguished from tumours primarily cerebellar by the late occurrence of drowsiness, by the absence of dysphagia until a very late stage, by the early appearance and rapid development of papilloedema, the late occurrence of cranial nerve palsies and spasticity, and the rarity of sensory loss. —Dr. T. Brushfield and Dr. W. Wyatt contribute the first part of a paper based on a study of 16 cases, dealing with the clinical aspects of epiloia, a term suggested by Sherlock to describe the syndrome of mental deficiency, epileptic fits, adenoma sebaceum, nodular sclerosis of the cerebral cortex, and tumours of the kidney and other organs. Three illustrative cases, accompanied by some striking photographs, are recorded.—Dr. F. Parkes Weber deals with the question of infantilism as a complication of congenital hæmolytic (acholuric) jaundice or anæmia, with a record of personal cases and a review of the literature. —Dr. Parkes Weber also contributes a note on the neoplasm and infection theories of leukæmia and aleukæmic lymphadenoses.—Dr. G. W. Ronaldson reports a case of measles at confinement with a subsequent modified attack in the child. The term "congenital measles" was not applicable to this case as the baby did not develop any symptoms until 15 days after birth. Extraneous sources of infection could be excluded in the child's case, as the patients were treated in a two-bedded room in an isolation block, where there were no other cases of measles. Ronaldson attributes the somewhat prolonged period of incubation and the rudimentary character of the disease to the immunising effects of the maternal milk.—Dr. S. Erdheim contributes a paper entitled Second Attacks of Measles. An account of two cases, which presents the following points of interest: (1) The subjects were brothers. A familial predisposition to recurrence of measles has been noted by other observers. (2) The interval between the attacks was almost exactly one year in each case. (3) The second attack of one child was more severe than his first attack. This is contrary to the generally accepted opinion that the second attack is milder than the first, as was the case in the other child. (4) There was nothing anomalous or characteristic in the clinical pictures of the second attacks.—Dr. Erdheim also reports an example of "illness of infection" in measles, in which the primary illness lasted two or three days and commenced 13 days before the appearance of the eruption.—The abstracts from current literature are devoted to diseases of the new-born.

THE LANCET.

LONDON: SATURDAY, OCTOBER 23, 1926.

RESEARCH IN GENERAL PRACTICE.

GENERAL practitioners are often reminded that they are the backbone of the profession. The praise, of course, is gratifying; but it does not prevent them wondering how much work is to be left for them to do. Public health, tuberculosis, infant welfare, and venereal disease have one by one been "rescued"—as one writer is pleased to put it—from the morass of general practice, and it has lately been suggested that midwifery should also be taken out of this supposedly septic environment. The family doctor, in fact, is finding his practice less and less general every day, even when his panel duties are taken into account, and it is not surprising that sometimes he dislikes the change, since it is in varied responsibility well discharged that doctors must find their chief satisfaction. Some alteration of the work, however, was inevitable. The everyday demands of general practice are so great as to make it impossible for any but exceptional men to keep an up-to-date knowledge of more than a few of the special branches of medicine. The work has to be done under difficulties, for constant interruption, or the fear of it, is of all things most antagonistic to serious reading. If the practitioner is trying to hold his own against all the conflicting currents of medical progress, how can he find time to strike out in a particular direction of his own? How can he undertake original investigation or follow up a line of thought? Lack of leisure, intellectual isolation, and inadequate facilities conspire to prevent him from collecting information and recording his ideas, and there is no doubt that scientific medicine has thus suffered a considerable loss, for it is in general practice that the early stages of disease and the late results of treatment may best be studied. As has often been pointed out, there is in general practice a great opportunity for research—an opportunity largely disregarded. It is only the family doctor who can follow the history of individuals during 30 or 40 years, summing up the hereditary and prenatal influences, the effects of wrong habits in childhood, the final results of infantile and youthful ailments, and the first causes of premature decay or death. To him also come the minor ailments—the colds, catarrhal fevers, and influenzas, the mild exanthems, the medical dyspepsias, and septic conditions such as boils and styes and carbuncles; he has a better chance than any surgeon to judge of the after-effects of operations for such conditions as cancer, gastric ulcer, hæmorrhoids, or varicose veins. Obviously it must be in the interests of science that the general practitioner who has been given an inquiring mind should be encouraged to make the most of his many opportunities, and it only remains to consider how this can best be done.

A possible solution to the problem has recently been propounded by Miss M. FORRESTER-BROWN in an article of considerable interest.[1] For that fundamental hindrance to research, lack of particular knowledge, she sees but one remedy—specialisation. Although the practitioner is to retain cases of acute disease or trivial complaints beneath his own care, so as to keep in touch with the conditions of their homes and save himself from too narrow an outlook, "it should be provided," says Miss FORRESTER-BROWN, "that every chronic case of more than a few weeks' duration would be automatically grouped under a practitioner specially experienced in such disabilities," who "would have at his back the consultant staff of some large institution, and would be the regular attendant, both at their homes and at the clinic, of large numbers of chronic cases of the particular group, which would give him a wide experience of all the phases, such as is unobtainable by specialists under present conditions." "Once the public are educated to demand specialisation," she remarks, "they will not long permit any doctor to treat a chronic case outside his own branch"; but she does not say how long it will take to educate them, and it is on the ground of reasonable prejudice the scheme would be wrecked. Most patients would prefer to go to a doctor whom they know and trust rather than to a man with special knowledge whom they do not know and would fail to see the coöperation between the general and special adviser implied in the design. It is hard to imagine, moreover, that a medical man would readily recommend an old and devoted patient whom he had attended all her life and in all her confinements to go to his local rival—of whom, perhaps, they both disapproved—merely because she had a patch of eczema and the rival was the skin authority for the locality. The effect of such extensive specialisation on the work of the profession is not easy to imagine, but perhaps we may learn from the results of similar differentiation in the infantry towards the end of the war. Company parades were reduced to a handful, as nearly everyone was away on "specialist" courses, and one man was heard to remark pityingly to another: "Of course, you wouldn't understand why I don't go on parade, you being an infantryman. Well I'm a specialist."

The remuneration of general practice is such that to make a competence a doctor must work hard and to make a good income he must overwork grossly or be able in his own practice to grasp all the advantages to science as well as to routine by coöperative business management. Original work involves a loss of leisure or money by one who usually has neither to spare. There are some, however, who would not be deterred from investigation by thought of time or money but are, nevertheless, discouraged by two other factors mentioned above—isolation and lack of facilities. The number of cases of any one condition that a general practitioner may meet in a given time is small and he is properly shy of publishing inconclusive results. If he knew that others were working on the same problems and that results could be published together, he would be less reluctant to undertake research. Most diseases, however, nowadays require some laboratory work for their investigation, and the general practitioner has neither time, knowledge, nor apparatus for carrying this out. The outline of a scheme for overcoming these difficulties was put forward not long ago by Dr. N. M. GOODMAN. He suggests [2] that each of the great teaching hospitals should enrol a number of its old students, now in general practice, who would be able and willing to undertake research. An expert at the hospital would be in charge and would coördinate the work, and the practitioners would be recompensed for their loss of

[1] Practitioner, September, 1926.

[2] THE LANCET, 1926, i., 735.

time by a system of retaining fees. The hospital would carry out any laboratory work needed, and the director would supply references to the literature and undertake experiments suggested. From time to time he would report progress and he would be responsible for collating results and arranging their publication. The working of this scheme may be illustrated by an example. Whilst many practitioners in conducting labour apply forceps as soon as the head is in the vagina, others consider that everything should be left to Nature where possible and that the forceps should never be applied in a normal delivery. An honest report by a group of 20 to 30 general practitioners on the late results of both methods might throw valuable light on a question which remains unnecessarily controversial. We should be glad to see Dr. GOODMAN'S scheme adopted as an experiment by some teaching centre, but it must be remembered that the collation of information received from only half a dozen independent workers may present great difficulties, and that in general practice, as elsewhere, there are only a few men who are likely to have the due bent for research. Although the public has come to regard any and all research work with a sort of mystical respect, the profession ought not fall into that error, remembering that the only real justification of such work is its success—whether positive, negative, or merely catalytic. The ideal organisation is that which places tools in the hands of the man who can use them—and into the hands of nobody else.

ACCIDENTS AND HOSPITALS.

THE after-history of broken bones and other accidental injuries has long exercised the minds of surgeons who have followed up these cases to their final issue. Nearly 20 years ago the late Mr. CLINTON DENT devoted an annual oration at the Medical Society of London to an account of his personal experience, which was that a fracture of the leg, owing to its after-effects, was from the point of view of wage-earning capacity a very serious injury. Such a fracture, under the most favourable circumstances, kept a man from following efficiently an active employment for six months, and it constantly happened—the words are Mr. DENT'S own—that these patients broke down on resuming work and remained permanently incapable of following it, as a direct consequence of the injury. Simple fractures, as they are ineptly called, excited but little interest in the hospital practice of Mr. DENT'S time, and were hardly as closely supervised by the visiting surgeon as cases of more pronounced clinical value. On another occasion Mr. DENT stated that in his long experience as a police surgeon he had never seen a case of Pott's fracture, treated at a general hospital, so completely restored as to permit of a constable's return to active duty. What was true of London 20 years ago seems to have its more recent parallel in other cities. Our Vienna correspondent recently set out the reason for the foundation of an accident hospital in Vienna; it was because the Viennese insurance societies came to realise that they were paying enormous sums just for the want of immediate and adequate aid for the victims of accidents. So they decided to provide a number of beds in charge of a specially trained staff prepared to investigate every fracture and to apply all the resources of orthopædic surgery and mechanotherapy. The statement that this Vienna accident hospital in its first year saved the insurance societies something in the neighbourhood of £18,000 is astonishing enough, but should be read in the light of Mr. WARREN LOW'S remark (see p. 849) that under the present hospital system many patients fail to make economic use of function which has actually been restored.

The treatment of accidents in hospitals raises many difficult questions, some of them new and urgent. Before the era of the motor-car the receiving officer of a large general hospital might be embarrassed by a run of Pott's fractures on the first snowy evening of the year: to-day a fine Sunday evening may overwhelm any cottage hospital with a glut of complicated injuries. And it does not follow that the routine appropriate for the one institution is ideal for the other. In most general hospitals accident cases are under the care of the resident medical staff with only the supervision deemed needful from the visiting surgeons. To collect the cases under one control and in one department would no doubt make for convenience, but would tend to withdraw these instructive cases from the view of the student and from the care of those junior men in whose training the direct responsibility for their treatment plays such an important part. The middle course might be taken of centralising in one department all accident cases, serious and trivial alike, with wards and treatment rooms, under the charge of a whole-time resident of the standing of a registrar. Accidents would be admitted in normal rotation under the nominal charge of members of the visiting staff, and those members who were interested in these cases would visit the department, accept responsibility for the cases under their names, and use them for purposes of teaching. The director would be responsible for the organisation of the department and for the treatment of all cases not specially reserved, and he would give special courses of instruction. Unless some such plan as this is adopted the treatment of injuries is likely to be relegated to a special department and will cease to be a part of general surgery, and anyone can see that this would be a regrettable position for the public. The cost of establishing such a department would no doubt be considerable, but this might well be defrayed by the insurance companies.

At the present time, as Sir JOHN PAGET has recently insisted, it is a grave scandal that these companies contribute nothing towards the treatment of their injured clients in hospital, although in cases where they are treated privately the cost of medical treatment is a part of the accident policy. Moreover, their present attitude to the hospitals is short-sighted since the funds of insurance companies must suffer materially from inefficient treatment, even if not to the extent which they were found to do in Vienna. Both equity and self-interest alike should lead the companies to support an accident department in every hospital with such an open hand that the other funds needed for the work could be found readily; such an arrangement would probably be more satisfactory than to meet the need by the erection of special clinics, independent of general hospitals, where the contributing companies might seek to minimise disabilities and to discharge patients as fit for work long before this was the case. On the other hand, as Mr. LOW points out, after-care centres should be useful in helping the victims of injuries to overcome diffidence in their recovered powers. A lax system may prevail at some general hospitals, and may tend to swell the numbers under treatment by the presence of some who would be better back at work, and in this connexion it would be interesting to hear the views of patients on the rigour of the Vienna system.

AN ANTHROPOLOGIST ON JOHN BULL.

THE first social evening of the session was held at the Royal Society of Medicine on Monday last, when a very large company of Fellows and guests were received by Sir JAMES BERRY, the President, and Lady BERRY. The speaker of the evening was Sir ARTHUR KEITH, who entitled his witty and entertaining address John Bull: a Study in Anthropology. He took as his text the familiar John Bull of BERNARD PARTRIDGE, remarking that not only was the famous *Punch* artist the son of one anatomist and father of another, but also he had drawn John's features with peculiar racial and anatomical insight. The artist, he said, could convey with his pencil that John is bluff, honest, kind-hearted, and generous, with a hearty contempt for everything savouring of pretence, meanness, or dishonesty. The anthropologist with his craniometer, on the other hand, had as yet found no precise method of recording or measuring these characteristics. John is dolichocephalic, but has rather a massive brain. His face shows none of the sharpness and angularity of certain other British types. TENNIEL'S John Bull was an old, old man, but since then he appeared to have grown gradually younger. In the year 1712 the Scotsman, Dr. JOHN ARBUTHNOT, in his "History of John Bull," described the character he had selected as the essential Englishman and to whom he had given this name.

"In the main," he said, "John Bull was an honest, plain-dealing fellow, choleric, bold, and of a very inconstant temper; he dreaded not Lewis Baboon (France) either at backsword, single falchion, or cudgel play; but then he was apt to quarrel with his best friends, especially if they pretended to govern him; if you flattered him, you might lead him like a child. John's temper depended very much upon the air; his spirits rose and fell with the weather-glass. John was quick and understood his business very well; but no man alive was more careless in looking into his accounts, or more cheated by partners, apprentices, and servants. This was occasioned by being a boon companion, loving his bottle and his diversions, for, to say truth, no man kept a better house than John nor spent his money more generously."

A second Scotsman, JAMES GILLRAY, an audacious and brutal caricaturist, developed John Bull from a loose-jowled, putty-faced farm labourer, as he had drawn him, into a typical country publican. Although many of GILLRAY'S drawings showed a very different conception of John Bull from those of ARBUTHNOT and TENNIEL, yet some of them certainly foreshadowed *Punch's* John Bull. The lecturer demonstrated with photographs of English public men how rare in fact was this "typical Englishman," and suggested that he was met more often in Yorkshire than elsewhere.

Neither in face nor colouring was John Bull, he said, a true Saxon, and to find his prototype it was necessary to go far back in our island story to certain immigrants early in the second millennium B.C. These ancient invaders appeared to have originated beyond the Caucasus, where big noses and round heads still abound, and their blood can be traced, said the speaker, chiefly among our landed, professional and business men. While the typical John Bull is not uncommon in Ireland, he is almost unknown in Scotland and on the continent. Hostile French cartoonists gave John Bull a lantern jaw, loose lips, a rabbit mouth, defective chin, and sharp nose, and this caricature accurately represents the anthropological changes which the faces of the British people are most apt to undergo. German artists in the stress of war picked out the prognathous jaw, ample mouth, shrunken snub nose, and cruel countenance occasionally found among prosperous and unprincipled city men. Despite these attempts to crystallise the essentials of English character in one symbolic figure, the supply of individual types remains inexhaustible, as artists and novelists reveal every week, and before anthropologists lies the tremendous task of reducing this complexity to a scientific unity.

Among the interesting exhibits in the library of the Royal Society of Medicine were a collection of X ray photographs and engravings of medical men.

Annotations.

"Ne quid nimis."

THE BEST USE OF FEVER BEDS.

AT its meeting last week the Metropolitan Asylums Board decided on a change of policy in the allocation of beds in hospitals to the various prevalent infectious diseases. Of the total 4185 beds then occupied in M.A.B. hospitals, 2285 contained patients suffering from diphtheria, 1527 from scarlet fever, 194 from whooping-cough, 106 from enteric fever, 34 from measles, 21 from puerperal fever, and 18 from other diseases; the beds allotted in special hospitals to ophthalmia, marasmus, small-pox, tuberculosis, post-encephalitic and convalescent cases are not included in these figures, which, as will be seen, bear no relation to the relative fatality of the various infections. Out of every million people living in London during the last 15 years, 251 have died annually from measles, and only 42 from scarlet fever, the mortality-rate per cent. in the Board's hospitals during the same period being 10·6 for measles and 1·5 for scarlet fever. When the Board decided at the beginning of this period—that is, in 1910—to receive measles and whooping-cough it was with the definite intention of restricting their admission to the number of beds available after the prior claims of scarlet fever and diphtheria had been satisfied. As far as diphtheria is concerned, the claim remains paramount, but so mild has been the type of scarlet fever in London during recent years that the Board believe the large majority of these cases would have recovered whatever the conditions under which they were treated. Moreover, the value of isolation in the treatment of scarlet fever is by no means established, although it is possible that the more severe complications, such as nephritis and otitis media, may occur less often in hospital than in patients treated at home. Even under non-epidemic conditions it would be impracticable to isolate all the cases of scarlet fever, diphtheria, and measles in the metropolis, and to do so would require enormous expenditure on new buildings during an epidemic period, when the number of measles cases may run up to 100,000 in the year; but the ratepayer may quite properly inquire whether he is well-served by an expenditure of 1*s.* 4*d.* per head per annum on the simple isolation of all cases of scarlet fever, when the case-mortality of this disease has gone down from 10 per cent. in the 'seventies to less than 1 per cent. at the present time. Having such considerations as this in view, the Metropolitan Asylums Board, with the approval of the Ministry of Health and the local authorities concerned, have decided to modify the present scheme of allocation of beds, so as to give measles a considerable proportion of the beds now allocated to scarlet fever. As soon as the one competes against the other for admission, the borough medical officer of health will select cases of either in accordance with the necessities and home conditions of the individual case. This decision fulfils a principle, already enunciated in these columns, that while no sanitary authority should or could undertake the isolation of all infectious disease in its area, its utility would be greatly enhanced if it could undertake to deal with selected cases of all kinds, putting in the forefront those from institutions and from poor homes, the new cases in a locality and all those of severe type. It might be feared that such a re-allocation would increase the difficulties of preventing cross-infection, but recent experience of bed-isolation at Fazakerley and other places shows that this problem may not be as difficult of solution as was once supposed.

SIR THOMAS HORDER'S ADDRESS.

THROUGH an inadvertence in the publishing department of THE LANCET an advance copy of our issue last week became prematurely accessible to the public. As a result an address by Sir Thomas Horder was reproduced in the lay press on Thursday evening, in contravention of promises made by the British Medical Association. We deeply regret the occurrence. The incriminated copy of the paper was sold over the counter through a direct breach of rules, which we believe never before to have been broken. The fact that the breach was innocent does not, unfortunately, remove either the mischief done or the chances of misinterpretation.

THE HEAT PRODUCTION OF NERVE.

PHYSIOLOGY, in the guise of the "handmaid to medicine," often receives the lip-service of the medical profession. Yet little or no notice has been taken in medical journals of one of the most remarkable achievements in experimental physiology that has ever been recorded.[1] Prof. A. V. Hill, of University College, London, is already well known for his investigations of heat production in muscle, a piece of work which earned for him the Nobel Prize. He has now followed this up, after years of patient experimenting, by actually measuring the heat produced in a nerve during the conduction of a nervous impulse. It was long believed by many physiologists that the nerve-fibre acted as a passive conductor of the impulse, since no heat production could be detected. Prof. Hill's ingenuity has, however, at length overcome the technical difficulties of the problem, and he has shown that the heat liberated amounts to 0·000 069 calories per gramme of nerve per second of stimulation. The greater part of this heat is produced during the period of recovery after the stimulation has ceased, a fact which was quite unexpected and which opens up fresh lines for the study of nerve function. The means by which this minute amount of heat was measured can be briefly indicated. Prof. Hill had already used thermopiles of extreme sensitivity for his previous work on muscle. The amount of heat produced in a nerve was found, however, to be so infinitesimal that the movement in the galvanometer connected with the thermopile could not be seen. The beam of light from the galvanometer was therefore directed on to a second thermopile which thus amplified the movement in a second galvanometer and rendered it visible. Other difficulties to be overcome lay in the insulation of instruments so delicate from thermal and electrical changes coming from without. Only, it seems, during the early hours of Sunday morning are the subterranean chambers in Gower-street, where the experiments were conducted, immune from gross interference by outside agencies. It is obviously impossible to assess what will be the value to medicine of this remarkable achievement in the field of physiology. Its direct value is probably nil, but its indirect value may be enormous.

ALCOHOLISM IN ANCIENT GREECE AND ROME.

ON Oct. 12th Dr. J. D. Rolleston gave an interesting address on Alcoholism in Ancient Greece and Rome at a meeting of the Society for the Study of Inebriety. He pointed out that as the scientific study of alcoholism dates only from the middle of the nineteenth century very little is to be gleaned from contemporary medical writers as to its prevalence and effects in classical antiquity. The chief sources of information are the poets, especially the gnomic writers, such as Theognis; the satirists, including Horace, Juvenal, Martial, Lucian, and the Greek Anthology; philosophers and moralists, such as Plato, Plutarch, and Seneca; and most of all the two encyclopædic writers, Pliny the elder and Athenæus. As an adherent of the Stoic philosophy Pliny (A.D. 23–79) constantly inveighed against the luxury and corruption of the age; he devotes an eloquent chapter in his Natural History to the subject of drunkenness, and many others to the different varieties of wine and their therapeutic uses. Numerous remedies for the prevention or cure of inebriety will also be found in his pages. Athenæus, who flourished at the end of the second and beginning of the third century A.D., is of special interest to the medical reader, said Dr. Rolleston, in that he has preserved fragments which have not otherwise come down to us of medical and lay writings dealing with the subject of inebriety. In particular he makes several quotations from lost works on drunkenness by Aristotle and his disciples, Theophrastus and Chameleon of Heraclea, as well as from a lost play by Menander on drunkenness and one by Alexis entitled the Wine-bibber. Numerous chapters in the Deipnosophists of Athenæus are devoted to the enumeration of wines and drinking vessels, celebrated drinkers, the evils of wine, and cognate subjects. Some idea of the prevalence of drinking in classical antiquity may also be gained from the contemporary proverbial philosophy relating to drunkards and the numerous synonyms, both in Greek and (to a lesser extent) in Latin, for a bibulous or drunken man.

The drinking of unmixed wines at banquets among the Greeks and Romans, Dr. Rolleston pointed out, was regarded as the sign of a barbarian or a boor, and the mixture of wine with water or snow in various proportions regulated by the master of the feast was carried out in a large bowl from which the wine was distributed to the guests. Both in Greece and Rome the festivals connected with the wine god served as an excuse for widespread intoxication, and finally gave rise to such scandalous excesses that a decree of the Senate was passed forbidding any Bacchanalia being held in Rome or throughout Italy. Apart from festivals the Greeks and Romans of the classical period were, on the whole, remarkable for their sobriety in contrast with certain contemporary nations, such as the Scythians, Carthaginians, Iberians, Celts, and Macedonians, who were notorious for drunkenness. Though there is some indication of the existence of chronic alcoholism, as is exemplified by passages in Pliny and Seneca and in the lives of certain individuals, such as some of the Roman emperors, alcoholism in classical antiquity was mainly of a convivial character, and industrial alcoholism, apart from that associated with prostitution, was unknown. Dr. Rolleston quoted several passages from the classical writers dealing with the dysgenic influence of alcohol and other evil effects of drink on the community and the individual, especially the relation of inebriety to insanity, crime, and poverty, and the measures, often of a fanciful character, recommended by the ancients for the prevention and treatment of drunkenness. In conclusion, he showed that the alcoholism of classical antiquity differs from that of to-day by its predominance among the upper classes, the lack of legislative control, the absence of distilled liquors, which were not introduced until the fifteenth century, and the non-existence of syphilis, which in modern times is often contracted under the influence of alcohol and is liable to run a severe course in alcoholic subjects.

RHEUMATISM IN CHILDHOOD.

IT is encouraging to learn that the efforts now being made in this country to solve the complex question of the rheumatic disease of childhood have their countertype in America. Dr. Thomas T. Mackie, of New York, has contributed to the August number of the *American Journal of the Medical Sciences* an analytical study of 393 cases of rheumatic fever and 89 cases of chorea. Dr. Mackie goes to the root of the problem when he emphasises "the growing conviction that rheumatism is essentially a chronic, often a very slowly progressive disease, having periods of activity and latency which are strikingly parallel to the clinical course of tuberculosis and syphilis." As to types of the disease, he defines an acute form with multiple arthritis, fever, and leucocytosis, and a

[1] Proceedings of the Royal Society, 1926, c., 223.

chronic form, with less well-marked symptoms but chronic cardiac disease; there is also the chorea group, in which females predominate. First attacks of rheumatism are infrequent below the age of 5 years and reach their maximum age-incidence between 10 and 15 years, whereas chorea starts earlier—between 5 and 10 years of age in most cases. Here follows an interesting result of the analysis, for whereas in rheumatic fever the incidence of heart disease in a first attack is at its maximum between 5 and 10 years of age, in chorea it occurs more frequently, case for case, at the later ages, reaching a maximum at the time when chorea itself is less frequent. This aspect of the inquiry may be summarised by saying that the younger a child has its first attack of rheumatism, the more likely is that attack to be accompanied by carditis, while the older it is in having a first attack of chorea, the more likely is carditis to occur. Next comes the more practical question: "How long after the subsidence of an acute phase of the disease must one wait before having a reasonable certainty that potential cardiac damage has completely declared itself?" This question is, of course, bound up with the solution of the whole rheumatic problem, and it is to be feared that the answer to it is, from the economical point of view at least, a depressing one. Most observers will concur in Dr. Mackie's statement, that infection of the heart may "be both chronic and progressive and yet give little or no evidence of its presence for a period of years." This melancholy conclusion, however, carries with it the eminently practical procedure of periodic examination of rheumatic patients, even when apparently cured. With regard to the criteria as to whether active infection has been arrested or not in a given case, Dr. Mackie considers that observation of temperature, leucocyte counts, and especially electrocardiographic studies are necessary to ensure a correct régime of treatment. It is a pity he does not amplify these points in detail, since a valid criterion of latent infection would determine the question of treatment by rest-homes in a given case. In this country more stress has been laid upon the pulse-rate and the cardiac physical signs than upon blood and electrical examinations. With regard to infected tonsils, Dr. Mackie contributes another group of analysed cases, the observation of which leads him to find that whereas 42·5 per cent. of those cases, in which tonsillectomy was performed after a first attack, had later a recurrence of rheumatic fever, no less than 60 per cent. of unoperated cases relapsed within a period of three years or so. We do not know, however, whether hygienic measures, other than tonsillectomy, were taken to prevent recurrence in these cases. His last series of observations, which deal with the interval between the first attack and the first recurrence, and take account only of acute attacks of polyarthritis, forces Dr. Mackie to restate his concept of rheumatism as a "chronic, slowly progressing disease characterised by intervals of calm simulating and periods of activity which entail further damage." Unobtrusive symptoms, such as anæmia and slight muscle pains, may be the only warnings of a process of the utmost gravity; hence salicylates, in producing only symptomatic relief, may be a positive danger in that they confer a sense of false security.

THE TEACHING OF ENTOMOLOGY.

EVERY layman is familiar nowadays with the importance of insects as porters of disease. If there were no mosquitoes, fleas, or tsetse-flies the world would be a much healthier place. And man's power to control insect-borne infections can generally be exercised much more effectively against the insect than against the infectious agent itself. For when we have to deal with small things which occur in multitudinous numbers it is easier to affect them by changing their environment than by direct attack; the plague bacillus is embarrassed by taking away part of its habitat, the flea, and fleas are dealt with more simply by destroying their habitat, the rat, than by catching them with a piece of soap. To know what to do when some insect is implicated in the spread and maintenance of some disease, we must know all that is known (and will probably want to know a good deal more) about its life and habits, and entomology has now added a practical utility to its function of edification. There are, too, some striking instances of how the utmost refinements of entomology may be needed. The mystery of why Madras has escaped plague in all the years it has prevailed in most of the rest of India was solved by the discovery of the flea experts that the common rat-flea there is not *Xenopsylla cheopis*, as had been supposed, but another very similar species, *X. astia*, which had been confused with it. Those who are interested will find in the last number of the *Annals of Applied Biology* (vol. xiii., 1926, p. 402) an account by Dr. A. D. Imms of the successful control of seven or eight insect pests in the Hawaiian Islands by the introduction of other insects which fed on or parasitised them. Indeed, the case for the importance of entomology is overwhelmingly strong. It was stated to the International Congress of Entomologists at Zürich by Dr. H. S. Fremlin, of the Lymph Department of the Ministry of Health, and his paper is printed in their Transactions (vol. ii., p. 344). Insects are, he says, one of the great world menaces, and he asks that something should be done to secure that entomology is taught in every school. It is evident that no one ought to grow up without knowing that caterpillars turn into pupæ and pupæ into butterflies. And it is comforting to realise that a great deal is done already throughout the country to enforce a knowledge of insects of that order. Children nowadays generally know a good deal more about such matters than their parents, who went to school before "nature study" had been invented. What they get is, no doubt, slight, but it is a basis to which more can be easily added later if necessary, and, quite apart from the time-table, we doubt whether the application of entomology to the suppression of disease is a subject of any great educational value.

TOWARDS AN INTERNATIONAL CONGRESS OF OPHTHALMOLOGY.

AT a general meeting of the Convention of English-speaking Ophthalmological Societies, held in London in July, 1925, it was resolved to empower its President, Mr. E. Treacher Collins, to appoint a standing committee of five, whose duty it should be to coöperate with other ophthalmological societies in promoting international congresses. This committee, consisting of Prof. Edward Jackson (Colorado), Sir John Parsons, Dr. G. A. de Schweinitz (Philadelphia) Mr. Leslie Paton, with Mr. Collins as chairman, considers that the time has now come to take steps to form an international committee. It is desired that each nation should be represented by two delegates nominated by arrangement between the principal ophthalmological societies of the nation, or, in the case where no national ophthalmological society exists, by representative ophthalmologists, and invitations to nominate delegates have been sent out. The proposal is that the international committee shall meet at The Hague in July next year. It may be recalled that before the war, 1914–18, international ophthalmological congresses met every five years, the first being held in 1857 before the International Medical Congress was established. One was due to have been held at Petrograd in 1914, but was abortive. In 1922 an attempt was made by the Ophthalmological Society of the United Kingdom to revive the meetings, but international memories rendered it of no avail. The move which began last year at the London convention will have its fruition when a representative international committee has again come into being. The primary function of the committee when formed will be to arrange for the next international congress. In the meantime it is proposed to obtain such coöperation as is possible in promoting international action in relation to the prevention of contagious

ophthalmia, the establishment of uniform methods of recording tests, and the interchange of ophthalmological literature.

MENTAL DISORDER IN SCOTLAND.

THE twelfth annual report [1] of the General Board of Control for Scotland shows that the problems before the Scottish Commissioners are very similar to those occupying the minds of their English colleagues.[2] The first subject discussed is the early treatment of mental disorder and the necessity of providing facilities for voluntary admission to mental hospitals. We have noted in previous issues the obstacle which certain parish councils have opposed to scientific advance by their refusal to forego the Government grant allowed for certified patients. As long ago as 1890, however, the parish council of Glasgow inaugurated hospital wards for the treatment of temporary and incipient mental disorder, and their example has been followed by the councils of Govan, Paisley, and Dundee. It is interesting to note that the observation wards at Duke-street and Stobhill (Glasgow) have done such good work that the erection of a third asylum for the district has not been considered necessary. Although there are only 160 beds, 1176 patients were admitted during last year and less than a third of these were eventually certified. The provision of out-patient clinics, which is being pushed with such vigour in England and Wales, is still very inadequate in Scotland. The Glasgow General Dispensary and Western Infirmary are the only clinics at present in existence, but one is to be established at the Royal Infirmary, Edinburgh. Scotland, like other countries, has found that open-air treatment has reduced the high incidence of tuberculous infection among mental patients by one-quarter.

On the whole it must be admitted that Scottish mental hospitals are behind the southern ones in the extent to which they have been "hospitalised"—at all events in name; the retention of the words "asylum" and "lunatic" in this report and throughout the country is an indication that there is yet much to be done. Very few district institutions have a visiting specialist staff; some are even run without a resident medical officer at all, while others have inadequate medical or nursing staffs. No reference is made to any system of discharge on trial or money grants. Nevertheless, as a rule the Board have been supported in their efforts by the district boards and medical officers. Many institutions now have properly equipped dental rooms and a visiting dentist; some of the larger ones have ultra-violet light and hydrotherapeutic installations. The report suggests that these expensive plants, and also clinical laboratories, should be established only in certain accessible centres and at the expense of groups of district boards. The problem of occupational therapy is dealt with in the first place, naturally, by providing work in the hospital grounds. Twenty-two of the district asylums have farms, and the Board have suggested that every institution should have a minimum of one acre to each male patient. For those who cannot be employed in farm or garden the Brabazon Society continues its valuable work. The ladies who belong to this society visit the hospital once a week to instruct the patients, and occupational therapy has also been established in asylums where there are no voluntary workers. It is now possible for all public authorities to send their cases of encephalitis lethargica to Stobhill, where special treatment and research can be carried out.

In a 15-years' review of the statistics the Board point out an apparent but not a real decrease in certified persons. The discharge- and death-rates have not appreciably altered in the three quinquennial periods, and there is, on the whole, a striking uniformity in the statistics, except for an increase in the death-rate during the war. This reflects the sensitiveness of asylum patients to the mental and physical stress of war conditions. From 1910 to 1914 there was an average of 546 mental defective patients at the two institutions; in 1919 the number had risen to 1680 in 14 institutions. It is this certification of mental defectives under a different Act that accounts—and more than accounts, in the opinion of the Board—for the diminished number of cases registered under the Lunacy Act. A census of all the mental defectives throughout the country showed that there were last year 12,969 registered persons. Apart from those under the control of the education authorities there was a total number of 2202 who had not been certified and who did not come under the statutory powers of the Board, and there is a waiting list of 250 for the institutions. The boarding-out system appears to be working satisfactorily. When comparison is made between the paragraph on mental defectives in this report and the anxiety expressed by the English commissioners the doubt arises whether Scotland is yet fully aware of the gravity of her mental deficiency problem.

On Jan. 1st, 1926, there was in Scotland a total of 18,537 insane persons under cognisance, an increase of 139 during the year. Only 597 voluntary boarders were in residence on the same date. The death-rate for the year was 8·6 per cent. The report does not discuss the problem of nursing, but leaves its readers to deduce the state of affairs from the bald facts that 1020 attendants and servants resigned during the year (being 93 less than the year before), 134 left without notice, 41 were dismissed for incompetence, and 98 for misconduct.

"DOCTOR 'MY BOOK.'"

THIS is the somewhat enigmatic title of a play by Mr. Rudolph Cordova, collaborating with his wife, who writes as Miss Alicia Ramsey, which is a feature of the current issue of the *Tatler*, and is published in connexion with the press movement during the past week in support of the funds of St. Bartholomew's Hospital. If the title is difficult to understand there is nothing obscure about the play. It is a series of dialogues between the great Abernethy and a succession of patients and their friends who consult him, the dialogues being constructed to illustrate, as their common object, the great man's known character and notorious eccentricities. The types of Abernethy's visitors, therefore, have been selected to form obviously dramatic contrasts, and to permit the introduction of familiar anecdotes displaying Abernethy's brusqueness towards those who magnified their trifling ailments, and extreme kindness and generosity towards those who could ill afford his fees. The aptness of many of the episodes will be recognised by medical men as founded on much of the medical history of the time, in which Abernethy bulks so largely; but we do not know what the authority may be for attributing to Abernethy himself habits of gluttony, though the humour is obvious, from the playwright's point of view, of allocating such personal habits to the great public prophet of the ills which follow upon abuses of the intestinal tract. Undoubtedly the play should arouse the interest of a wide public in the prosperity of the great institution where Abernethy, the prime exponent of John Hunter's revolution of surgical outlook, so long reigned paramount, and the reproduction of Lawrence's famous portrait of Abernethy, which hangs in the hall of the hospital, is a striking one considering its scale.

RADIUM THERAPY OF CANCER OF THE CERVIX.

THE attitude of most surgeons at the present time to the use of radium in the treatment of carcinoma of the cervix was recently defined by Mr. T. G. Stevens in THE LANCET (Oct. 9th, p. 769). They hold that radium applications should be reserved for clinically inoperable or borderline cases, in the belief that extended panhysterectomy gives better results in operable conditions. He went on to point out that there are no data yet available to confirm or disprove

[1] H.M. Stat. Office, 1926, pp. 48. 2*s*.
[2] THE LANCET, Sept. 11th, p. 557.

this impression, since no large series of operable cases have been treated by radium alone, and that it is quite possible that with increasing experience the technique of radium therapy will so improve as to make it the method of election even in operable cases. We suggested six months ago [1] that since with the technique now used in some clinics the results in inoperable cases are so remarkable, the time is ripe to check the ceaseless sporadic attempts at variation and still further improvement of the methods of applying this new weapon, and to persuade at least some of those who are using it to limit themselves to an extensive trial of some agreed standard technique in a series of cases. This course has been adopted by the group of medical women entrusted by the Medical Research Council with the use of 300 mg. of radium bromide lent by the British Empire Cancer Campaign for research purposes. The first report of the Cancer Research Committee of the London Association of the Medical Women's Federation has now been issued [2] and merits praise for the clear way in which the problem is discussed and for the admirable coördination of work conducted in four hospitals inconveniently far apart. The standardisation of the treatment was made possible by the appointment of a research officer in the person of Dr. E. Hurdon, who sees every case, advises on special points, and is responsible for the case records and follow-up system. She was asked first to make a detailed survey of the literature, limiting her inquiries to those clinics at which the fate of a relatively large number of cases had been followed for at least five years after treatment. The important result of these inquiries forms Part I. of the report, and those who are interested in the present world position of radiotherapy in cancer of the uterus will find it clearly summarised in ten pages, including some 50 references to original papers. After studying the information collected by Dr. Hurdon the committee decided to adopt, with certain modifications, the methods which have been in use for 15 years at the Radium Hemmet, Stockholm, under the direction of Dr. J. Heyman. In the records from this clinic the "absolute cures" (Winter's requirements)[3] amounted to 20·29 per cent. in 375 inoperable cases of cancer of the cervix, the primary mortality being 1·19. The technique adopted by the committee, modelled on that used by Dr. Heyman, is set out in detail. After preliminary preparation of the patient, which may involve cystoscopy to exclude cases in which the bladder is involved, the vagina is disinfected and dilated and tissue is taken for microscopic examination. Two tubes of radium in tandem are then inserted into the utero-cervical canal. Flat applicators are placed in contact with the growth in the lateral vaginal fornices, and anteriorly or posteriorly as indicated. The vaginal applicators are kept in place by a firm gauze pack, which also serves to protect the vaginal mucous membrane, and to prevent the bladder and rectum from too close contact with the radium. Three applications are made, the second one week after the first, and the third two weeks after the second. The length of time of each application is 22 hours; 50 mg. element are used in the uterus and 50–70 mg. element in the vagina. The total dose varies between 5000 and 7500 mg. element hrs. The number of cases of cancer of the cervix treated thus during the first six months was 42, of which six were operable.

It is far too early to discuss results for, as is pointed out in the report, an early complete disappearance of local signs is in accordance with general experience and cannot serve as a basis for an optimistic prognosis. The work done under the auspices of this Cancer Research Committee has not been confined to cancer of the cervix; six cases of cancer of the uterus are under treatment, and one case of cancer of the vulva. It is noteworthy that the majority of the patients did not consult a physician until the disease was far advanced, and, moreover, that in more than 25 per cent. the average time elapsing after consultation before a local examination was made was seven months. Some were receiving medical attention for a year or 18 months before an examination was made. The reluctance of patients to submit to a vaginal examination at the hands of the family practitioner is well known, and cases of abnormal bleeding of vaginal discharge are often referred to medical women for this reason. This fact, and the efforts being made to conduct the investigation by medical women into the therapeutic scope of radium on scientific lines, should secure an adequate response to the appeal being made for funds to prosecute and develop the work.

[3] G. Winter (1923): Zentralbl. f. Gynäk., xlvii., 1084. The requirements for determining "absolute cures," which were adopted, are: (a) All cases which come to the clinic to be included. (b) All fatal cases to be enumerated. (c) Observations to extend over a period of five years. (d) No deductions to be allowed.

POSTURE AND ANÆSTHESIA.

THE importance of a correct posture of the patient during operation has long been manifest and attention has also been given to the position in which he is placed when returned to bed. In a contribution to the *American Journal of Surgery* for August Mr. Willy Meyer emphasises the dangers of material aspirated into the lungs during or soon after operation and draws attention to the value of the Trendelenburg position as a preventive measure. The value of correct posture during operation is not confined, however, to its efficacy in preventing aspiration. The position in which the patient is placed has an important bearing on the proper performance of the circulation and particularly on the due blood-supply to the brain. Dr. Leonard Hill has laid stress on the influence which gravity brings to bear in the distribution of the blood during full anæsthesia. The vasomotor mechanism is paralysed by which in ordinary life alterations of position are prevented from leading to too extensive accumulations of blood in the dependent parts of the body or too scanty a supply to those which are raised. Consequently, a low position of the head in formidable operations is as necessary for the patient's welfare from the point of view of keeping the cerebral circulation sufficient as it is for the purpose of avoiding aspiration of mucus or saliva into the air passages. When the operation involves the risk of blood or pus entering the air passages posture is, of course, of prime importance and properly managed can keep the larynx free from invasion even without the electric sucker which is now so commonly employed in these circumstances. Position, indeed, is really more reliable than the sucker, which is not immune against sudden choking. Referring to bronchitis after ether anæsthesia, Mr. Meyer quotes Prof. A. Bier for the novel treatment by intramuscular injections of 8 drops of ether in an equal amount of sterilised olive oil. This is said to be effective by making the bronchial secretion more liquid. It is an interesting suggestion in view of the diametrically opposed and strongly recommended practice of treating these patients by the use of atropine or belladonna.

LAST Monday, at 4 P.M., Sir John Rose Bradford, President of the Royal College of Physicians of London, delivered the Harveian oration, which is printed in full in this issue of THE LANCET. He then presented the Bisset-Hawkins medal for 1926 to Dr. A. T. Stanton, principal medical officer to the Federated Malay States, and director of the Government laboratories, whose work has thrown so much light on the difficult subject of the ætiology of beri-beri. This medal is bestowed triennially upon some duly qualified medical practitioner who is a British subject and who has during the preceding ten years done such work in advancing sanitary science or in promoting public health as in the opinion of the College deserves special recognition. Previous recipients of the medal have been Sir Ronald Ross (1914), Sir Arthur Newsholme (1917), Sir William Hamer (1920), and Sir Thomas Legge (1923).

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXCIV.

THE TREATMENT OF SENILE INSANITY.*

II.—SENILE MENTAL CONDITIONS.

SENILITY, like presenility, is a relative term and cannot be defined with any accuracy. In this article mental deterioration appearing from the early 'sixties to the end of life is that to which the term senile dementia is applied. The treatment and care of a case of simple senile dementia will be first considered, afterwards the special features of presbyophrenia, senile confusion and delirium, and senile dementia associated with arterio-sclerosis and certain neurological disturbances will be discussed.

Simple Senile Dementia.

This condition is an exaggeration of our common inheritance, if life be sufficiently prolonged, that is, dotage. There is loss of memory for recent events, increasing inability to recognise faces, an egotistical outlook, and a failure to consider the needs of others. Change is intolerable; the same food, the same chair, the same comforts must all be available at the instant they are required. Reminiscences of the scenes and activities of youth are repeated ad nauseam, and there is a progressive failure of comprehension for private and public affairs. These mental changes are accompanied by the well-known physical regression, the wrinkled skin, loss of hair, failure of strength, nocturnal wandering, and somnolence by day, until "last scene of all, that ends this strange eventful history, is second childishness, and mere oblivion—sans teeth, sans eyes, sans taste, sans everything."

It should be possible to treat the simple senile dement successfully in home surroundings. If there is no responsible relative who will undertake his or her care, homes can be found, where for a moderate payment the senile patient is adequately cared for. The practitioner should make careful inquiries before advising reception into such institutions. Many poor persons will have to find a shelter in Poor-law institutions. Every effort should be made to prevent old patients from ending their days in an institution for the insane.

Rules for the Management of Simple Senile Dementia.

It will be the duty of the practitioner to frame certain simple rules for home nursing.

The bedroom is best situated on the ground floor, or at any rate, the first floor of the house. Slippery polished surfaces, loose mats or rugs, must be avoided as a fall may easily result in a fracture. Arrangements must be made to accompany the patient up and down stairs. Open fires must be provided with guards, and it may be well to block the lower sashes of windows on the first floor if the bedroom is upstairs. A commode in the sitting-room and bedroom is useful. Disinfectants must not be left lying about in the water-closet. A punctual routine in the management of the senile patient is important.

The *diet* should be light, especially at night, the principal meal being taken at midday. Meat should only be allowed once, and should be minced in the more advanced cases. It is better not to give food in between meals; instead the intervals between meals may be shortened and their number increased. Some patients will be difficult to persuade to take enough food, others are voracious and eat too quickly and too much. Milk, eggs, fish are all suitable. Meat, raw vegetables, and raw fruit should be curtailed. Wine may be allowed, and tobacco permitted after food. Whatever arrangements are made, punctuality in serving is essential. If there is a tendency to frequency of micturition at night, fluids should be reduced to a minimum after 6 P.M. The evening meal should be light, and eaten at 7 P.M. at the latest. Early hours must be kept and 9 P.M. should see the patient retiring to bed. Male patients may be allowed a urine bottle within reach, so that it is not necessary to get out of bed to micturate. Nocturnal restlessness is in some cases a great difficulty, and is often worse with women, who choose the early hours to get up and go dusting. A cot with high sides may be tried, but there is always the risk of an active patient trying to climb over the sides. A box mattress on the floor is safer. The bedding should be generous, and bed socks of wool invariably worn. Hot bottles are advisable in the winter months.

Exercise.—A daily walk should be taken, with an escort, a necessary precaution in towns or in the neighbourhood of main roads. Care must be taken to see that the clothing is warm, and that wool is worn next to the skin. A woollen waistcoat or jumper should be worn in the autumn, winter, and spring seasons. Easterly winds are a menace to all senile patients, and with the wind in that quarter outdoor exercise may be foregone. Patients who are too feeble to walk may be taken for drives. A horse-drawn vehicle is more suitable for senile persons than the rapidly moving car.

Insomnia.—The best hypnotic is alcohol. Hot whisky and water, or brandy and water seem to produce the best results, but well-warmed claret or burgundy may serve. If alcohol fails several hypnotics may be tried. Paraldehyde ʒ i. or ʒ ii. is safe, and its taste rarely resented by the senile patient. Medinal gr. vi. or gr. x. may be used for long periods, is easily administered, and without risks. Amylene hydrate, ʒ ss. to ʒ i., is also satisfactory. Sulphonal, chloral, and bromides are contra-indicated. Patients who wake in the early hours of the morning will often drop off after a glass of warm milk or some patent food.

Restlessness is seldom extreme in the simple case. Bromides, if used at all, are useful here. The following mixture is suggested for occasional use:—

Potass. bromid. gr. xv.,
Spt. ammon aromat. ℥ xv.,
Aquam chloroformi. ad ʒ i.,
ʒ i. s.o.s. ex aq.

Tr. opii 10 to 20 drops three times daily is often most effective in controlling restlessness. The dose may be increased and only gradually diminished when it has fulfilled its purpose. A warm bath is an admirable measure, and will often promote sleep.

Constipation is a troublesome feature of senile dementia. There should be no hesitation in prescribing an enema, especially where there are signs of agitation and restlessness, common results of constipation. Ext. cascara liq. ʒ ss. to ʒ i. at night seems to suit senility. A freshly made infusion of two or three senna pods is another good nightly draught. Oily preparations are not suitable, and salines will often upset patients and make them sick. Small doses of calomel, gr. ½ every hour up to gr. iv., give good results. A suitable laxative should be adhered to when it is found.

Observation.—Constant watchfulness must be impressed upon those responsible for the care of a senile dement. Not only are there dangers from falling and wandering but such patients are notoriously careless with fire. Matches and spills used by smokers must be dealt out sparingly. Shaving may present difficulties also. Some member of the household will usually undertake the task with a safety razor. A nurse or male attendant will be a great help in the management of simple senile dementia.

Presbyophrenia.

This is a variety of senile dementia in which there is a profound disturbance of memory and orientation. The patient becomes absolutely lost in time and space, fails to recognise his or her relatives, and fabricates freely, relating the most impossible experiences. Some develop ideas of persecution, and may become abusive and threatening to others. On the whole, they are suggestible, and can be managed at home. The treatment differs in no way from that of the simple form, save that extra vigilance is necessary. A temporary removal to a hospital may become advisable, and is an event for which the relatives should be prepared.

Senile Confusion or Delirium.

In this class are found the cases that give most trouble to the practitioner. They are unreasonable, often hallucinated, suspicious, and impulsive. Extreme wandering is common, suicidal attempts occur, and assaults upon others result from delusions of marital infidelity or paranoid ideas. Refusal of food may also arise, and is of grave import in an old patient. The need for institutional care is evident, and should be urged by the physician in charge. Such cases prove an unfair burden to any household, and it is remarkable how often removal from home produces improvement, and may lead to an early return of the patient to home surroundings. In emergency great excitement may be controlled

* An article in this series on the Treatment of Presenile Mental Disorders appeared last week.

by one or at most two injections of morphine hydrochloride gr. ¼ and hyoscine hydrobromide gr. 1/120 or 1/150. Hyoscine should on no account be continued.

Senile delirium is a condition which suggests a terminal infection, and is nearly always fatal.

Senile Dementia Associated with Arterio-sclerosis and Neurological Disturbances.

Arterio-sclerosis may be a prominent feature of senile dementia. Cerebral hæmorrhages and thromboses occur. Convulsions (senile epilepsy) are not uncommon. Headache may be a constant complaint. Convulsions are treated with a prompt enema, an injection of morphine, followed by a few doses of the sedative mixture already suggested. If the fits continue lumbar puncture will often relieve them. Nitrites and iodides relieve headaches, and help most patients materially. The arterio-sclerotic changes in the vessels of the cord may produce spastic paraplegia, sensory losses, retention or incontinence of urine and fæces, and trophic sores. Absolute cleanliness in nursing is essential, together with a diurnal toilet of the skin over bony prominences with spirit and an antiseptic powder. Actual sores must be dressed twice daily with a mild astringent lotion. An air or water bed will have to be procured. Some patients complain of severe cramps in the legs, which may be due to cord lesions, or arterio-sclerotic changes in the vessels of the limbs, often accompanied by intermittent claudication, a limp in walking. A useful mixture to relieve these pains is :—

Potass. iodid. gr. i.ss.,
Spt. ætheris nit. ℥ xv.,
Syr. tolut. ℥ ss.,
Aquam ad ℥ ss. t.d.s. ex aqua.

Parkinsonism and chorea may both occur in senile dementia. Hypochondriasis is the outstanding feature of the mental state of paralysis agitans. Treatment will not be considered here, but it may be noted the continued use of hyoscine to relieve Parkinsonism has been known to produce a confusion accompanied by hallucinations.

The Senile Delinquent.

Reference must be made to the treatment of delinquency, though it consists in maintaining an adequate control. Sexual excitement may be an unpleasant feature of senile dementia. Improper advances to girls, or boys, exhibitionism and various other indecencies occur in any form of the disorder. Homicidal attacks and suicidal efforts are more common than is generally admitted. If adequate control cannot be secured at home, certification must be advised, where it is possible. In any case, if deterioration is advanced, and antisocial acts a frequent occurrence, the presence of such a patient imposes an intolerable burden on most households, and may have a most undesirable influence upon younger generations.

Medico-legal Points.

Practitioners may be called upon to give evidence as to the testamentary capacity of a senile dement. The important points to remember are that a medical colleague should be called in, that each physician should preferably obtain two interviews, and that notes made at the time of the examinations should be carefully kept. The practitioner should ascertain whether or not the patient understands the nature and extent of his property, and how and why he intends to dispose of it. The presence or absence of delusions, and the degree of orientation should be noted. In giving evidence the physician should beware of being trapped into an attempt to define the difference between normal senescence and senile dementia. Lastly, it is often forgotten that the affairs of a senile dement may be controlled, without certification, under Section 116 (*d*) of the Lunacy Act. Application to the Master in Lunacy should be made through solicitors, and must be supported by medical affidavits.

Special Articles.

THE MOTOR SHOW AT OLYMPIA.

SOME SPECIAL FEATURES.

IN reviewing last year's show we ventured to suggest that the intense competition between manufacturers of moderate-priced cars could hardly last. Actually it seems to be fiercer than ever, and to be entirely unaffected by industrial trouble. Not only have the prices of many cars been still further reduced, but the cars themselves are better and more lavishly finished and fitted than ever. Hardly any old favourites are absent, and many models and some makers appear for the first time.

One of the most interesting features is the extraordinary cheapness of small covered cars. This is the first show when the small coupé or saloon is really within the reach of the smallest purse that is capable of buying a car. "Open" cars, on the other hand, have such good hoods and side screens and close so tightly that even those who have constantly to face inclement weather conditions will not suffer much inconvenience. Four-wheel brakes are the rule rather than the exception, and balloon tyres and shock absorbers are fitted to the cheapest models. It is not possible to offer advice except in the most general terms to the medical buyer. Price and quality run very closely together, and the more the doctor pays for a car of a given power the better balanced is its engine and the more carefully finished are its gears likely to be. He can also, if he wishes, spend extra money to obtain the undoubted advantages of real leather and pneumatic cushions, and in various accessories. But even the cheapest cars do not fall below a certain minimum of quality, and that minimum is higher than anyone would have considered possible five years ago. Probably nearly every car in the show, except some of the quite experimental models, can be trusted to give satisfaction for years if reasonable care is used.

Cheap Cars.

For the first time in history there is a £100 car. Pre-war attempts never produced at this price anything that could really be looked on as more than a "cyclecar" but the 8 h.p. Gillett gives promise of being good value. It is made by the Ensign Co., who have produced a limited number of very good 12 h.p. cars, and has a four-cylinder engine, four-wheel brakes, and a self-starter. It is, however, hardly past the experimental stage, and will not be seriously marketed before next April. The nearest approach to the £100 mark, therefore, continues to be the Trojan at £125 with short body and solid tyres. There is also a full four-seater at £140, and pneumatic tyres cost £5 extra on either model. The medical man of limited means might do much worse, as the car is suspended on four long cantilever springs, holds its top gear like an American six-cylinder car, has full all-weather equipment, and a device for starting the engine from the driver's seat. Its only drawbacks are the low speed and a tendency for the front wheels to skid on a greasy surface. The well-known 7 h.p. Austin is down to £145, and is better than ever; it does 45 miles to the gallon and is twice as powerful as it looks. The triangular war between Morris, Clyno, and Citroën continues apace, and all three sides have extra attractions to show. The Morris-Cowley is now hardly recognisable, for it is dark blue, with a flat radiator somewhat like that of the Rolls, which gives much better cooling than the old type. The wheelbase is four inches longer and the four-seater has a correspondingly longer body of the "bath" type, with adjustable and separate front seats. Smith shock absorbers replace the Gabriel snubbers. The prices are £148 10*s.* for the two-seater or £160 with four-wheel brakes; £182 10*s.* for the coupé, and £195 for the saloon. All Clynos now have four-wheel brakes. The standard two-seater costs £160 and the

four-seater £172 10*s.*; the "Royal" models, with their more luxurious equipment, £195 and £199 10*s.* respectively. The four-door saloon costs £230. The Citroën 11·4 (built in this country) is sold as a four-door four-seater with four-wheel brakes for £165, and a four-door saloon for £210. There is little to choose between these three makes. The medical man who wants a car at this price should try them all before he decides.

"Twelves" and "Fourteens."

The range of choice in this group is immense. "Twelve" means nowadays something a little bigger than a Morris-Cowley, and "fourteen" the lower edge of the big car class. Cars in this group are designed with a view rather to quality and luxury than to a minimum price, and every one is equipped with almost every accessory and convenience that a professional owner can find a use for. Low or medium pressure tyres and four-wheel brakes are universal. The following are a few examples out of perhaps a hundred. The Austin 12 is one of the happiest designs ever executed. Although some subtlety in its dignified proportions suggests a large car, it is only slightly bigger than the ordinary "11·9." It is sturdy enough, however, to carry quite a roomy saloon. The two-seater costs £275, and other models proportionately more according to the elaboration of their coachwork. Hillmans have always made good cars, and the Hillman 14, introduced for the first time last year, was their first attempt at something beyond the light class. It amply maintains their reputation. The touring car at £275 is the cheapest model, but there is a beautiful four-door saloon at £345. Humbers have put a two-litre engine into their last year's 12 h.p. chassis and made it into a 14–40. This firm have too much experience to be likely to commit the mistake of overrating the strength of one of their frames; the 12 h.p. engine was powerful enough, and the new model should be a treasure. Another new two-litre car is the Cluley. This firm already makes a 14–30, and their 1927 14–50 is distinguished by a 4 ft. 8 in. track and an overhead valve engine of over two litres capacity. The design is conventional, and the gear-shift, as on most English cars of this size nowadays, is on the off-side. The price is £400 for the saloon, a very good bargain. The 14–30 costs £295 both as a two- and a four-seater.

Small "Sixes."

There are, of course, many small six-cylinder cars already on the market, such as the A.C. and the Talbot, but this autumn brings several new ones, some of them at a price low enough to be tempting. They are fascinating cars to drive, as they have a smooth silky pull and can be driven through traffic and round blind corners at a walking pace on top gear. The A.C. 16–40 is very light for its power, and with the handy "Aceca" coupé body costs £455. The new Talbot 14–45 is priced at £415 for the two-three-seater. In addition to the virtues which every Talbot car possesses, it has some cleverly thought-out equipment, such as a direction indicator with red arrows a foot long (possibly anticipating future legislation), a switch for the near-side headlamp, and exceptionally easy adjustments for the brakes. An interesting new-comer is the Brocklebank 15, which is to be sold as a saloon only at under £400, a price which will allow it to compete with the American models. It is obviously designed by men of great experience and has hydraulic four-wheel brakes. The new Singer six should be ideal for the medical man, as its price is only £350 as a saloon. The upholstery is pneumatic, and there are four wide doors that can be locked. It has all the usual luxury equipment and more.

Accessories.

In these days of traffic congestion buffer bars have ceased to be an example of American eccentricity and have become an insurance policy against minor collisions, for they take about 15 miles per hour off a shock. They are quite decorative, and some rear buffers can be combined with luggage grids. They are well worth fitting on a valuable car that is to be exposed to constant town driving. Double-bar models vary in price from £7 10*s.* to £3 5*s.*; single-bars from £5 to 45*s.* The Andre Popular model is the cheapest.

Nothing is quite so necessary to the doctor, especially in winter, as some kind of thermostatic device to enable the engine to warm up quickly and to remain warm. The simplest device of this kind is a radiator jacket, costing from 15*s.* to 25*s.*, and a more ambitious one is a metal shutter on the Venetian blind principle, costing between 40*s.* and 60*s.* The Benjamin Electric Co. make very good ones, and also make the Boyce Motometer, by which the driver can keep track of the water temperature. Some sort of thermometer is vital if a muff is fitted and is desirable in any case. It costs a guinea. There are also small thermostatic valves at 30*s.* or so for fitting between engine and radiator to control the flow of water. It is possible to buy a spotlight for 17*s.* 6*d.*, and very useful accessories these are, especially if they have a driving mirror on the back and 12 ft. of flexible lead, so that they can be carried about round the car. 50*s.* will obtain a good one.

Conclusion.

The doctor cannot do better, before he goes to Olympia, than to study the *Autocar* show numbers, the first of which, dealing chiefly with accessories, appeared on Oct. 8th. This week's issue contains a guide to the show, in which the car exhibits are described and their positions at Olympia indicated for the benefit of visitors. A price classification of cars is a feature that will be appreciated by all who are seriously thinking of buying a car and have to consider the monetary side. The issue of Oct. 29th will give a full illustrated account of the exhibition and will constitute a valuable record of what appears to be one of the most interesting automobile shows ever held.

MEDICINE AND THE LAW.

Dangerous Drugs Act Prosecution; Important Submissions for Defence.

AT Marlborough-street police-court on Oct. 15th Lieut.-Colonel John Kynaston was committed for trial at the Old Bailey on a charge raising important issues. He had been summoned for aiding and abetting, counselling, and procuring Rowland Pawsey, registrar of marriages, Marylebone, to attempt to obtain possession of a dangerous drug (powdered opium) contrary to the Dangerous Drugs Regulations, and also for falsely using the descriptions M.R.C.S. and L.R.C.P. Lond., implying that he was a registered medical practitioner on August 23rd, contrary to the Medical Act, 1838. The prosecution alleged that the accused treated Mr. Pawsey for catarrh and handed him a prescription at the top of which were the words "late R.A.M.C., L.R.C.P., M.R.C.S.," while at the bottom, after his signature, were the words "Lieut.-Colonel R.A.M.C., retired, M.R.C.S., L.R.C.P. Lond." The prosecution stated that Lieut.-Colonel Kynaston's name had been removed from the lists of the two colleges indicated and from the Medical Register. The defence took the following points. First, it was submitted that, as Mr. Pawsey could not be convicted of an unlawful attempt to obtain a prohibited drug (since Mr. Pawsey did not want such a drug and did not care whether he got powdered opium or powdered rhubarb), therefore Lieut.-Colonel Kynaston could not be convicted of aiding or abetting him. Secondly, it was urged that the Dangerous Drugs Regulation mentioned in the charge was ultra vires because the Act never authorised the Home Secretary to make a regulation dealing with an attempt to obtain possession of a dangerous drug. Thirdly, in relation to the alleged offence against the Medical Act, it was submitted that the preamble to the Act showed that Parliament thereby intended to distinguish qualified from unqualified practitioners. The accused had been a fully qualified practitioner

ever since 1885. He was placed upon the Register in that year and he remained registered for over 40 years. He had served with the R.A.M.C. from 1886 till his retirement in 1905 and again during the Great War. In 1922 the General Medical Council had removed his name from the Register for alleged advertising amounting to "infamous conduct" in a professional respect. But nothing that the General Medical Council or the colleges could do could prevent Lieut.-Colonel Kynaston from saying that he was to-day a fully qualified medical man. He could not issue death certificates or hold certain public appointments specified in the Medical Act, but, apart from these and other limited disabilities, he was at liberty to practise.

Mr. Cancellor, the stipendiary magistrate, asked if it was submitted that the defendant was entitled to use the letters "M.R.C.S." Mr. Edmond O'Connor, appearing for the defence, was not prepared to answer in the affirmative, but reiterated that Colonel Kynaston was a fully qualified medical man. The magistrate adjourned the second summons sine die but committed the defendant for trial on the first, sending the case to the Old Bailey in view of the importance of the submissions made by the defence.

Successful Action for Fees.

Medical practitioners' services in particular contingencies cannot be uniformly appraised like items in a grocer's catalogue. When a doctor sues a patient for services rendered, the law assumes that the work was not done for nothing and the jury—or, in the absence of a jury, the judge—is asked to say what is the proper remuneration for the work, having regard to the nature and extent of the work and the standing of the practitioner. Any instance, therefore, of a court awarding a doctor a particular fee for a particular service is not to be taken as a universal rule; it does not follow that the same or another court would necessarily award the same sum for the same service in another case. Nevertheless, in practice a certain measure of standardisation is bound to be established, and the fee awarded to a particular doctor is of interest to other doctors. In a recent case in the Llandudno county court Dr. S. L. B. Wilkes sued the executors of the late Mr. R. E. Lloyd, of Colwyn Bay, to recover his charge for two medical certificates. Mr. Lloyd had fallen ill and died shortly afterwards. Dr. Wilkes was called in and on his report to the coroner an inquest was deemed unnecessary. Two insurance companies required a medical report. Dr. Wilkes's claim for fees included a charge of a guinea for each report. The executors took the view that the two reports should have been priced at half-a-guinea each. They, therefore, paid into court a sufficient sum to meet his claim, less one guinea. This meant that, if Dr. Wilkes did not recover a larger sum than the amount so paid in, he would lose the costs of his action from the date of the payment into court. The judge, however, awarded him the full sum claimed. A medical man, observed His Honour, was not like a solicitor whose fees were fixed by scale. The plaintiff was an M.D. of London and the charge of a guinea for a certificate by him was not out of the way at all. As already explained, this decision does not mean that a doctor will always be able to recover a guinea in the same circumstances, but it is important as indicating that in those circumstances the charge of a guinea was considered reasonable.

Hair-dresser's Licence Revoked; Alleged Exorbitant Charges for Scalp Treatment.

Sir Chartres Biron at Bow-street police-court lately upheld the action of the London County Council in revoking the licence granted to an establishment for facial and scalp massage, chiropody, and electrical treatment. It was stated that a visitor to England from Canada went to the shop of Mr. Joseph Caplan, a Charing Cross hair-dresser, last December and was induced by an assistant to have a course of four applications of special treatment for the scalp at a charge of £1 11*s.* 6*d.* He was also sold a bottle of lotion and a pot of ointment with an arrangement for future supplies. In all he was charged £7 18*s.* 3*d.*, though according even to Mr. Caplan's own valuation the charge should have been less than one-third of that sum. It was suggested that the customer was induced to pay an outrageous price by the pretence that he was suffering from a disease of the scalp when in truth and in fact he was not so suffering at all. For the hair-dresser it was stated that, before any complaint had been made, he sought out the visitor, explained the overcharge, returned the full amount of the money, and three days later dismissed the assistant. Two witnesses, moreover, came to say that they had benefited by this special scalp treatment. Sir Chartres Biron held that, even assuming that Mr. Caplan had been absent on the occasion in question, there was sufficient evidence that his establishment was not properly conducted. The appeal failed and the licence is revoked.

The public must be protected from bogus diagnosis of scalp disease and from gross overcharges in respect of it. Mr. Caplan may have been unfortunate in his assistant, but it is satisfactory to find that the vigilance of the General Purposes Committee of the L.C.C., and its prompt action in revoking the licence, found support and confirmation on a re-examination of the facts by an expert legal tribunal.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Aberdeen Hospital Development.

FOR several years the city of Aberdeen has been much exercised about the inadequacy and scattered nature of the existing hospital services. Under the inspiration of Prof. Matthew Hay a large scheme was put forward for uniting the various hospitals in one campus, and has had much support, but the difficulties have been enormous, and meanwhile the public health service of town and county must, like the King's Government, be "carried on." This is, no doubt, the meaning of the expansions now announced. The Aberdeen City Hospital is to undergo further enlargement at a total cost of nearly £70,000, the extensions including a new venereal disease ward and department, a new 60-bed ward, two 40-bed wards, and a new nurses' home. When the work is complete the hospital will have nearly 500 beds. This extension, however, is all in the day's work. What does present novel features of great significance is the arrangement now all but completed between the public health authority and the Poor-law authority. The town council, as public health authority, is to take over from the Poor-law the general and the special hospitals at Old Mill, which were opened in 1907 to provide for the medical work of the Poor-law authority. During the war those two fine hospitals were used for military purposes; but, owing to certain conditions, the Poor-law authorities found it impossible to make full use of the buildings, and were unable to persuade the General Nursing Council for Scotland to accept their training as qualifying for registration. This will now be at an end. The town council is to take over the buildings on condition that it provides for the full medical treatment of all the Poor-law patients for whom the parish council is responsible, and that it adapts the special hospital for the treatment of surgical tuberculosis, pneumonia, and other illnesses, both for the city and the neighbouring counties in the north-east of Scotland, in coöperation with the local authorities of those counties. These developments should result in the hospital being recognised as a training school for nurses and add greatly to its efficiency. It is at once a symptom of the growing demand for hospital treatment and of the need for bringing the Poor-law work on to the plane of modern medicine. Already in Scotland it has happened that a well-equipped Poor-law hospital has been placed in part at the disposal of voluntary hospitals or public health authorities; but this is the first time that a local authority has proposed to take over, lock, stock, and barrel, the full medical organisation of the

Poor-law and to do the work of the Poor-law as well as their own.

Analogies from the Eye.

The opening address of the winter session at the James Mackenzie Institute for Clinical Research, St. Andrews, was delivered on Oct. 5th by Dr. Maitland Ramsay, the hon. director. He pointed out that in the eye physiological and pathological processes can be directly observed as they occur in a state of nature, as distinguished from experiment under artificial conditions; since it is a fundamental principle that similar structures behave alike in all parts of the body, the phenomena observed in the eye are a valuable index of the conditions obtaining in other organs. With this in mind, he drew attention to analogies and contrasts between the non-striped muscle of the eye and that of the heart and other hollow viscera. The nerve-supply of the non-striped muscle of the eye is derived from the sympathetic on the one hand, and the cranio-autonomic on the other—the dilator muscles, whatever their position, having a sympathetic supply, while the constrictor muscles are innervated by the cranio-autonomic. These supplies are anatomically, as well as functionally, distinct. As a result of this reciprocal innervation the pupil is never at rest, the two opposing actions maintaining an equilibrium adjusted not only to the influence of light but to afferent impulses from all over the body. The pupil, for example, varies with respiration, while it contracts during cardiac systole and dilates during diastole. In the eye the dissociation of structures concerned in contraction and dilatation is so complete that a study of the reflexes of the pupil ought to throw light on the mechanism of the heart-beat and the peristalsis of the bowel. Speaking of the analogy between the nerve-supply of the iris and of the heart, Dr. Ramsay pointed out that sympathetic and cranio-autonomic nerves opposed one another in each instance; contraction of the pupil is analogous to slowing, and dilatation to quickening, of the heart. In their reaction to drugs the two organs show a similar analogy. Atropine dilates the pupil and quickens the heart by paralysing cranio-autonomic endings. Adrenalin produces similar effects by stimulating the sympathetic. Loss of the light reflex in Argyll Robertson pupil is no evidence of disease of the iris itself, any more than heart-block is evidence of disease of the ventricular muscle. The severe pain which accompanies spasm of the iris is comparable to that accompanying spasm of non-striped muscle elsewhere—in the heart, intestine, or ureter. The process underlying its production is in each case the same. The ciliary muscle and the heart muscle are two muscles of the body which can be overworked by an effort of will; in one instance the result is the pain and hyperalgesia of eyestrain, and in the other it is angina pectoris. Both can be restored by physiological rest. Each muscle hypertrophies when subjected to prolonged strain and both become, at the same time, more easily broken down.

On Oct. 12th Prof. J. A. MacWilliam read a paper on High Blood Pressure from the Physiological Aspect, before a large audience. An animated discussion followed.

Ices.

At a recent food exhibition, which was a trade affair, there was one very popular stall selling ice-cream. The novel feature about it was that the stall was run by a large dairy company. Obviously the trade in ice-cream is growing large enough to become a feature of the milk market. This trade is difficult to regulate, and it is interesting to speculate whether the fact that a large dairy company finds it worth while to establish such an exhibit means that the manufacture of ice-cream for the general market can be made to pay. Any physician knows that ice-cream, properly made, may be a very valuable nutrient and therapeutic agent, whilst of its popularity with all classes there can be no doubt. The meaning of such popularity is a social problem for the nutritionists. It may be that the excess appetite for this type of preparation is only a symptom of some deficiency in the normal diet. Anyhow, it is an interesting fact to observe that a general dairy company should make the commercial experiment.

Housing.

It is now possible to get a rough idea of the number of houses built in Scotland since 1919. Of houses actually completed, either by local authorities or by subsidised private enterprise, the number is approximately 44,000; the number under construction is about 20,000. A striking feature of the Scottish industrial landscape, say between Edinburgh and Glasgow, are the numerous groups of new houses visible either from road or railway. The comment on the groups of steel houses now appearing is that they look "very pretty." Time alone will tell what satisfaction they can give; but, at least in external appearance, they hold their own. What proportion of houses is due to unsubsidised private enterprise it is impossible to say, but, on the whole, it looks as if the housing shortage of Scotland is now being systematically overtaken. To judge by the official figures the monthly output seems to have reached an average of round about 1000. Large schemes of slum clearance have already been officially investigated and others are being studied.

The Midwifery Position.

The doubling of the training period for midwives has had a disturbing effect on the maternity hospitals. It appears that it is now almost impossible to get probationers. Both in the east and west of Scotland this has been felt so severely that the maternity hospitals have either reduced or abolished their fees for training.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Intracutaneous Vaccination.

AT a recent meeting of the Budapest Royal Medical Society Dr. Géza Petényi read a paper on intracutaneous vaccination against small-pox. When using the scarification method, he pointed out, it is advisable not to bandage the site of the vaccination, because evaporation is checked, the skin gets macerated under the bandage, and secondary vesicles appear. Complications may arise, such as erysipelas, sepsis, encephalitis, and generalised vaccinia, and vaccination is contra-indicated for all children who are not perfectly healthy; this applies equally to older infants suffering from mild alimentary disturbance. Serious trouble may be caused by the presence of eczematous and inflammatory skin diseases, and vaccination should also be postponed when there is any possibility of the child being infected with skin diseases by those around him. Intracutaneous vaccination, said Dr. Petényi, is much superior to scarification, and very probably in a few years will be adopted exclusively. The lymph obtained in phials needs to be diluted with sterile salt solution from 40 to 100 times, and of this dilute solution 0·1 c.cm. is injected into the skin of the forearm or thigh. It is advisable first to puncture subcutaneously and then, passing the needle under the skin for 1 or 2 cm., to push the point of the needle into the superficial layer. The point of the needle should not become visible on the surface of the skin or a regular vaccination vesicle will develop. After the needle has been withdrawn the site of puncture is painted with tincture of iodine. In the course of intracutaneous vaccination two phases are discerned: after 24–48 hours a small, purple solid papule arises, and between the tenth and fourteenth days a round or oval red infiltrate appears, reaching its maximum in three days and then beginning to recede. A small infiltration may remain for months. Fever is present only in the second phase, and even then is considerably less than when scarification is employed; all

symptoms due to the vaccination are mild in their course. Result is assured by the evolution of the second phase. Numerous control observations indicate that the immunity produced by the intracutaneous method is equal to that caused by scarification in both duration and intensity. The new method has the advantage that secondary infections, autoinoculation, and scar-formation are strikingly absent, and that the symptoms are milder. In the presence of an eczema, however, neither form of vaccination should be used. Dr. Petényi considers that it is a mistake to vaccinate infants, as is now done, between the fifth and twelfth months of life, since the rapidly growing organism is at this time especially sensible to insult. It must also be remembered that this is the time of weaning, when the resisting power of children is reduced, even if they seem to bear it well. A further argument against too early vaccination is that vaccine renders the organism allergic, not only to the vaccina and variola virus, but also, apparently, to other substances; it is a common experience to observe in children obstinately recurring strophulus, the commencement of which is coincident with vaccination. If the operation were done at a later period of life these inconvenient sequels would be milder and have a shorter course, if only because as time passes the tenderness of the skin decreases.

The Meinicke Micro-reaction for Syphilis.

At a recent meeting of Hungarian pædiatrists Dr. Ödon Kovács gave an account of his investigations into the Meinicke micro-reaction for the diagnosis of syphilis. Comparative tests, he said, were made in 520 cases. The Wassermann and the Meinicke reactions agreed in 461 cases (88·7 per cent.), and differed in 59 (11·3 per cent.), this ratio conforming to the results of other workers. Where they differed the Meinicke reaction was positive and the Wassermann negative in 9·2 per cent. of cases, whilst in 2·1 per cent. the Wassermann was positive and the Meinicke negative. The cases showing differences were almost all of them latent and treated cases. Out of 63 manifest cases of syphilis the Meinicke reaction was positive in 61, and the Wassermann reaction in 60. In 45 healthy infants under 6 months old Dr. Kovács did not get one single positive Meinicke reaction. As a result of his observations he regards the Meinicke reaction as more sensitive than the Wassermann, but he does not go so far as to say that it is of equal value in the diagnosis of syphilis; this can only be decided after several thousand tests have been made. For the time being he recommends that the Meinicke reaction be used only for orientation; if it prove positive, it should be corroborated by the Wassermann reaction. By this means it would be possible to make systematic blood tests in every single case in children's hospitals and save much time; the new reaction does not require the expensive laboratory equipment nor the services of a bacteriologist which would be needed if the Wassermann reaction had to be done in every case.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the statistics of three English county boroughs and one Scottish burgh for 1925:—

Name of town.	Estimated mid-year population (R.G.).	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.	
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Infant mortality.	Maternal mort. from childbirth.
Bradford ..	290,200	16·6	14·0	0·98	1·40	3·1	1·4	95	3·7
Portsmouth..	232,900	19·1	12·3	1·09	1·39	2·0	1·4	62	2·5
Oldham ..	146,200	15·5	14·8	1·02	1·37	3·4	1·6	103	6·1*
Paisley.. ..	85,960	22·5	13·2	1·34	1·20	2·5	1·5	96	6·7

* Of the 14 deaths contributing to this rate 9 were from "abortion, miscarriage."

Bradford.

Dr. John J. Buchan says that the hospital accommodation available for Bradford amounts to more than 3500 beds—about one bed for 80 of the population. Only one of the sources of the water-supply is plumbo-solvent—namely, that from the peaty uplands of Thornton Moor. This water has been treated for the last five years by the addition of calcium carbonate and subsequent filtration through slow sand filters, with the result that the amount of lead present in the water, when drawn before 8 A.M., is almost nil. The scheme for the conversion of privies makes progress, the number having been reduced from 10,367 in 1920 to 2612 in 1925. In 954 observations of industrial smoke, 141 chimneys were found to be transgressing the limit or on the verge of doing so. The causes of the excessive smoke were ascertained and the persons responsible were advised. In one case proceedings were taken for dense smoke emitted for 37 minutes during one hour. The defendant alleged that the smoke was not dense and the case was dismissed. Acting on the advice of the stipendiary magistrate, the smoke inspector has cautioned the responsible person and made subsequent observations of the chimney. This method has not proved effective, and Dr. Buchan regrets that such an appeal to reason meets with so little response. The cow population of the city was 3441 in 266 dairy farms. The total quantity of milk consumed is about 14,500 gallons daily, or less than half a pint per head. In the city 7500 gallons are produced, the remainder coming from outside by rail or road. Among the city cows 32 cases of tuberculosis were discovered; in 24 the udder was affected, and in 8 the disease was in an advanced stage. Ten of the cows were slaughtered by the owners, and 11 were taken away from the city and lost sight of. The introduction of the Tuberculosis Order on Sept. 1st enabled 11 to be dealt with, the compensation paid being £101. The Order will, it is hoped, henceforward secure that dangerous tuberculous cows are dealt with in a satisfactory way. Of the 126 samples of milk taken in the course of delivery to the consumer 7 were found to contain tubercle bacilli. The mortality-rate from pulmonary tuberculosis has shown a steady decline during the past ten years, and the same may be said of non-pulmonary tuberculosis, the death-rate for each type in 1925 being the lowest on record. The average rates from all tuberculosis in Bradford during the last five quinquennia have been 1·84, 1·65, 1·53, 1·46, and 1·05. The tuberculosis officer, Dr. H. Vallow, reports that patients taught new occupations at the training colonies have been unable to earn a living in the open market, and that the housing conditions of Bradford render the supply of shelters impracticable. From April 1st, 1917, until April 1st, 1925, the venereal diseases centre was carried on at the Bradford Royal Infirmary, but as the board of management could not spare the necessary accommodation any longer the centre has been moved to the municipal (St. Luke's) hospital, where adequate accommodation, with beds for indoor treatment, has been provided. Dr. Buchan thinks that the "private and confidential" conditions prevent adequate coöperation with the medical profession in carrying on the scheme, and that venereal disease could be better prevented from spreading if local authorities were empowered to obtain knowledge of infectious cases and insist on adequate treatment.

Figures show that the neonatal death-rate is declining although the improvement is small. More interest, however, is taken by women in the hygiene of pregnancy, and the fall in the mortality of early infancy will become more marked as knowledge is disseminated. In Bradford the midwives attended 76·9 per cent. of the registered births and sent for medical help in 13·5 per cent. of their cases. The total number of patients attending the antenatal centres was 489—just over 10 per cent. of the total births. The medical profession is paying more attention to this subject, says Dr. Buchan, but improvement in the attendances can only result from an increased desire amongst women for skilled supervision.

The number of new houses certified in 1925 was the highest for any one year in the records of the city—namely, 1509; of these 947 were municipal. The number of municipal houses under contract at the end of the year was 1281—1059 of the "A" type, 70 of the "A 2" type, and 152 of the "B" type. In addition to these there were 526 houses, mostly of a superior type, under private construction. In spite of this improvement, many very serious cases of overcrowding could not be dealt with owing to the scarcity of houses. At the close of the year the applicants for new houses numbered 4168, and of these 2715 were ex-Service men, 1617 of whom were living in apartments.

The diagram in the school report shows that Bradford provides every kind of special school. The outstanding feature of the dental work is the increased demand for treatment, which has resulted in the curtailment of the time given to inspection by the four dental surgeons. The work of the ophthalmic surgeon, Dr. W. Oliver Lodge, emphasises the importance of examining the eyes of young infants. More children at the pre-school age are coming under observation, and it is suggested that systematic examinations in infancy will in time secure the development of binocular vision endangered by errors of refraction, will prevent permanent squint, will enable myopia to be dealt with at the most favourable time, will prevent the onset of nystagmus, and will be helpful in the treatment of many other diseases of the eye. A complete scheme is now in operation for cases requiring orthopædic treatment, and Mr. F. W. Goyder is in charge of all such cases at the orthopædic clinic at St. Luke's Hospital, the Lister Lane School for physically defectives, and the surgical tuberculosis wards at Grassington Sanatorium. Children at Grassington requiring operation are transferred to St. Luke's, where a balcony has been put up for open-air treatment and artificial sunlight has been installed. Treatment may last three years, and when the disease has been arrested the children are transferred to Lister Lane School, where their subsequent progress can be watched.

Portsmouth.

Dr. A. Mearns Fraser, in his thirtieth report, tells us that, apart from the dockyard, one of the principal trades is stay-making, in which 1938 women are engaged. The building trades employ 3700, commerce nearly 11,000, and domestic service 10,200 women, whilst the military population averages 20,000. Southsea, the residential part of the town, has a reputation as a health resort from its mild winters and its sunshine record. During 1925 it came out third of the meteorological stations with 1923 hours of bright sunshine. Southsea common, with its 112 acres fronting the sea, was acquired by the corporation during the year.

Only 6 per cent. of the babies die in their first year of life, compared with 16 per cent. 30 years ago. During May an outbreak of scarlet fever affecting 63 persons was traced to ice-cream. This was made by a dairy company at one of its branches only and customers for milk from other branches were not affected. The infecting agent was apparently a boy who helped to make the ice-cream and who went on working up to the day the rash appeared, in spite of a sore-throat which he did not mention for fear of losing his work. One of the features of the outbreak was the short incubation period—a feature which has been noted by other observers in the case of milk epidemics. There were 47 cases of enteric fever with five deaths. Thirty years ago there were seldom less than 300 in the year and in 1900 there were over 1000 cases. Dr. Fraser is sure that the present number would be reduced if people could be persuaded not to eat shell-fish picked up on the seashore near the town. The case-fatality of encephalitis lethargica was high; out of 17 known cases there were nine deaths. Tuberculin is reported to give favourable results in eye affections and for glands and genito-urinary tuberculosis, and injections of collosol calcium have been found beneficial in a few cases, especially those with hæmoptysis. At the venereal diseases clinics irrigation facilities for gonorrhœa are provided daily, including Sundays, for men and women. The number of new cases at the clinics has averaged about 200 each year since 1917, except for the years 1919 and 1920, when the figures reached 342 and 319. The 50 beds at the Treloar Hospital, Alton, reserved for Portsmouth crippled children, have now been supplemented by five beds at Hayling Island. At the municipal maternity home 219 women were confined with one death. The antenatal clinic, conducted at the home, was attended by 589 patients. Plans have been drawn up for a new maternity home and child welfare centre combined. The Royal Naval Maternity Home makes provision for the families of men in the navy and marines, and during the year admitted 273 cases for confinement and conducted antenatal and child welfare clinics. About 65 per cent. of the total births were attended by midwives, who sent for medical help in some 27 per cent. of their cases. The collecting grounds of the town's water-supply are probably the northern downs of Hampshire, and attention is drawn to the possible contamination of this area by the erection upon it of numerous cottages and bungalows without proper drainage or means of refuse disposal. Overcrowding is still serious, and Dr. Fraser is of opinion that the facilities for persons with a very little capital to build for themselves under the Housing Act of 1925 are not enough known, and that the estate acquired by the council on Portsdown Hill is being insufficiently used for building purposes.

The public analyst's report shows that four out of 34 samples of Certified Milk, two out of 12 samples of Grade A (tuberculin tested), and five out of 53 of Grade A failed to pass the tests for their respective grades. The average retail prices of these three milks were 1*s.* 2*d.*, 8*d.*, and 7*d.* per quart respectively.

Oldham.

Dr. James B. Wilkinson says that the chief event of the year was the opening of the hospital part of Strinesdale Sanatorium. Ultimately there will be 56 beds for patients; at present, till the administrative part is renovated, there are only 42 beds. The patients are divided into two classes according as the sputum is positive or negative, and these are housed in separate parts of the building. Children are kept apart from adults and there are observation wards of one and two beds. A view of the new building forms a frontispiece to the report. Dr. Wilkinson shows how Oldham suffers from the smoke of its neighbours on the lower levels to the south-west, south, and south-east. He also points out that the permissible Oldham limit for its own smoke is a liberal one—viz., two minutes in the half hour for a chimney serving two boilers, three minutes for three boilers, and four minutes in the half hour for four or more boilers. He feels strongly that no great improvement will take place in the Oldham atmosphere till the endeavours made to form a smoke prevention district for south-east Lancashire are successful. The chief occupation is cotton-spinning, for which the damp climate is said to be favourable, as, it makes the fibres less liable to break. There are also two large firms making cotton machinery, which employ 20,000 people when working full time, and two coal-mines. The trades are not inimical to health, but there are a few cases

of spinners' cancer attributed to oil irritation, Dr. Wilkinson states, and careless exposure to the cold and damp atmosphere after working in hot mills may be responsible for some cardiac and pulmonary illness.

There are no maternity beds available except in the Poor-law hospital, and a scheme is on foot for acquiring a large house for a maternity home with a babies' hospital to be erected in the grounds. During the last five years the number of untrained midwives have fallen from 12 to three. During the past three winters series of lectures by consultants from Manchester and Liverpool and other places have been arranged for the midwives.

Formerly it was the practice for thrifty people to join building clubs and so erect their own houses, but lately the building of houses for the working class has been relegated to the council, although, Dr. Wilkinson says, there are still ample facilities for those with a few pounds in hand to build either through the coöperative stores or one of the remaining housing companies. There is a considerable shortage of houses and much moral, if not technical overcrowding, and a difficulty in getting unfit houses renovated owing to bad trade and the financial position of small owners of property.

Paisley.

Dr. G. V. T. McMichael points out that the Infectious Diseases Hospital is an old building requiring heavy expenditure on repairs and designed to deal with only three diseases; the erection of a modern fever hospital on the outskirts of the town must soon be faced. He lays emphasis on the value of hospital treatment of pneumonia, especially in view of present housing and economic conditions. Of 345 cases of acute primary and influenzal pneumonia 70 per cent. were admitted to hospital. The mortality at the Fever Hospital was 15·8 per cent., and at the Royal Alexandra Infirmary 16·4 per cent.; the mortality at home was 38·4 per cent. There were 44 notifications of ophthalmia neonatorum, mostly mild, but including six serious cases of gonococcal origin. One case, in which there was serious impairment of vision, was the subject of inquiry by the Scottish Board of Health. The other serious cases were referred at once to the Eye Infirmary, but this one was treated at home by the practitioner in whose practice it occurred, and was the first case of serious impairment of vision which has occurred in Paisley since 1918. The attendances at the antenatal clinic show an increase, and more of the mothers, especially the younger ones, ask for a complete examination early in pregnancy. The new cases numbered 255, more than one-eighth of the 1935 total births. The percentage of new babies brought to the centres whose weight was below normal was higher than in previous years, and this may be the result of the deplorable economic conditions. On the other hand, the cases of rickets numbered only 119, as compared with 180 in 1924. The number of antenatal cases admitted to the Barshaw Maternity Hospital was 168 and the number of confinements 333, the corresponding figures for 1924 being 124 and 296. Hospital treatment for diseases of pregnancy is always available at Barshaw, and this fact helps to promote the success of the antenatal work. There is a lack of accommodation for early cases of pulmonary tuberculosis and also for surgical tuberculosis in children, and a scheme is on foot to put up a county sanatorium of 110 beds at a cost of £76,000, which, it is hoped, will make good these deficiencies. Dr. Hugh C. Donald, of the venereal diseases clinic, reports striking results from the treatment of syphilis in women during pregnancy.

Progress is being made in housing, and Dr. McMichael is enthusiastic about the last two estates acquired by the council, on which it is proposed to erect 849 houses. The three municipal hospitals are supplied with Certified Milk, and about 16 gallons of this milk is retailed in the town. About one-third of the daily milk-supply is pasteurised and bottled at the Coöperative Creamery.

SCHOOL MEDICAL SERVICE.

Name of county.	No. on roll.	Av. elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.‡
Hertfordshire ..	39,888	—*	14,055	—†	20·1
Northamptonshire ..	26,906	—*	7,940	2,508	24·6
Lincolnshire: Holland ..	11,130	9,635	2,997	1,686	14·0

* Not given. † No reinspections; 60 specials.
‡ Excluding dental defects and uncleanliness.

Hertfordshire.

Dr. H. Hyslop Thomson sums up the work of medical inspection which is carried out by 20 assistant school medical officers who are, for the most part, medical officers of health of their localities. This arrangement is in some ways advantageous, but unless a clear policy is laid down and close coöperation maintained among the assistants, the results of local inspection tend to be unequal. In this case, among other things, the various methods adopted locally for the prevention of the spread of infectious disease and for closure of schools appear to lack coördination, and the fact that no reinspections have taken place indicates that the system for following up cases cannot be altogether satisfactory. Arrangements are made by the county for treatment of tonsils and adenoids at local hospitals and for defective vision by local ophthalmologists, while an orthopædic scheme is now in active being. Only two minor ailment clinics exist in the county, most of this work being carried out by the district nurses. At present there is apparently only one dentist employed, but further dental aid is contemplated. No definite provision is made for mentally defective children, though the county runs an excellent residential school for the feeble-minded, and Dr. Thomson reports fully on the conduct and progress of this institution. In an inquiry on rural children who walk a long way to school and stay there for the midday meal, Dr. Thomson concludes that these children, while thinner than those who live near the school, are healthier and more resistant to catarrhs and infectious disease. He insists, however, on the necessity for ensuring that these children have their school meal in comfort.

Northamptonshire.

Dr. Charles E. Paget remarks on the increasing interest of teachers and parents in the school medical work, as shown by the presence of 69·6 per cent. of the parents at the inspections. Teachers weigh and measure the children, test their eyesight by Snellen type prior to the medical officer's visit, and report to the S.M.O. the steps taken by the parents to secure treatment. Arrangements are rapidly being made, varying in individual schools, for drying rural children's clothes, for supplying dry slippers and socks, and for providing warmth, shelter, and hot drinks for those children who have their midday meal in school. The council make no definite provision for treatment of tonsils and adenoids or for treatment of ear and external eye conditions. Minor ailment clinics are in being at Wellingborough and Rushden, otherwise this treatment is given by the district nurses. No mention is made of open-air classes or schools, and there is no special provision for mentally or physically defective children, and no supervision of the feeble-minded who are not attending school. Dr. Paget finds that 141 mentally defective and 108 crippled children are in attendance at elementary schools. A scheme for orthopædic treatment is now before the council.

Lincolnshire: Holland.

Dr. H. C. Jennings reports that medical inspection in the secondary schools has been undertaken for

the first time this year. The sanitary condition of town schools in the district is much better than that in the country areas, but even allowing for special conditions which exist in rural localities, much needs to be done if these schools are to be rendered structurally and hygienically sound. Dr. Jennings holds that no child under 7 years of age should be expected to read from books and that from 7 years onwards uniform standards of types, of which he gives specimens, should be used. A scheme for dental treatment, including a dental van, was to be in full operation in the early part of 1926. Minor ailment clinics are held in six of the most important schools, and the following up work is carried on by nurses. The treatment of visual defects is in the hands of a consultant ophthalmologist, but no arrangements are made by the council for treatment of tonsils and adenoids, nor is special provision made for mentally or physically defective children.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 9TH, 1926.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox 121 (last week 96); scarlet fever, 1851; diphtheria, 1186; enteric fever, 91; pneumonia, 634; puerperal fever, 55; puerperal pyrexia, 180; cerebro-spinal fever, 4; acute poliomyelitis, 46; acute polio-encephalitis, 5; encephalitis lethargica, 33; dysentery, 17; ophthalmia neonatorum, 141. There were no cases of cholera, plague, or typhus fever notified during the week. Only one case of small-pox was reported from the London area, the remainder, as before, from the counties of Derby, Durham, Lancaster (Ashton-in-Makerfield), Northumberland, Nottingham (one only), and Yorks, West Riding.

Deaths.—In the aggregate of great towns, including London, there was 1 (1) death from small-pox, 5 (0) from enteric fever, 6 (0) from measles, 3 (1) from scarlet fever, 22 (4) from whooping-cough, 36 (8) from diphtheria, 221 (49) from diarrhœa and enteritis under 2 years, and 36 (11) from influenza. The figures in parentheses are those for London itself. The small-pox death was of a case belonging to the Metropolitan Borough of Lambeth.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. Comdr. O. D. Brownfield to be Surg. Comdr.

ROYAL ARMY MEDICAL CORPS.

Col. C. J. O'Gorman, late R.A.M.C., retires on retd. pay.

Lt.-Col. and Bt. Col. H. H. Norman, from R.A.M.C., to be Col.

Maj. M. F. Grant to be Lt.-Col.

Capts. D. G. Cheyne, P. A. Opie, S. Fenwick, G. W. Will, and D. C. Scott (Prov.) to be Majs.

Lt. (on prob.) H. McVicker, from the secd. list, is restd. to the estabt.

2nd Lt. R. A. M. Humphrey, from the Gen. List, Aberdeen Univ., O.T.C., to be Temp. Lt.

TERRITORIAL ARMY.

Capt. R. Errington to be Lt.-Col. and to command the 149th (Northumbrian) Field Amb.

Capts. J. A. C. Scott and A. C. M. Savege to be Majs.

Capt. (Prov.) E. R. Woodroofe is confirmed in his rank.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. J. W. Craven, from the Active List, to be Lt.-Col.

ROYAL AIR FORCE.

Squadron Leader B. F. Beatson is placed on the retired list at his own request.

Flight Lt. H. R. Peek (temp. Capt. Army, Dental Surgeon) relinquishes his temporary commission on return to Army duty.

INDIAN MEDICAL SERVICES.

Majs. B. E. M. Newland, O. A. R. Berkeley-Hill, W. L. Harnett, J. D. Sandes, A. H. Napier, G. Holroyd, D. L. Graham, E. B. Munro, J. A. S. Phillips, P. M. Rennie, and H. M. Inman to be Lt.-Cols.

Capts. J. B. de W. Molony, H. G. Alexander, Kanshi Ram Batra, Bawa Harkishan Singh, Pindi Dass Chopra, A. H. Harty, G. Shanks, and R. L. Vance to be Majs.

"Audi alteram partem."

PASTEURISATION OF MILK.

To the Editor of THE LANCET.

SIR,—I thank your correspondents who have taken an interest in my letter of August 14th. The question may be brought roughly under three headings:—

(1) *Is general pasteurisation in the interest of the consumer?*—My contention is that pasteurisation as usually carried out is used to the advantage of the dairyman rather than of the consumer, and to support this view I stated that a dairy manager had informed me that he keeps pasteurised milk as long as 36 hours in his shop before sale and that this would be impossible if the milk were not pasteurised. On Sept. 30th I asked my wife to order an extra pint of fresh milk and one of pasteurised to be delivered early on the morning of Oct. 1st. These were kept for a matter of five and a half hours from 6.30 A.M. to noon, at a temperature rising from about 40° to 60° F., before a bacteriologist made counts on the samples. The results of the bacterial counts were as follows:—

Raw milk	100,000 per c.cm.
Pasteurised milk	3,450,000 ,,

Both samples contained gelatin-liquefying bacteria, the pasteurised being worse than the raw milk; it was hardly necessary under these circumstances to test for the colon bacillus. By 3 P.M. a colleague remarked to me that the pasteurised milk was beginning to smell sour, and it curdled long before the sample of raw milk.

In order to check these results on Oct. 6th I obtained further samples of fresh and pasteurised milk. After keeping for eight hours these gave the following bacterial counts:—

Raw milk	60,000 per c.cm.
Pasteurised milk	1,000,000 ,,

Both samples contained the colon bacillus. The fresh milk contained no preservatives.

I take it that Dr. Moore had his sample tested to find out that it was raw milk and not pasteurised, since I can assure him that most samples of milk purchased in the streets of London are pasteurised. I cannot agree with him that the presence of the colon bacillus denotes contamination with cow dung; it is suspicious and I should think, from my experience, that most samples of raw milk collected from country farms would contain it, but the streets are full of this bacillus and most milk delivered from a milk-can at street doors contains them.

As regards the safety of milk which has been pasteurised commercially Dr. C. G. Grulee, of Chicago, states ("Infant Feeding") that commercial low temperature pasteurisation is often carried out on bad milk and that the time of delivery after heating is so long that bacterial growth is very great. Magee and Harvey, of the Rowett Research Institute, Aberdeen,[1] state that pasteurisation improves low-grade cow's milk and makes it a marketable product for many hours after being milked, but it should be noticed that they specify hours and not prolonged keeping in a shop. If Dr. Moore had taken my two sentences together he would have read me as stating: "Pasteurised milk may go bad without curdling, if kept for any length of time. Curdling is still looked on as the signal of milk going bad . . ." and I added that the former sentence was not only an expression of my own experience, but also that of a dairy manager.

Dr. Moore calls my attention to the work of Ayers and Johnson, but the still more recent work of Prof. Orla-Jensen[2] shows that lactic acid bacteria, which survive low temperature pasteurisation, only grow slowly at low temperatures and that the milk so treated may eventually become worse if treated by high temperature pasteurisation. Prof. Orla-Jensen is professor of biochemistry in the Polytechnic

[1] Biochem. Jour., 1926, xx., 873.
[2] Dairy Bacteriology, translated by Arup, 1921, p. 85.

College, Copenhagen, and was formerly Director of the Swiss Experimental Dairy Station, and his translator is chief chemist to the English Margarine Works. As to the necessity for pasteurisation, it is well to remember that, a year or two ago, we were informed that dairymen and others could not comply with the report of the Departmental Committee on preservatives in cream and other articles of food, but they seem to be managing to toe the line. In many of the large American towns the standards for ordinary raw milk are 500,000 per c.cm. or even less, and it should be possible to emulate this standard generally in our country.

(2) *If pasteurised milk is to be sold ought not the public to be educated as to the difference between pasteurised and raw milk, or any other grade of milk?*—Even where people observe a small disc at the top of the bottle with the word "pasteurised" among a lot of other information, do they know or take the trouble to find out what it means? Prof. Kenwood, who is, I believe, a public analyst, inquires what the local health authorities are doing if dairymen do not know the difference between various grades of milk. Has he systematically been through his borough to find out whether they do? If he has, I think he is exceptional. I was told a few days ago by a shopkeeper that she stocks sterilised milk only, because it is simpler and also because her wholesaler, a sterilised milk company, informed her that sterilised milk was safest. Incidentally it may be of interest to know that the common test, to find out whether sterilised milk is good or bad, is to hit the bottom of the bottle before opening; if there is a hollow sound the milk is good, if not the milk is bad.

(3) *Is pasteurised milk equal to raw milk in quality?*—Dr. Moore says that it is not. I have to thank him for giving me, privately, the reference to Prof. Pierre Budin's statement concerning the antiscorbutic properties of sterilised milk. I would point out that this statement was made before the subject of vitamins was properly understood, and in connexion with such work Barnes and Hume[3] draw attention to the fact that it is never stated definitely whether all antiscorbutics have been excluded, while Dr. Grulee notes that as far as possible Budin used "wet-nurses." If we consult Budin's work, "The Nursling" (translated by Maloney), we find (p. 27) that for weakly infants the milk is made to trickle into their mouths directly from the nipple by exerting pressure upon it; (p. 50) that when an infant is born weakly it is either (*a*) entrusted to a wet-nurse, or (*b*) nourished by the mother herself; (p. 122) Budin explains his system of mixed feeding and comments on the fact that he was at first condemned by his medical colleagues for adopting such a course.

In the light of modern research it is obvious that Budin's belief in the antiscorbutic properties of sterilised milk cannot be accepted, though it is fair to note that he sterilised his milk under such conditions that air was excluded, and laid it down that the sterilised milk was only to be warmed in the bottles in which it had been sterilised before use. Prof. Plimmer has shown that re-heated pasteurised milk contains no antiscorbutic properties.

In reply to the question why, if we cook bread, vegetables, meat, &c., we may not cook milk, may I, with all respect, ask whether it is the custom to buy cabbage cooked or to cook it at home? The chief point I made in my former letter was that milk is largely used for the preparation of infants' foods in the home, and as such is cooked in the process. Nobody advocates the consistent double-cooking of their own food; why should we double-cook an infant's food?

Those interested in the feeding properties of pasteurised milk as compared with raw milk should refer to the valuable papers of Daniels and Stearn[4] and Magee and Harvey.[1]

I am, Sir, yours faithfully,

Oct. 9th, 1926. THOMAS MCLACHLAN.

HÆMORRHAGE ASSOCIATED WITH PERITONSILLAR ABSCESS.

To the Editor of THE LANCET.

SIR,—In your correspondence columns on July 17th (p. 149) Mr. A. J. Wright reported a case of severe hæmorrhage following spontaneous rupture of a peritonsillar abscess which he treated by dissecting out the tonsil and stitching up the fossa. I have for many years adopted this procedure in every case of peritonsillitis, slight or advanced, and have been uniformly pleased with results. I began by lifting off the anterior pillar to allow pus to escape in place of the usual incision. I then proceeded to finish the dissecting out of the tonsil, and for ten years have adopted this method for all enucleation cases. I use an elevator like the one figured in D. McKenzie's book. Where adhesions are very strong I use a long pair of slender scissors curved on the flat. For grasping the tonsil, nothing is so satisfactory as a blunt guillotine. I only resort to a volsellum for the preliminary stage when I cannot engage the tonsil with a guillotine.

In 34 years I have had only three cases of severe hæmorrhage, one in a child at the Children's Hospital, "primary," and overcome with artery forceps; one in a young adult at the Melbourne Hospital, a "partial" hæmophiliac, which gave us anxiety for months, and one in private, which occurred in an adult female, 36 years, which was also stopped with artery forceps. I had one death 30 years ago from inhalation of large blood clot, and I attributed it to the head dorsi-flexed position plus chloroform anæsthesia; a second death from ethyl chloride anæsthesia in a gross case of congenital syphilis; and a third in a case of peritonsillar abscess with septic laryngitis. This last case was a desperate one and occurred in a medical colleague.

I never use ligatures of any kind except in those rare instances where the posterior pillar has been badly torn or cut. I have no record of number of cases, but besides a large private practice I have been surgeon to four hospitals in Melbourne, and for some years did 40–50 cases a week, so I consider I must have done 30,000 cases at least.

I am, Sir, yours faithfully,

W. KENT HUGHES, M.B. Lond.,
Late Surgeon to Children's Hospital, Melbourne, and Clinical Surgeon to Melbourne Hospital,
St. Vincent's Hospital, and Metropolitan Mission, Melbourne.

Sept. 10th, 1926.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

To the Editor of THE LANCET.

SIR,—As there seems to be some misapprehension in the public mind as to the future policy of this hospital, I should like to explain that although the site and buildings have been sold to our next-door neighbours, the work of this institution has *not* been absorbed or taken over by Charing Cross Hospital. Owing to lack of accommodation, and the increasing demands upon its resources, this old and useful eye hospital, founded 110 years ago, is removing to a new freehold site which has been purchased by the governing body in Broad-street, W.C.2, upon which will be erected one of the finest and most up-to-date institutions of its kind in the kingdom. Tenders for construction of the new building will be received shortly, and it is hoped to commence building operations before the end of the year. In conclusion, I might add that one of the conditions of sale to Charing Cross Hospital was that possession would not be given until the new building is ready for occupation, so that our work of treating sufferers from injuries or diseases of the eye can be transferred to the new hospital without closing for a day. This transfer is expected to take place about the end of March, 1928.—I am, Sir, yours faithfully,

JOHN H. JOHNSON,
Secretary, Royal Westminster Ophthalmic Hospital, King William-street, West Strand, W.C. 2.

Oct. 14th.

PRINCIPALS AND LOCUM TENENTS.

To the Editor of THE LANCET.

SIR,—Some misunderstanding appears to exist with regard to the protection which the two English defence societies afford their members when threatened with proceedings owing to the acts of locum tenents. The Council of the Medical Defence Union passed the following resolution on Jan. 21st, 1926 :—

"That from and after the date of this resolution the Council may in its discretion assume responsibility for any claim made upon a member in respect of the act or omission of any registered medical practitioner, whilst temporarily employed as locum tenens for such member."

The Council of the London and Counties Medical Protection Society passed an identical resolution, and the position of the two societies in this respect is precisely the same.—We are, Sir, yours faithfully,

HUGH WOODS,
General Secretary, London and Counties Medical Protection Society, Ltd., Victory House, Leicester-square, W.C.

JAMES NEAL,
General Secretary, Medical Defence Union, Ltd., 49, Bedford-square, W.C.

Oct. 13th, 1926.

MENDELIAN VARIATION IN BACTERIA.

To the Editor of THE LANCET.

SIR,—Your annotation of Sept. 25th (p. 660) with this title raises four points which call for reply.

(1) You write: "Technically such experiments ought to begin with a single cell isolated with all the certainty which is available. Dr. Stewart seems to have taken no particular precautions about the purity of his cultures."

Burri's single cell culture to which you refer has been extensively tried in this class of research. Bernhardt [1] reports on it as follows: While we used Burri's single cell culture for the confirmation of our results in our first experiments on dysentery bacteria, we have at a later stage satisfied ourselves in agreement with the other workers, that we could achieve the same results by the usual methods of bacteriology (efficient dilution of the initial material, laying out a series of plates). We have, therefore, abandoned Burri's method, which is tiresome, a waste of time, and not always applicable. My technique has consisted of the usual methods of bacteriology outlined in this quotation.

(2) You write: "It is also necessary to assume non-viable recessives . . . . if mutabile on ordinary media is really a heterozygote."

But my argument is that mutabile will not segregate without the stimulus of the specific sugar, and therefore this assumption is not necessary.[2]

(3) Variations of the colon typhoid bacteria "have been discussed as examples of mutations, adaptive variations, acquired heritable characters . . . . Dr. Stewart gives another explanation."

I, on the contrary, consider Mendelian variation and mutation to be the same as adaptive variation and acquired heritable characters, all four arising from segregation of allelomorphs. The type of segregation studied in bacteria, which is best called restricted segregation, I consider to be related to gametic segregation in the following manner. In restricted segregation a single sharp-pointed external stimulus (e.g., lactose) impinges on one pair of allelomorphs only, and causes that pair alone to segregate in adaptation to the stimulus. In gametic segregation, on the other hand, a complex mass of external stimuli bears on the germ-cells, and causes segregation of many, if not of all, the allelomorphs. This mass of external stimuli consists of the hormones of the parent in their adult condition (senility in protozoa, see Calkins and Woodruff). Gametic segregation is possibly also adaptive and represents the reaction of the germ-cells to the maturity (senility) of the parent, reaction and adaptation being equal and opposite. Examples of restricted (= somatic) segregation are to be found not only in bacterial variation, but also in bud variation in higher plants and probably in acquired immunity to some diseases in higher animals, and in non-parasitic tumours.

(4) You write: "The theory as a whole rests on a slender basis, it postulates somatic segregation . . . . the production of recessive mutations by environment . . . . and non-viable dominants."

For a good example of somatic segregation in higher plants see the case of mosaic seed capsules in the hybrid between *Datura stramonium* and *D. lævis*.[3] *Non-viable dominants.*—Since writing the paper under review I have on one occasion found a homozygous dominant, paracolon, in subculture from a thoroughly purified heterozygote, mutabile.

I have almost completed a paper which elaborates and continues the subject under review.

I am, Sir, yours faithfully,

F. H. STEWART,
Major, I.M.S. (retd.).

Edinburgh, Oct. 11th, 1926.

*** It is obviously impossible to discuss briefly whether Dr. Stewart is right in considering Mendelian variation and mutation to be the same as adaptive variation and acquired heritable characters. In that proposition he raises one of the great biological problems, and we hope that his further researches will convince everyone that he has solved it.—ED. L.

THE RELATION BETWEEN CANCER AND TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—In the annotation on this subject in your issue of Oct. 16th it is stated that Dr. T. Cherry, of Melbourne, recalled an observation made by Mr. W. R. Williams that when several members of a family had died of phthisis the survivors were very apt to die of cancer. As an insurance medical officer of several years' experience, and one who has had, therefore, great opportunities of studying many family histories, I have been frequently struck—prior to Mr. Williams's observation—by the concurrence of these two complaints in members of families at different ages. I have questioned whether the explanation is to be found in the fact of a mere coincidence or of the different age incidence of the two diseases, or whether possibly there is some deep real connexion between the two. As Mr. Williams stated, a further inquiry is needed.

I am, Sir, yours faithfully,

ARTHUR T. DAVIES,
Chief Medical Officer to the North British and Mercantile Insurance Co.

Oct. 18th, 1926.

EOSINOPHILIA AND ACIDOSIS.

To the Editor of THE LANCET.

SIR,—When views are imputed to an author by a misunderstanding of his book there is excuse to take note. In a notice of my book on Asthma (THE LANCET, Sept. 25th, p. 654) your reviewer says: "When the author discusses theory he often becomes too hypothetical, as when he suggests that the large number of eosinophil cells are present in asthma in order to absorb acid and so preserve the alkalinity of the blood." I did not suggest that these cells are present *in order to* absorb acid, but I did suggest that their presence in such number might be the *result* of the chloride shift known to occur in cases of acidosis. So far as I am aware no other explanation of eosinophilia has been given; at any rate, it is a feasible explanation and fits the case, for the degree of eosinophilia is in proportion to the persistence of the asthma and is an excellent guide to prognosis. I admit, however, that I am not conversant with the

[3] Darwin: Animals and Plants under Domestication, i., 392; and Bateson: Mendel's Principles.

relationship of acidosis to eosinophilia in diseased states other than asthma and characterised by eosinophilia. Certainly eosinophilia does not characterise epilepsy which Cuneo claims to be an acidosis, which, like him, I have known to be produced by faulty diet and hygiene similar to those which produce asthma, and which I have cured by *early* attention to those errors.

To one other point I may be permitted to refer. Your reviewer says that another writer asserts removal of polypi may make asthma worse. For a quarter of a century I have been removing polypi in cases of asthma and have never seen a case that was not benefited. Where a case seems to have been made worse your reviewer may be quite sure that it was not efficient operation that made the asthma worse. Efficient operation is often not easy and post hoc is not propter hoc. Greater folly than leaving polypi untreated in asthmatics it would be hard to conceive, but it may be a product of the present craze about anaphylaxis.

I am, Sir, yours faithfully,

Glasgow, Oct. 9th, 1926. JAMES ADAM.

*** The reviewer, while believing that he has nowhere misunderstood Dr. Adam, says that any suggestion on his part of a teleological cause for the phenomena was accidental.—ED. L.

ANÆSTHETICS IN UROLOGY.

To the Editor of THE LANCET.

SIR,—In the October issue of the proceedings of the Royal Society of Medicine, under the discussion on anæsthetics in urology, Dr. F. E. Shipway mentioned that "one of the anæsthetists at St. Peter's Hospital, being a Scotchman and not converted to modern methods, still used chloroform for his cases, and the resident medical officers had told the speaker (Dr. F. E. Shipway) that there was a distinct tendency to uræmia on the part of those patients, as compared with those who received spinal anæsthesia." I cannot compliment Dr. Shipway on the manner in which he refers to his colleagues at St. Peter's, but if it is a modern method of comparing his particular scientific work to that of others, I am content to remain old-fashioned. After remarking on the "tendency to uræmia" in the patients given chloroform, he says that those given ether tend towards bronchitis. Surely this is comparable to the layman's phrase, "a tendency to consumption." It would be interesting to know where the tendency ceases and the disease begins. Possibly Dr. Shipway has a tendency to exaggerate the importance of spinal anæsthesia in urinary surgery.

I am, Sir, yours faithfully,

Oct. 18th, 1926. J. D. SPEID SINCLAIR.

Obituary.

HENRY PORTER D'ARCY BENSON, M.D., F.R.C.P., F.R.C.S. EDIN.

NEWS has reached this country of the death of Dr. D'Arcy Benson at Kimberley on Oct. 6th. He had spent the last few years in South Africa because poor health prevented him working in the British Isles. Dr. Benson was the eldest son of the late Dr. John R. Benson, of Beer, in Devon, and was 59 years of age. He studied medicine at the Universities of Edinburgh and Melbourne and was for some time in practice at Gympie, becoming a member of the Queensland Legislative Assembly. Returning to this country he settled in practice at Pontrilas in Herefordshire, and later at St. Peter Port, Guernsey, where he lived for many years. Here Dr. Benson was able to devote some of his leisure to yachting, and in his 20-ton cutter made many cruises along the French and English coasts. In 1911, however, he had to leave his Guernsey practice owing to a breakdown in health which followed infection from a patient upon whom he was operating. He went to Ireland and became resident physician at Farnham House, a mental home in Dublin. Unfortunately, there also ill-health somewhat interfered with his activities, though during the late war he was able to accept a captain's commission in the Royal Army Medical Corps, acting as surgical specialist.

Dr. Benson married, in 1892, the daughter of Mr. S. H. Gabriel, of Calne, in Wiltshire. She survives him with four sons, two of whom—Dr. John Benson and Dr. Wilfred Benson—are members of the medical profession. All four sons saw service in the war.

WALTER THOMAS BEEBY, M.D. ST. AND., M.R.C.S. ENG.

THE death took place in London on Sept. 29th of Dr. W. T. Beeby in his eighty-fifth year. Dr. Beeby was a student of Guy's Hospital, where he was later house surgeon. He graduated as M.D. at the University of St. Andrews in 1862 and three years later went into practice at Bromley in Kent in partnership with the late Mr. J. W. Ilott. On Mr. Ilott's retirement and after his death he continued in practice with his son, Dr. H. J. Ilott. It was largely owing to Dr. Beeby's influence that the Bromley Cottage Hospital was founded in 1869, and he was the first medical officer. The hospital was at first very small, but has since been much enlarged and rebuilt, and is now a well-equipped institution with over 40 beds, having a large staff both of local medical men and of London consultants. Dr. Beeby left England in 1898 and went to live at Rapallo on the Italian Riviera, where he practised for seven years among English visitors and residents and where he had much to do with the building of the English Church of St. George. Later he gave up all medical work and went to live during the winter and spring months at Levanto, further along the coast. Dr. Beeby had a taste for architectural and antiquarian research and was the author of a paper on the Church and Manor of Bromley, and of a little book on the Parish Church.

He married, in 1879, Miss Constance Emily Finley, daughter of the Rev. John Finley, who survives him.

CHARLES STENNETT REDMOND, M.D. N.U.I., L.R.C.P.I.

THE death took place on Oct. 13th of Dr. C. S. Redmond in his eighty-fourth year. He was educated at the Catholic University of Dublin and practised in Manchester from 1900 to 1909, latterly residing at Popefield, Queen's County. The subject of dietetics always interested him and in the district of Manchester where he worked he gave many interesting lectures on food, being a strong believer in the need for educating the public in this subject. In the last part of the war he worked as resident medical officer at the Trafford Hall Red Cross Hospital. The National University of Ireland conferred on him the honorary degree of M.D. in 1915. Dr. Redmond was succeeded in his Manchester practice by his son, Dr. C. H. S. Redmond.

ROBERT PARRY, J.P., M.B. LOND.

Dr. Robert Parry, who died on Oct. 12th, was 71 years of age, and had been in practice at Carnarvon for 43 years. He studied medicine at Owens College, Manchester, and at Guy's Hospital, qualifying as M.R.C.S. in 1879. On going into general practice he became surgeon to H.M. Prison at Carnarvon, medical

officer to the local infirmary, and police surgeon. He took a keen interest in medical and public affairs, and was at one time president of the North Wales branch of the British Medical Association. He entered the town council four years after settling in Carnarvon and remained a member of it till the end of his life. Dr. Parry's fellow citizens showed their appreciation of his work by electing him alderman and mayor in successive years and by making him a freeman of the borough. He was also justice of the peace for the county. He leaves a widow, three sons, and two daughters.

REOPENING OF THE WELLCOME HISTORICAL MEDICAL MUSEUM.

THE rearranged Wellcome Historical Medical Museum was opened on Oct. 14th by Sir Humphry Rolleston, who expressed in his opening remarks the founder's regret at being prevented by philanthropic work in America from receiving his guests personally. Sir Humphry Rolleston referred to the great value of the collection and to the debt we owe to those who have worked to forward the study of medical history in this country.

The Opening Address.

Sir ARTHUR KEITH then delivered an address on "What Museums Should do for Us." He began by showing that geologists in the last century had written the history of the earth, and also of the animals that inhabited it, on their museum shelves, and that history was coming more and more to be written in this way. Pitt-Rivers was the patron saint of curators, and what he had done for human culture in general Mr. Wellcome had done for medicine. The difficulty of illustrating the evolution of medicine by a museum was that, whereas a geological collection illustrated facts, a medical collection had chiefly to illustrate fancies. Primitive medicine and its apparatus were a logical outcome of primitive beliefs based on speculations about the human spirit. No one who studied history intelligently could fail to realise that Mr. Wellcome's Hall of Primitive Medicine, with its totems, fetishes, and mascots, was the primitive counterpart of the stethoscope and the bismuth meal, but having an inner significance which modern apparatus had not. Even educated people still treasured mascots, preferred quacks to qualified men, and believed in spirits. The primitive stage was not yet over. The function of a museum was to foster knowledge, and the money invested in it bore fruit in leaders and teachers. It must be more than a storehouse of material for students; its staff must be students themselves, permeated with the love of knowledge and knowing how to extend it. Besides being active members of learned societies they must give direct education, which needed much discrimination and the art of the window-dresser. Finally, by helping poor men to produce great work, museums were a worthy use of wealth in the service of the community.

Sir FREDERICK KENYON, director of the British Museum, and Sir D'ARCY POWER proposed and seconded a vote of thanks to Sir Humphry Rolleston. A vote of thanks to the founder was proposed and seconded by Mr. W. G. SPENCER, President of the Section of Medical History (Royal Society of Medicine), and Dr. J. D. COMRIE, lecturer in medical history to the University of Edinburgh. It was carried with enthusiasm and acknowledged on behalf of the founder by Dr. C. M. WENYON, director in chief of the Wellcome Bureau of Scientific Research.

The New Museum.

The Wellcome Museum contains a large and well-chosen collection of rare objects, pictures, sculptures, manuscripts, early printed books, &c., illustrating the evolution and practice of medicine and its allied sciences throughout the world in all ages. Founded in 1913 and steadily enlarged since, the museum has no exact counterpart in this or any other country. The exhibits have now been arranged in new cases with superimposed glass shelves, which allow more objects to be shown in the space allotted without overcrowding. No description could convey what a student may learn by spending five minutes—or five hours—in the Italian or Turkish drug shop, and the Primitive Section is a deeper essay in human psychology than was ever printed. A number of additions have been made to the portraits of famous men, to the charming little pomanders and scent-bottles, and to many other sections, and the most interesting new exhibit is the "Lister Ward," reconstructed from the actual Glasgow material and fitted with the original equipment. Personal relics of Lister displayed near by include his academic robes, diplomas, and research apparatus, and the carbolic sprays he used when he first introduced antiseptic surgery.

Wellcome Historical Medical Museum. (*Copyright.*)

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a quarterly meeting of the Council on Oct. 14th Sir Berkeley Moynihan, the President, reported that the Supplementary Charter which had been approved by the King in Council on July 26th had been duly received. The annual report of the Council to be presented to the Fellows and Members at the annual meeting on Nov. 18th was approved and will be circulated. The President also reported that the Thomas Vicary Lecture on the Significance of Anatomy will be delivered by Prof. G. Elliot Smith on Thursday, Nov. 4th, at 5 P.M.; and that the Bradshaw Lecture on Reconstructive Surgery of the Hip-joint will be delivered by Prof. Ernest W. Hey Groves on Thursday, Nov. 11th, at 5 P.M.

Mr. Kenneth Swire Southam, late of Epsom College, was nominated as the thirty-fourth Jenks Scholar.

The diploma of Fellow was conferred upon John Lewin, of Guy's Hospital.

Diplomas of Member were conferred upon the following:—

Winifred M. de Kok, Cape and Royal Free; T. C. Hunt, Oxford and St. Mary's; S. M. Mallick, Lahore and Guy's; A. W. L. Row, Oxford and St. Bart.'s; H. Smith, Cambridge and St. George's; Karin Stephen, Univ. Coll.; H. Syed, Bombay and King's Coll.; and J. G. T. Thomas, Cambridge and St. Mary's.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual dinner will be held at the Piccadilly Hotel, London, W. 1, on Thursday, Nov. 18th, at 7.10 for 7.30 P.M. Ladies are invited. Members are asked to give early notice to the executive secretary of their intention to be present.

NORTH-WESTERN TUBERCULOSIS SOCIETY.—The opening meeting of the new session will be held at the tuberculosis offices, Joddrell-street, Hardman-street, Deansgate, Manchester, on Thursday, Oct. 28th, at 3.15 P.M., when Dr. Alfred Adams, medical superintendent, Liverpool Sanatorium, Delamere, will give his presidential address on Tuberculosis: the Prospect.

ROYAL INSTITUTION.—On Tuesday, Nov. 2nd, at 5.15 P.M., Mr. G. W. C. Kaye, D.Sc., will deliver the first of three lectures on the Acoustics of Public Buildings, and on Tuesday, Nov. 23rd, Sir William Bragg will begin a course of four lectures on the Imperfect Crystallisation of Common Things. On Thursday afternoons, beginning on Nov. 4th, there will be two lectures by Sir Edgeworth David on Antarctic Exploration Past and Future; three by Dr. R. R. Marett on the Archæology of the Channel Islands, and two by the Editor of THE LANCET on Early Medical Literature (Dec. 9th), and Medical Literature in Relation to Journalism (Dec. 16th). The Juvenile Lectures will be delivered by Prof. A. V. Hill on Nerves and Muscles: How We Move and Feel. They will begin on Dec. 28th.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Practitioners interested in the series of lectures on Emergencies in Medicine and Surgery should note that Mr. Herbert J. Paterson will lecture on Monday, Oct. 25th, on Gastric Hæmorrhage and Perforation of Ulcers, and that on Thursday, Oct. 28th, Mr. Arthur Cheatle will lecture on Emergencies in Aural Disease. The lectures will be delivered in the Lecture Hall of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., at 5 P.M. On Friday, Oct. 29th, at 5 P.M., at the Royal Westminster Ophthalmic Hospital, Charing Cross, Mr. C. L. Gimblett will give a lecture-demonstration on the Investigation of Visual Fields. Both lectures and demonstration will be open to members of the medical profession, without fee. During November a course in Venereal Disease will be given at the London Lock Hospital. From Nov. 15th to Dec. 4th a course in gynæcology and diseases of children will be available at the Royal Waterloo Hospital. Special reference will be made to endocrine deficiency, to diseases of the blood, thyroid, breast, and stomach, and to gynæcological diagnosis. The St. John's Hospital will hold a clinical course, with bi-weekly lectures in dermatology, from Nov. 15th to Dec. 11th. If desired a course in pathology can also be arranged. From Nov. 22nd to 27th there will be a week's course in Rectal Diseases at St. Mark's Hospital. For those who have little time at their disposal there are two late afternoon courses: from Nov. 1st to 13th, 4.30 to 6 P.M., a course in general medicine, surgery, and the specialties at the Hampstead General Hospital; and from Nov. 22nd to Dec. 18th a series of lecture-demonstrations on selected neurological cases in the West End Hospital, 73, Welbeck-street, London, W., at 5 P.M. Copies of all syllabuses, of the General Course Programme, and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

UNIVERSITY OF WALES.—In the second part of the examination for the diploma of public health Dr. Doris Williams has satisfied the examiners.

Messrs. Cassell and Co. announce the publication of "X Ray Diagnosis: A Manual for Surgeons, Practitioners, and Students," by Mr. J. Magnus Redding, senior surgical radiologist to Guy's Hospital. It is illustrated with 224 skiagrams from Mr. Redding's collection.

MEDICO-LEGAL SOCIETY.—A meeting will be held at 11, Chandos-street, Cavendish-square, W. 1, on Thursday, Oct. 28th, at 8.30 P.M., when a paper will be read by Dr. John Glaister, Jun., on the Results of Recent Experimental Work upon the Serological or Precipitin Test for the Detection of Blood, considered from the Medico-Legal Aspect. A discussion will follow. Members may introduce guests on production of a member's private card.

UNIVERSITY OF BRISTOL.—The annual dinner of the Association of Alumni (London branch) will be held at the Hotel Cecil, Strand, on Friday, Oct. 29th, at 7.30 for 7.45 P.M. Lord Haldane will preside, and Dr. T. F. Sibly, principal officer of the University of London, will be the guest of the evening. The dinner will be followed by dancing. Application for tickets may be made to Dr. Elizabeth Casson, Holloway Sanatorium, Virginia Water.

UNIVERSITY OF EDINBURGH: A NEW CHAIR.—Lord Woolavington has given £10,000 towards the foundation of a chair of animal breeding at the University. The gift follows on an announcement by the Rockefeller International Education Board of a grant of £30,000 for the extension of the animal breeding department of the University, on condition that a similar sum was obtained in this country (vide THE LANCET, August 14th, p. 341). The director of the department is Dr. F. A. E. Crewe.

TRIBUTE TO THE LATE DR. ADAMI.—The Council and Senate of the University of Liverpool have held special meetings to put on record their profound regret at the death of the Vice-Chancellor, Dr. J. G. Adami, and a special commemoration service, held at the Liverpool Cathedral on Oct. 15th, was attended by a large and representative congregation from the University, City and adjacent towns.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION. This association has issued a syllabus for the winter session containing information about courses of lectures and demonstrations and arrangements for the appointment of clinical assistants. Copies of the syllabus may be had from the Secretary of the Association at the University, Glasgow.

IRISH PUBLIC HOSPITALS AND MEDICAL FEES.—The Irish Minister of Local Government and Public Health has given his decision on the facts brought out in the recent sworn inquiry in County Clare into the practice of charging medical fees to certain patients admitted to the public hospitals (THE LANCET, Sept. 25th, p. 676). The Minister finds that a demand was made for fees in two cases by Dr. T. E. O'Connor, medical officer in charge of the Raheen Hospital. He states that Dr. O'Connor appeared to rely for justification on regulations adopted by the County Board of Health for the admission of paying patients, but he points out that these regulations could not become effective without the Minister's approval, and such approval had not been given. While the Minister "takes a very serious view of Dr. O'Connor's action," he does not propose to take any disciplinary steps. He adds some paragraphs explaining the present position as regards the admission of paying patients to county institutions: "The hospitals provided under the county scheme," he states, "are intended for persons eligible for relief, and the officers of these hospitals are employed and paid by the Board for the purpose of giving their services gratuitously to the persons eligible for relief admitted to those hospitals." Article 42 of the General Regulations provides that "no officer appointed by the Board of Health shall be entitled to demand, receive or accept any fee or payment from any person in receipt of assistance . . . . Power is given to the Board to admit persons who are not eligible for relief to the hospitals, subject to such regulations and conditions as to payment by and accommodation for such persons, or otherwise, as may be approved by the Minister." The medical officers, he says, have not power to regulate the admission of any class of patients to the hospitals, and in the absence of regulations approved by the Minister there is no legal authority under which private patients can be admitted to the hospitals, and the medical officers are not authorised to demand, receive, or accept any fee or payment from any patient treated in the hospitals. It is to be noted, writes our Irish correspondent, that the Minister refrains from any expression of opinion on the propriety of the admission of paying patients, and of allowing the medical officers to charge fees. He deals only with the legal position as it affects County Clare at the present moment. It appears that it is illegal either to admit paying patients or to charge them fees.

Dr. A. D. Macdonald has been appointed lecturer in experimental physiology at the Victoria University of Manchester.

SERVICE HOSPITALS AT PORTSMOUTH.—Arrangements have been made for the reception into the Royal Naval Hospital at Haslar of cases from Army and Air Force units. The Alexandra Hospital, now given up by the Army, has been taken over by the Ministry of Pensions, although an attempt was made to secure it for the use of the city as an adjunct to the Royal Portsmouth Hospital.

GUILD OF ST. LUKE.—The annual service of the Guild was held in Westminster Abbey on Oct. 17th. So large was the congregation that many had to stand throughout the service. Members of the Guild, in academic robes and headed by their banner, formed a procession which preceded that of the choir and cathedral clergy. The lesson was read by the Rev. H. Kirkland-Whittaker, M.B., secretary to the Guild, and the preacher was the Rev. Canon Sopwith, vicar of Maidstone, who took as his text, "The Beloved Physician." Before pronouncing the blessing the Dean of Westminster read the special collect of the Guild.

BIRMINGHAM HOSPITALS: AN IMPORTANT GIFT.—In connexion with the scheme for equipping Birmingham with a hospital centre, Messrs. Cadbury Brothers, Ltd., have offered to give the city about 150 acres of land adjoining the University. It is suggested that the whole of the land shall become the property of the city on the understanding that the council, in consultation with the Hospitals Council for the City of Birmingham, shall select and reserve for hospital purposes about 100 acres of the land and grant long leases to the hospital authorities at nominal rents. It is hoped that the remainder of the land will be used for playing fields. Messrs. Cadbury have offered £5000 as a donation towards the expenses of the city council in acquiring and dealing with the site.

THE Council dinner of the British Medical Association was held at the House of the Association on Wednesday, Oct. 13th, when Sir Robert Bolam presided over a large gathering. The toast list made opportunity for a series of pleasant speeches, most of which were brief, by definite instruction from the chair. Dr. J. A. Macdonald proposed the health of the retiring President, Dr. F. G. Thomson, who refused in his reply to consider what had been termed his "swan-song" as implying cessation of activity in Association matters. Dr. C. O. Hawthorne spoke amusingly to the toast of the "Common Health," which he coupled with the name of the Director-General of the Army Medical Service, Sir Matthew Fell. Dr. Arnold Lyndon proposed the health of "The Guests," when replies were made by Commander Hilton Young, M.P., and Sir Martin Conway, M.P., the former of whom made entertaining allusions to his position as the one lay member of the General Medical Council. The health of the Chairman was proposed by Dr. E. R. Fothergill.

MEDICAL GOLFING SOCIETY.—The autumn meeting was held at Littlestone Golf Club on Oct. 17th and 18th in good weather. C. V. MacKay won the Max Page Prize (singles *v.* bogey) after a tie with Herdman Porter. H. W. Carson and A. E. Mortimer Woolf won the foursomes *v.* bogey with 1 down. The following tied for second place with 2 down: G. Dawson and J. D. O'Keefe; T. P. Kolesar and W. R. Bristow; L. Bromley and H. Chapple; P. Gosse and A. Hope Gosse; H. C. Apperley and E. A. Hardy. The Canny Ryall Cup was won by Harold Chapple with the score of 85−15=70. C. Max Page (80−6) and V. E. Negus (85−11) tied at 74 for second and third places. A. Scott Gillett was fourth with 86−11=75. The best scratch score (74) was done by T. P. Kolesar.

The *Ladies Medical Golfing Society* will hold their autumn meeting at Walton Heath Golf Club on Oct. 26th.

SMALL-POX IN SOUTH SHIELDS.—In regard to the fatal case of small-pox reported last week in South Shields county borough, the medical officer of health, Dr. W. Campbell Lyons, inform us that the patient had been under medical care for about four months and was an "old clothes" dealer. A rash appeared on Sept. 16th, but was not notified to him until the 20th, when the woman was removed to hospital. The case was one of confluent small-pox with large hæmorrhagic bullæ on the back of the hands and the loins. On the parts of the skin which were not covered with small-pox spots, there was a peculiar petechial rash. As the case was from a very unhealthy quarter of the town, a Weil-Felix reaction was done but proved negative 1 in 20. The Wassermann reaction was strongly positive. The patient had a mitral and aortic lesion and atheroma, and developed hypostatic pneumonia two days before she died. Several cases of small-pox had occurred in the neighbourhood, and while the primary source of infection has not yet been established, Dr. Lyons has no doubt that this fatal case had been in contact with one or other of the former cases.

NAVAL MEDICAL COMPASSIONATE FUND.—At a meeting held on Oct. 19th, Surgeon Vice-Admiral Sir Joseph Chambers in the chair, the sum of £114 was distributed among the several applicants.

ROYAL SANITARY INSTITUTE.—The thirty eighth congress of the Institute will take place next year at Hastings from July 11th to 16th. At an exhibition held in connexion with it there will be displayed appliances for housing and general sanitation and other matters relating to health and physical welfare. Information may be had from the secretary of the Institute at 90, Buckingham Palace-road, London, S.W. 1.

COOMBE HOSPITAL CENTENARY CONGRESS.—An international gynæcological and obstetrical congress was held in Dublin recently to commemorate the centenary of the Coombe Lying-in Hospital (vide THE LANCET, Sept. 25th, p. 673). The papers read at the congress are to be published by the *Irish Journal of Medical Science* and may be ordered from the circulation manager of that journal at Parkgate Printing Works, Dublin (price 5*s.* 6*d.*, including postage).

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—The following awards have been made:—

Senior Scholarship for General Clinical Studies, Todd Prize for Clinical Medicine, Special Prize for Diseases of Children and for Orthopædic Surgery: F. Goldby, M.R.C.S., L.R.C.P., Jelf Medal, awarded annually on the Senior Scholarship Examination to the Candidate who is second in order of merit: A. W. Kendall, M.R.C.S., L.R.C.P. Burney Yeo Scholarship: R. G. Macbeth, B.A., Oriel College, Oxford. Burney Yeo Scholarship (Honorary): T. K. Lyle, B.A., Sidney Sussex College, Cambridge. Burney Yeo Exhibition, F. C. Mayo, B.A., Pembroke College, Cambridge. Burney Yeo Exhibition: C. R. L. Orme, B.A., Sidney Sussex College, Cambridge. Raymond Gooch Scholarship: S. R. C. Price, B.Sc., King's College, London. Tanner Prize for Obstetric Medicine: A. P. Ross. Special Prize for Diseases of Children: J. L. Newman, B.A. Special Prize for Orthopædic Surgery: H. L. C. Wood.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—The opening meeting of the session was held at the British Medical Association House on Oct. 12th, when the proceedings opened with the induction of the new president, Miss Elizabeth Bolton, into the chair, by Dr. Christine Murrell, the retiring president. After a vote of thanks to Dr. Murrell for her services, the meeting proceeded to business. Reports were presented from the sub-committee on menstruation and from the sub-committee on cancer research, and other business was discussed. Miss Bolton then delivered her presidential address, choosing for her subject Some Aspects of Disease of the Cæcum. She dealt with the subject mainly from the points of view of diagnosis and the results of operative treatment, first discussing carcinoma of the cæcum, with illustrative case records, and then going on to describe a variety of rarer conditions often difficult to differentiate from malignant disease. Among these were actinomycosis of the cæcum, inflammatory masses associated with chronic appendicitis, fibrolipomatous polyp of the bowel complicated by torsion of an ovarian fibroma, and chronic appendicitis associated with ovarian fibroid. These were all illustrated by cases and by a series of slides and museum specimens. The results of operation were uniformly good, she said, in the non-malignant cases. A short discussion followed.

MEDICAL SICKNESS AND LIFE ASSURANCE.—The annual general meeting of the Medical Sickness Annuity and Life Assurance Society, Ltd., was held at the offices of the company, Lincoln House, 300, High Holborn, London, W.C. 1, on Oct. 11th, Dr. F. J. Allan in the chair. In his opening remarks the Chairman said that allowing for incidental variations the figures showed steady increase of membership year by year; the benefits accruing to members under sickness and accident policies were the best obtainable, and the directors had decided to give even greater benefits, to apply to both existing and new policies. Members going on holiday in certain countries for a period not exceeding three months would remain covered without payment of any extra premium, and the directors always took a sympathetic view of cases in which, perhaps, the requirements under the rules had not been strictly complied with. The reason why the amounts paid out had not increased in the same proportion as the membership was chiefly the careful medical examination of proposers. He regretted, he said, that Dr. David Forsyth, who had acted as the medical adviser of the society since 1920, had found it impossible to continue to act for the society, which had therefore secured the services of Dr. A. Hope Gordon in his stead. During the last year the sums insured in life assurance had been for lower amounts; this was attributable to the effect of the general depression caused through the coal strike. Dr. F. J. Allan and Mr. W. H. Dolamore, M.R.C.S., were re-elected directors.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MONDAY, Oct. 25th.—8 P.M., ODONTOLOGY. Mr. J. B. Parfitt: Presidential Address. Paper: Mr. C. A. Wakeford: Some Observations on the Tooth Band and on the Enamel Organs of the Human Deciduous Teeth.
TUESDAY.—5 P.M., MEDICINE. Clinical meeting at Guy's Hospital. Tea will be served in Mary Ward at 4.45 P.M. Cases and demonstrations.
WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Sir D'Arcy Power: Presidential Address.
THURSDAY.—8.30 P.M., UROLOGY. Mr. W. Girling Ball: Some Anatomical Factors in Urinary Affections.
SATURDAY.—STUDY OF DISEASE IN CHILDREN. Provincial meeting (postponed from last session) at the Children's Hospital, Ladywood-road, Birmingham. Train from Paddington (restaurant car) 11.10 A.M. Reduced first-class return fare 23*s.* 1*d.* Those requiring tickets should write to Dr. Neill Hobhouse (18, Harley-street, W.) by midday, Thursday, Oct. 28th.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Oct. 25th.—8 P.M., Clinical meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
MONDAY, Oct. 25th.—5 P.M., Mr. C. E. Shattock: Surgical Conditions of Blood-vessels.
FRIDAY.—5 P.M., Sir Arthur Keith: Specimens illustrating Disorders in the Growth of Bone. (Demonstrations open to advanced students and medical practitioners.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Oct. 25th, to SATURDAY, Oct. 30th.—FELLOWSHIP OF MEDICINE (Special Lectures), Medical Society of London, 11, Chandos-street, Cavendish-square, W. Mon., Oct. 25th, Mr. H. J. Paterson: Gastric Hæmorrhage and Perforation of Ulcers. Thurs., Mr. Arthur Cheatle: Emergencies in Aural Disease.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross. Fri., 5 P.M., Mr. Gimblett: Special Lecture-Demonstration on Investigation of Visual Fields.—COMBINED COURSE IN DISEASES OF CHILDREN, Paddington Green, Victoria Hospital and Children's Clinic. All-day course.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Post-graduate course in gynæcology. Operations, demonstrations, and lectures.—ST. PETER'S HOSPITAL, Henrietta-street, W.C. Clinical course in genito-urinary diseases, including cystoscopies and formal lectures. The lecture at the Medical Society and the demonstration at the Royal Westminster Ophthalmic Hospital are free to members of the medical profession without fee. Further information from the Secretary of the Fellowship of Medicine.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, Oct. 25th.—10 A.M., Mr. MacDonald: Genito-Urinary Operations. 12 noon, Mr. Simmonds: Fractures and Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.
TUESDAY.—12 noon, Dr. Burrell: Demonstrations of Chest Cases. 2 P.M., Mr. Addison: Operations. 2 P.M., Mr. Sinclair: Surgical Out-patients.
WEDNESDAY.—10.30 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards. 2 P.M., Dr. Owen: Medical Out-patients.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. Bishop Harman: Eye Dept.
FRIDAY.—10 A.M., Sir Henry Simson: Gynæcological Operations. 10.30 A.M., Dr. Dowling: Skin Dept. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Dept.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Dept. 10 A.M., Dr. Saunders: Medical Diseases of Children.
Operations, Medical and Surgical Out-patients, Special Departments, daily, 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 1 P.M.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Oct. 25th.—2 P.M., Medical Cases in the Wards. 2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.
WEDNESDAY.—2.30 P.M. to 5 P.M., Medical Skin and Eye Clinics. Operations.
THURSDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.
FRIDAY.—2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
On Monday, Oct. 25th, and Friday, Oct. 29th, at 2.30 P.M., there will be special demonstrations of gynæcological cases and medical cases (children) by Mr. Aubrey Goodwin and Dr. Bruce Williamson respectively.

POST-GRADUATE HOSTEL, Imperial Hotel, Russell-sq., W.C.
MONDAY, Oct. 25th.—9 P.M., Discussion: Colour Vision and Colour Blindness, opened by Prof. Roaf.
THURSDAY.—9 P.M., Symposium: The Filled Dead Tooth as a Source of Streptococcal Blood Infection. Open discussion. Dinner 8 P.M. 5*s.*

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Oct. 26th.—5 P.M., Dr. H. W. Barber: Immunity and Anaphylaxis.
THURSDAY.—5 P.M., Dr. W. Griffith: Principles of Treatment. General.

NATIONAL HOSPITAL, Queen-square, Bloomsbury, W.C.
MONDAY, Oct. 25th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: Cerebellar Syndromes.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Hinds Howell: Muscular Atrophy.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Riddoch: Some Sequelæ of Encephalitis Lethargica.
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Collier: Peculiar Maladies of the Fifth and Seventh Cranial Nerves, Neuralgia, Hemiatrophy and Spasm.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street.
THURSDAY, Oct. 28th.—4 P.M., Dr. Frew: Mental Deficiency.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Oct. 27th.—4 P.M., Prof. L. P. Abercrombie: Town and Regional Planning in its Effects upon the Distribution of the Population.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Oct. 26th.—4.15 P.M., Dr. J. Wharton: Eye Cases.
FRIDAY.—4.15 P.M., Dr. Archibald Donald: Uterine Cancer.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS
FRIDAY, Oct. 29th.—3.30 P.M., at the Royal Infirmary: Prof. Connell: Lesions of the Vertebral Column.

ST. MARGARET'S HOSPITAL FOR WOMEN, Acomb-street, Whitworth Park, Manchester. Post-Graduate Lectures.
WEDNESDAY, Oct. 27th.—4 P.M., R. R. Kerr: The Diagnosis and Treatment of Abdominal Tuberculosis in Young Girls.

ANCOATS HOSPITAL POST-GRADUATE COURSE.
THURSDAY, Oct. 28th.—4.15 P.M., Mr. Harry Platt: Treatment of Common Injuries.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.
TUESDAY, Oct. 26th.—4 P.M., Prof. John Shaw Dunn: Disturbance of Renal Function in Experimental Nephritis. Discussion to be opened by Dr. A. Rowand.

Appointments.

MACDONALD, A. D., M.B., Ch.B. Edin., has been appointed Lecturer in Experimental Physiology in the University of Manchester.

STEELE, RUSSELL V., M.B., B.S. Durh., Medical Officer to School for the Blind, Swiss Cottage, N.W.

SUDLOW, G. W., M.B., B.S. Lond., Certifying Surgeon under the Factory and Workshop Acts for the Hanley District of the County of Stafford.

Manchester Royal Infirmary: Caithness, J. F., M.B., Ch.B. Vict., Shepley, W. H., M.B., Ch.B. Vict., Keddie, J. T. C., M.B., Ch.B. Vict., Whitley, J. T., M.B., Ch.B. Vict., House Physicians; Pendlebury, R., M.B., Ch.B. Vict., Mitchell, D. E. L., M.R.C.S., L.R.C.P., Anderson, J. K., M.B., Ch.B. Vict., Moll, G. S. W., M.B., Ch.B. Vict., Roff, C. D., M.B., Ch.B., House Surgeons; Gerrard, E. A., M.B., Ch.B. Vict., House Surgeon Specials Department; Mumford, P. B., M.D. Vict., re-appointed Assistant to the Dermatologist; Linford, Hilda, M.B., Ch.B. Vict., Clinical Assistant, Surgical; Langford, G. F., M.B., Ch.B. Vict., Resident Clinical Pathologist; Ellis, R., M.B., Ch.B. Vict., Cardiographic Registrar; Morris, L., F.R.C.S. Eng., Surgical Registrar; Whitrow, F., M.B., Ch.B. Vict., Clinical Assistant, Medical; Susman, W., M.D., Junior Pathological Registrar; Drinkwater, S. W., M.B., Ch.B. Vict., Second Surgical Registrar; Gow, J., F.R.C.S. Vict., Assistant Surgical Officer at the Central Branch; Sutherland, D. M., F.R.C.S. Eng., Assistant Surgical Officer; Edwards, M. E., M.B., Ch.B., Vict., Stubbs, J. B., M.B., Ch.B. Vict., Assistant Medical Officer at the Central Branch.

Vacancies.

For further information refer to the advertisement columns.

Bethlem Royal Hospital, Lambeth-road, S.E.—Jun. Asst. P. £350.
Bradford Royal Infirmary.—H.S. £150.
Bury St. Edmunds, West Suffolk General Hospital.—Res. H.S. £180.
Cambridge, Addenbrooke's Hospital.—Electrical and X Ray Dept. Asst. P.
Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100.
Central London Ophthalmic Hospital, Judd-street, W.C.—Asst. Surg.
Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W.C.—Asst. S. Also Hon. Asst. Anæsthetist.
Chichester, West Sussex County Mental Hospital—Med. Supt. £900.
City of Sheffield.—Jun. Asst. Tub. O. £350.
Coventry and Warwickshire Hospital, Coventry.—Res. H.S. £125.

Freemason's Hospital and Nursing Home, 237, Fulham-road, Chelsea, S.W.—Res. M.O. At rate of £250.
Great Yarmouth General Hospital.—H.S. £150.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Asst. P.
Hospital for Sick Children, Great Ormond-street, W.C.—Bio-Chemist. £600.
Kingston-upon-Hull, Infectious Diseases Hospitals.—R.M.O. £547 9*s.* 5*d.*
Lancashire Education Committee, Edge Hill Training College, Liverpool.—Visiting Med. O. 100 guineas.
Lancaster County Mental Hospital.—Med. Supt. £800.
Leeds, Jewish Herzl Moser Hospital, Leopold-street.—Res. M.O. £50.
Liverpool, Brownlow Hill Infirmary.—Res. Asst. M.O. £200.
London Female Lock Hospital, 283, Harrow-road, W.—Hon. Obstet. S.
London Temperance Hospital, Hampstead-road, N.W.—Hon. P. Also Clin. Asst. in Cas. Dept.
M.A.B. Highwood Hospital for Children, Brentwood, Essex.—Jun. Asst. M.O. for cases of Pulmonary Tuberculosis. Also Jun. Asst. M.O. in Mental Hospital Service. Each £500.
Macclesfield General Infirmary.—Second H.S. £150.
Manchester, Ancoats Hospital.—Anæsthetist. 10*s.* 6*d.* per attendance. Also Pathological Registrar. £100.
Manchester Corporation, Public Health Dept.—Asst. M.O.H. (Maternity and Child Welfare). £850. Also Asst. M.O.H. £750.
Manor House Hospital, Golders Green, N.W.—Asst. S. £750.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Asst. P. and two Asst. S.'s.
Northumberland, Wooley Sanatorium, near Hexham.—Med. Supt. £850.
North Middlesex Hospital, Edmonton, N.—App. to Medical Electricity and Light Department. 3 guineas per session.
Norwich, Norfolk and Norwich Hospital.—H.S. for Ear, Nose and Throat and Ophth. Dept. £120.
Otago University and Dunedin Hospital, New Zealand.—Medical Tutor and Sen. Res. M.O. Also Sen. Res. Surg. O. Each £400.
Penshurst, Kent, Cassel Hospital for Functional Nervous Disorders. Res. M.O. £350.
Royal Free Hospital, Gray's Inn-road, W.C.—Sen. Res. M.O. £150.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Non.-Res. Cas. O. £150. Also H.S. At rate of £100.
St. Mary's Hospital, W.—Phys. for Mental Diseases.
Sheffield, Winter-street Hospital.—Jun. Asst. Tub. O. £350.
West London Hospital, Hammersmith, W.—Phys.
Winchester, Royal Hampshire County Hospital.—Res. M.O. £200.
Woolwich Union Infirmary, Plumstead High-street, S.E.—Second Asst. M.O. £300.

Births, Marriages, and Deaths.

BIRTHS.

MACFIE.—On Oct. 13th, at "Penrhyn," Bayshill-road, Cheltenham, the wife of R. Bute Macfie, F.R.C.S. Edin., of a son.
MURPHY.—On Oct. 14th, at Hernbury House, Linthorpe, Middlesbrough, the wife of Robert Walpole Murphy, O.B.E., M.D., of a daughter.

MARRIAGES.

GRIMMER—SELWYN.—On Oct. 7th, at Holy Trinity Church, St. Nicholas-road, S.W. 17, by the Rev. J. W. Craufurd, Murray, M.A., Vicar of the Parish, George Kerr Grimmer, B.A., M.D., F.R.C.S.E., 282, Balham High-road, S.W. 17, and 11, Wimpole-street, W. 1, to Lilian Florence Nash Selwyn, widow of George Alexander Selwyn, 23, Boundaries Mansions, S.W. 12.
SCHOFIELD—ATKINSON.—On Tuesday, Oct. 12th, at the Parish Church, Morecambe, by the Rev. T. H. Bywater, M.A., vicar of Outwood (uncle of the Bridegroom), assisted by the Rev. T. Mercer, M.A., vicar of St. Anne's, Lancaster, and the Rev. E. A. Seymour Scott, M.A., rector of Morecambe, James Mortimer Schofield, M.R.C.S. Eng., L.R.C.P. Lond., elder son of the late C. D. Schofield, of Bradford, and of Mrs. Armitage, Minden Bray, Epsom Downs, Surrey, to Marjorie, elder daughter of T. Atkinson, Esq., J.P., and Mrs. Atkinson, of Berwyn, Morecambe. At Home Nov. 2nd, Gairloch, Bare, Morecambe.

DEATHS.

ALLAN.—On Sept. 8th, at The Peak, Hong-Kong, James Cyril Dalmahoy Allan, M.D., in his 45th year.
GABELL.—On Oct. 14th, at his residence, South Croxted-road, Dulwich, Douglas Phillimore Gabell, M.R.C.S., L.R.C.P., L.D.S. R.C.S.E.
GIBBONS.—On Oct. 15th, suddenly, in his surgery, at Malden-crescent, N.W., while attending a patient, Charles James Preston Telford Gibbons, M.R.C.S., L.R.C.P.
LAPAGE.—On Oct. 14th, at Dolywern, Charles Clement Lapage, M.A., M.D. Cantab., M.R.C.S., L.S.A. (retd.), aged 75 years. Late of Nantwich, Cheshire.
PARRY.—On Oct. 12th, at Ty Newydd, Carnarvon, North Wales, Dr. Robert Parry, J.P., aged 71 years.
PARSON.—On Oct. 11th, at Bondfield, Bursledon, Hampshire, Henry Parson, M.R.C.S., L.R.C.P., aged 75 years.
REDMOND.—On Oct. 13th, at Scorton, Yorkshire, Charles Stennett Redmond, M.D., aged 83 years.

N.B—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

PUBLIC HEALTH IN GERMANY.

ON Monday, Oct. 18th, Prof. Rudolf Abel, of the University of Jena, gave, at the Royal Society of Medicine, the first of two Chadwick lectures on the Development and Present State of Public Health in Germany. The main object of the lectures is to compare English and German conditions and explain the reasons for their difference.

After describing the bad state of affairs at one time prevailing in Germany, Prof. Abel referred to the progress in hygiene noticeable during the eighteenth century—progress which ceased, however, owing to the poverty caused in Germany by the wars of Napoleon. This poverty did not allow of many improvements being made, a notable exception being a campaign against small-pox, following the investigations of Jenner into vaccination. About 1840 England undoubtedly took the lead in hygienic legislation and practical sanitation, since her industrial development obliged her to pay attention to these matters. In this respect she was for a long time the instructor of Germany, whose special contributions to knowledge were rather those of Pettenkofer in scientific hygiene and Robert Koch in bacteriology. It was only after the foundation of the German Empire, in 1871, that practical measures of public health underwent much development. The conversion of Germany from a generally agricultural country into an industrial one, and the enlargement of towns which this involved, was carried out without any damage thanks to improvements in hygiene; and, in fact, sanitary conditions steadily improved.

To the late war Prof. Abel attributed very serious impairment of the public health due to the blockade. Nearly 800,000 persons perished in Germany from want of food and from diseases consequent on it, and the development of children suffered greatly. Since its end, however, all possible measures have been taken, in spite of economic distress, to improve the standard of public health again; these measures are having good results.

Referring to health legislation and administration, Prof. Abel pointed out that the establishment of institutions for public health rests in Germany, as a matter of course, on the local authorities, who do not need any special authorisation by a Public Health Act as they do in England. Medical officers of health are all State officials and receive their salaries from the Government, but the cost of institutions and works is borne by the local authorities, and only exceptionally by the State, whose expenditure for sanitary purposes is, therefore, small.

In conclusion, Prof. Abel showed comparative diagrams and tables of the mortality- and birth-rates in England and Germany. During the past 50 years mortality has been falling more in Germany than in England, so that the two countries are now nearly on a level; but the birth-rate is decreasing in Germany more than in England. This latter fact is causing anxiety in Germany, and efforts are being made to raise the birth-rate, to reduce infant mortality, and to improve the health of children.

Prof. Abel expressed his satisfaction that interest should be shown in England in German hygiene; in Germany, he said, English public health work is carefully studied.

SUDDEN WHITENING OF THE HAIR.

THE *Bruxelles Médical* has been holding an inquiry into this intriguing riddle of the whitened hair, and in a recent issue it reprints from the *Revue Pratique de Biologie Appliquée* a survey by Mr. Carrion, the well-known biologist, of the literature on the subject. He has had no trouble in finding instances among the ancients, for they were full of the phenomenon, and the chief difficulty of the annotator was to choose. His first example is a delightful one from Aventinus in the Annals of the Boii. The Emperor Louis was away at the wars, and his wife sent him a letter with a black seal. To the same messenger she entrusted a letter to her lover with a red seal, but the man mixed up the two letters. The enraged Emperor left his armies and returned home at top speed, where he executed his wife, stabbed her girl accomplice, and threw the keeper of the women's quarters from the ramparts. In a paroxysm of remorse for this triple slaughter he saw a vision so horrible that his hair turned white. As a form of penance he built and endowed a monastery, but Aventinus omitted, as Mr. Carrion remarks, to relate whether this treatment succeeded in restoring his hair to its normal colour. The story is typical of all the other traditional examples, which give as the cause of the hair turning white imprisonment, a death sentence, or the slipping of the rope from which a birds-nester hung on a cliff face. The phenomenon has always had a powerful appeal to superstitious minds, and it is recorded that a pope, who had refused a bishopric to a candidate, changed his mind when the man appeared next morning with white hair.

Schenkins tells of a peasant whose beard grew white upon certain birth marks which were due to a fright his mother had sustained during pregnancy. More recent is the note in Charcot's "General Anatomy" of a passage in Alibert describing the effect on a man of three pieces of bad news which he had received at different times in his life; the first turned half his beard white, the second turned the hair on the same side of his head, and the third whitened a tuft of hair that grew on his shoulder. Sollier reported to the Society of Military Medicine and Surgery of Montpelier in 1916 the case of a soldier who had been buried for half an hour in a mine explosion and who was treated for a severe burn on his face. When the dressing was removed three days later the growing hair was quite white; the patient also suffered from epistaxis, headache, generalised spasm, and mental confusion. These symptoms and the whiteness both disappeared by degrees. The soldier admitted that he had been extremely frightened at the time. Mr. Bernard, who conducted our contemporary's inquiry, produced among three examples one of a woman spy of 32 who was sentenced to be shot. When she was led out at dawn of the following day her chestnut hair had turned white. Captain Prother, of the *Carpathia*, who went to the aid of the stricken *Titanic*, tells that most of the corpses taken from the water, even the children, had white hair. The explanations suggested by modern authorities are disappointing. That of Landois and Pfaff in the last century, that the skin had secreted, under the influence of emotion, a bleaching substance akin to chlorine, and that of Mr. Bertrand, that movement in the sympathetic part of the cortex set up an aberrant reflex action which might inhibit the supply of pigment, do not speak well for the neurological science of that time. Mr. Fafner, expounding in the *Libre Belgique* his hypothesis of a neuropsychological inhibition of thyroid secretion, does at any rate indicate a line of possible inquiry, but no one has improved on Lemnius, who said that the same mechanism that drove the blood from the skin drove inwards also the fluid with which the skin nourished the roots of the hair. If the phenomenon of sudden blanching does exist—and the circumstantial evidence for its existence is strong—the answer will presumably come as a by-product of new investigation into the working of the sympathetic nervous system. Meanwhile, the riddle remains unanswered. Incidentally, if Mr. Carrion is always as entertaining as he is in this summary, it must be a joy to learn biology from him.

A STUDENTS' GUIDE.

"Technical Education," by Mr. J. C. Ghosh, B.Sc., F.C.S. (Thacker, Spink and Co., Calcutta and Simla, 1926, pp. 316, Rs.4.8), is a guide to careers for young Indians in the public services, commerce, and industry. Since the author is the principal of the Calcutta School of Technology the larger part of the book is devoted to this subject and its possibilities. These lead him to a discussion of the public health problems of his country, and the scope for research and routine work in such subjects as the value and standardisation of indigenous drugs, scientific agriculture, preventive medicine, chemical analysis, and the provision of pure bread. The appendices form a students' guide to the educational facilities and government services of the country, including the Indian Medical Service.

NATIONAL COUNCIL FOR THE UNMARRIED MOTHER AND HER CHILD.

THE work of the National Council for the Unmarried Mother and her Child, which has just issued its eighth annual report, is becoming more stable and more widely recognised as the years go by. Not long ago a sum of £500, left by the late Mr. Hector Sassoon for the benefit of unmarried mothers and their children, was allocated by the executors to the Council as the most suitable national organisation to deal with it. This fund made it possible to pay for the third year a retaining fee for a bed and cot in a Church Army hostel, to make grants towards maintenance in a home or hostel, and to send a number of tired mothers with their babies to the seaside for a short holiday. The Council is specially interested in legal reforms affecting children born out of wedlock, and it was a disappointment that the Legitimacy Bill again failed for lack of time in the House of Commons. The help of a good friend was lost on Captain G. E. W. Bowyer's appointment as Government Whip, in which position he is unable to take any active part in the Council's parliamentary work. Captain A. V. Cazalet has now undertaken to watch its interests in the House of Commons. Evidence was given by the hon. solicitor, Mr. Warden Gowing, before the Poor Persons' Legal Aid Committee, to press the need for legal aid to unmarried mothers in affiliation cases, and information was collected in connexion with health insurance and the payment of maternity and sickness benefit to unmarried mothers. The case committee registered 765 new cases during the year ended May 31st, 1926, this being 128 more than in the previous twelvemonth. An inquiry into the expenditure in residential homes was carried out by the consultative committee on homes and hostels. The Council has made efforts to forge links with similar organisations in other countries; it was represented at the first international congress on child welfare, held in Geneva, and on a special committee of the British Auxiliary Societies of the International Woman Suffrage Alliance, meetings of which were held in Paris. One of the sessions of the fourth English-speaking Conference was arranged by the Council, when the subject chosen for discussion was "The Churches and the Child"; two conferences were held at Carnegie House, on "Infant Mortality of Illegitimate Children, and Some Methods of Coöperation by which it might be further reduced," and "Coöperation between District Nursing Associations and Rescue Organisations in dealing with Unmarried Mothers." The general secretary of the Council is Miss Susan Musson, at 117, Piccadilly, London, W. 1.

MEDICAL ADDRESSES.

Mr. Alfred Rose, of the Addressing Company, Ltd., 56, Chancery-lane, W.C. 2, has been to the trouble of preparing a complete set of medical stencils and of keeping them scrupulously up to date by reference to examination lists, obituary notices, calendars, and so forth. The result is that the company is ready at any time to provide a set of envelopes addressed to all the medical men and women on the Medical Register, or to some selected group of these, such as practitioners in Scotland, or Canada, medical women, or Fellows of one or other Royal College. The point is made that every medical man and woman has been addressed in strict accordance with professional etiquette and with the chief degrees or qualifications, continually corrected as necessary. The list contains upwards of 50,000 names, carrying the practitioner's date of registration which can be printed with the address or deleted as required. Card indexes can also be prepared from the same stencils, and so sure is the compiler of the accuracy of the list that he offers to refund postage on every envelope sent with his stencil to any address in the United Kingdom and returned as undeliverable. The charge for straight addressing from the stencils is 12*s.* 6*d.* per thousand, quotation being offered for special lists or selection.

SPECTROSCOPY OF X RAYS AND ULTRA-VIOLET RADIATION.

WE have received from Messrs. Adam Hilger, Ltd., two brochures dealing with spectrometers and spectroscopes. One contains the description of three X ray spectrometers, which are arranged not only for determinations of X ray wave-lengths, but also of the space lattice structure of crystals and powders. These will be of considerable interest to those engaged in radiological work. The other gives a description of a simple ultra-violet spectroscope, which has been designed particularly for investigation of the constitution of the radiations from the ultra-violet lamps used in the practice of light therapy, but forms also a useful instrument for physical and other laboratories. It has quartz lenses and prism, with a fluorescent screen on which the ultra-violet spectrum can be seen. Above this screen is a boldly engraved wave-length scale which serves to denote the position which the radiations occupy in the spectrum. The whole instrument is in constant adjustment, and requires no further manipulation than to direct its slit at the light source. A suitable cloth is provided, with which the back of the instrument and the observer's head may be covered, to facilitate observation by excluding stray light from the fluorescent screen. On covering the head with the cloth provided it is seen that, besides the visible spectrum on the narrow whitened strip at the right-hand end of the fluorescent screen, there are a number of bands of a green hue appearing to the left of this. These correspond to the ultra-violet radiations from the lamp; their position in the spectrum can be determined by reference to the small scale just above them. In this scale the enumeration is in hundreds of Angstrom units. Thus 23 corresponds to 2300 A. Possessing data for the relative values of various radiations in terms of therapeutic effect, it is thus possible to obtain a rapid and accurate estimate of the value of the light source for treatment work. The usefulness of this instrument in testing the absorption of protective windows and goggles, and in observing the ranges of transmission of filters and arc protectors will be readily seen. The necessity of checking the protective value of goggles has been emphasised in a paper by B. D. H. Watters in THE LANCET (1925, ii., 495).

Messrs. Allen and Hanburys announce that for the convenience of prescribers the morphine content of Liquor Opii Sedativus (Battley) has been increased from 1·5 to 1·8 per cent. so that each fluid drachm now contains 1 gr. morphine. The dose is thus reduced from 5–15 ℥. to 5–10 ℥.

COLONIAL HEALTH REPORTS.

BARBADOS.

BARBADOS, the most easterly of the West Indian islands, is a little more than half the size of Anglesey. In a report by Mr. J. B. Howell, Acting Colonial Secretary for the year 1924–25, it is stated that the population of the colony on Dec. 31st, 1924, was estimated to be 159,499, but as this estimate depends on emigration and immigration figures, which experience has shown to be often seriously inaccurate, not much reliance can be placed upon it. According to the census of 1921 the black population numbered 111,677; the number of whites being 10,429, and of mixed 34,216. The birth-rate during 1924 was 32·91 per 1000, and the death-rate 29·54. The percentage of illegitimate births was 68·24. Up to the end of 1924 no registration of the causes of death was available, but from Jan. 1st, 1925, a Registration of Deaths Act came into force, and in the future it will be possible to give information as to the principal causes of death. The number of infant deaths per 1000 births in 1924 was 298, as compared with 220 in 1920, 401 in 1921, 187 in 1922, and 371 in 1923. Barbados enjoys natural and climatic advantages from a health standpoint such as can scarcely be found in any other tropical place. Malaria is unknown, there are no extremes of heat or cold, the soil is well drained, and the water-supply very good; it is, moreover, constantly swept by the trade winds. In these circumstances it is an unusually healthy place of residence for all who are able to secure themselves freedom from insanitary surroundings. Enteric fever and dysentery are, however, unfortunately common. The number of cases of enteric notified during the last five years has been: 1920, 1012; 1921, 3070; 1922, 1084; 1923, 735; 1924, 762. The ordinary type of enteric fever cases is of a mild character. Proposals for a comprehensive review of the system of public health organisation have been placed before the Legislature by the Government at the suggestion of the Secretary of State. The question is one which is full of more than usual difficulty owing to the density of population and existence of vested rights, but the high and fluctuating death-rate, combined with undue prevalence of enteric fever, indicates unmistakably that improved sanitary methods are an urgent need. Apart from the conditions referred to the island is exceptionally healthy and remarkably free from epidemic disease. A venereal disease clinic, established at the General Hospital in 1922, has been attended by steadily increasing numbers. Subsidiary clinics in other parts of the island are much needed. The treatment of inmates of the Leper Asylum with ethyl esters of chaulmoogra oil has been continued with very hopeful results in a number of less advanced cases. Four cases were discharged as cured during the year, and there are at the present time several cases waiting the holding of medical boards to decide whether they can be discharged. All cases that are discharged are required to show themselves to the medical officer of the asylum every three months with a view to his ascertaining whether there has been any return of the trouble. In June, 1924, a riot occurred in the Leper Asylum, when some of the inmates assaulted and beat the superintendent, who had been recently appointed to improve the discipline of the institution. The police had to intervene and the ringleaders were convicted and removed to the Government gaol where they were specially segregated. The majority of the inmates sympathised with the superintendent, and on his return to duty with changes in his staff he has had no trouble in enforcing discipline, and the institution is now in a quiet and satisfactory condition.

BASUTOLAND.

This native territory in South Africa has an area of 11,716 square miles; the altitude varies from 5000 ft. to 11,000 ft. above sea-level, and the climate is, on the whole, healthy. The census of 1921 showed a population of 495,937 natives, 1603 whites, 1069 coloured, and 172 Asiatics. Mr. R. B. Smith, Government Secretary, in his report for 1925, states that during the year 59,295 patients were treated at the Government dispensaries, in addition to 2221 in-patients in the hospitals of Maseru, Leribe, Mafeteng, Mohale's Hock, and Quthing. 2148 operations were performed in 1925. It is hoped to have the new hospital at Qacha's Nek in full working order this year.

The general health of the territory has been very good. Typhus fever, which has been endemic since 1917, has almost disappeared, only 51 cases with four deaths being reported in 1925, as compared with 556 cases and 41 deaths in 1924, and 958 cases with 120 deaths in 1923. This gratifying result in due to the natives appreciating the cause of the disease and taking necessary precautions. The epidemic of small-pox in the centre of the country, which was reported last year, was got well in hand. 26,632 persons were vaccinated. Influenza and dysentery were responsible for 589 and 130 cases respectively, and were of mild type. The free treatment of syphilis has been continued and the number availing themselves of the privilege is increasing every year. Certain European missionaries who live in remote parts of the territory have been given a supply of the remedies for distribution in these areas and with excellent results. The sanitary condition of the various Government reserves has been very much improved by the provision of latrines, &c., for the use of the native inhabitants. Outside the reserves it is not possible to do much as yet except in the way of instruction in simple hygiene when opportunity offers at the dispensaries. On Dec. 31st the numbers of inmates at the Leper Settlement were—males 228, females 233, total 461. Except for minor fluctuations throughout the year the population was stationary. The cases of desertion were considerably more numerous in 1925 than in previous years, and, paradoxical as it may seem, the increase was due to greater prosperity. Most of the desertions occurred immediately after the inmates had been paid for their exceptionally large crop of maize, and it is presumed the less provident went out to spend the money. It is satisfactory to note that of those previously discharged as cases of arrest of the disease only two—one male and one female—had to be readmitted as recurrences, and one female had to be readmitted on account of the lack of proper care outside. The general health of the institution has been good and there was particular freedom from epidemic disease.

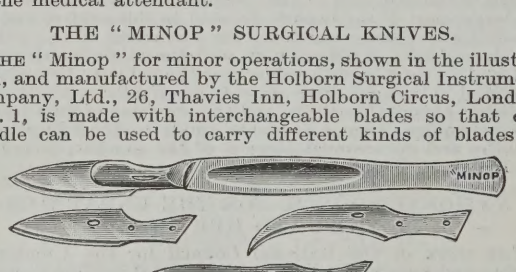
The intensive treatment for leprosy still continues to be rigorously pushed with more or less gratifying results. Dr. Eric Slack, the medical officer of the settlement, went to India towards the end of the year for the purpose of studying the disease there and at the Calcutta centre for leprosy research. Much is hoped from his visit in the way of improved treatment. The farm in connexion with the settlement produced excellent crops of maize, oat forage, hay, ensilage, &c., and the dairy provided 13,680 gallons of milk. Carrots and Swedish turnips were sown for the use of the lepers, who ate them raw for their vitamin content. These raw vegetables had an excellent antiscorbutic effect and rendered the purchase of oranges unnecessary.

ZORBO JOINT JACKETS.

WE have received from Messrs. Robert Bailey and Son, Ltd., Marriott-street Mills, Stockport, samples of "Zorbo" joint jackets which are designed for use in the treatment of sciatica and kindred ailments. They are made of a layer of cotton-wool sandwiched between gauze, and are shaped to fit the chest and back, the shoulder, elbow, wrist, knee, and groin. These dressings are kept in position by means of tapes and buckles and they readily absorb and retain any kind of liniment prescribed by the physician. They promise to be a comfort to the patient and a convenience to the medical attendant.

THE "MINOP" SURGICAL KNIVES.

THE "Minop" for minor operations, shown in the illustration, and manufactured by the Holborn Surgical Instrument Company, Ltd., 26, Thavies Inn, Holborn Circus, London, E.C. 1, is made with interchangeable blades so that one handle can be used to carry different kinds of blades as



may be required. Each blade is pierced with three holes, two of which engage corresponding pins in the handle, while the third hole receives the stud of a lever clamp which securely holds the blade in position. A new blade can be fixed to a handle in a few seconds, and one great advantage of the arrangement is that a sharp knife can always be available. The blades are made of cold rolled Sheffield steel and these are hardened, polished, ground, and set by hand. Metal or leatherette pouches to carry one handle and six blades can be supplied by the company as well as tubular carriers with rack for carrying the handle and blades sterilised in alcohol.

PINE OIL PREPARATIONS.

Messrs. Roberts and Co., wholesale pharmacists, 76, New Bond-street, have sent us specimens of two preparations of pine oil, "Pinolac" and "Pine Needle Spirit." Pinolac is a toilet article intended for use in the bath, the pine oil employed in its preparation being *Oleum pini pumilionis*. Four tablespoonfuls should be added to an ordinary bath of hot water, one tablespoonful to a hip bath, or a teaspoonful to a child's bath. Pine needle spirit is a solution of the same oil in spirit and is intended for vaporising or spraying either in the sick room or the ordinary dwelling-room. Both preparations are pleasant in use.

An Address

ON THE MODERN TREND OF PROPHYLACTIC AND THERAPEUTIC IMMUNISATION AND ITS INTERPRETATION.

Being the Presidential Address delivered to the Section of Pathology of the Royal Society of Medicine on Oct. 19th, 1926,

BY JAMES McINTOSH, M.D. ABERD.,

PROFESSOR OF PATHOLOGY, UNIVERSITY OF LONDON, AND DIRECTOR OF THE BLAND-SUTTON INSTITUTE OF PATHOLOGY, MIDDLESEX HOSPITAL.

ACTIVE immunisation is now recognised as a very definite therapeutic and prophylactic practice in human medicine. Prophylactic vaccination, especially, and particularly in respect to several common infective diseases, has been most thoroughly vindicated by the results achieved. Largely by its means small-pox has become rare, and in well-vaccinated countries has practically disappeared. One of the most striking features in the Medical History of the Great War is the almost complete absence of typhoid fever as compared with the high incidence in former wars.[1] We are not, however, on such sure ground when dealing with therapeutic vaccination, for although in certain conditions very striking results have been obtained, yet in many infections failure must be recorded.

I propose first to make a short review of the literature of the subject in order that the main steps by which the process has advanced may be appreciated

PROPHYLACTIC IMMUNISATION.

It was known even in ancient times that a previous attack of an infective disease may render the individual resistant or immune to a second attack; this was the reason for the wilful exposure of children to infection and even to the actual inoculation of infective material. It is to Jenner, however, that the actual discovery of prophylactic immunisation is usually accredited. The earlier workers on this subject all sought to obtain a modified and less virulent virus. Thus in variolisation the introduction of variolous material under the skin seemed to reduce the virulence of the virus and to produce a less severe attack of the disease. Jenner, being familiar with the old Gloucestershire belief that an attack of cow-pox rendered man immune to small-pox, proved in his brilliant experiments the truth of this idea,[2] as a result of which experiments vaccination against small-pox gradually became general over the whole civilised world. It is now known that the virus of small-pox can be attenuated by passage through animals, but whether Jenner used a true cow-pox or only a modified small-pox will never be known, nor does it matter greatly. At the present time it is probable that most strains of calf lymph are variolous in origin and as such are attenuated viruses.

Pasteur and his collaborators expanded the idea of Jenner and applied it to other infections, both human and animal.

For many years it was firmly believed that the use of a living but attenuated virus was essential to the production of a good prophylactic immunity, which of course greatly restricted its application to human medicine. Gradually, however, this belief has broken down; in the 'nineties Haffkine [3] with his plague vaccine, and Wright [4] with his typhoid vaccine, broke completely away from this idea and used dead instead of living virus. Previous to Wright's work on typhoid fever attempts to induce immunity by inoculations of dead bacteria had been merely tentative and incomplete. It is chiefly to Wright, therefore, that we owe the knowledge that killed cultures provide an efficient means of producing immunity.

The success of prophylactic vaccination against typhoid fever has already been noticed, but it is equally successful against many other infections, including dysentery, cholera, plague, and pneumonia. During the past few years we have seen attempts to simplify the prophylactic injection still further by employing, where possible, simple bacterial products, toxoids, and even aggressins, as in the prophylactic inoculation against diphtheria,[5] scarlet fever,[6] and other infections. The toxin may be modified by the addition of antitoxin or chemical substances. Thus we see that the general trend of medical progress has been to drop the use of a living virus for the dead virus or for some of its products. In immunisation against rabies, virus killed by heat, carbolic acid, ether, &c., have in many institutes replaced the original dried cord method of Pasteur.[7] There is now only one human disease—i.e., small-pox—in which the injection of the living virus is still widely used to procure an immunity. Apparently the Jennerian method is still employed for want of a more reliable one, or is it that the prophylaxis of this particular disease has been so bound down to a fixed procedure that stagnation has followed? Scientifically, it cannot be disputed that from every point of view the injection of virus capable of multiplying in the body of the individual is bad. When multiplication of the virus occurs, then there is no possibility of estimating the dose to which the patient has been subjected. Thus the effect cannot be controlled, and in susceptible individuals this may lead to unforeseen results. It can, of course, be argued on statistical grounds that the likelihood of bad effects after small-pox vaccination is infinitesimal and not worth consideration; but is this really so? It has recently been shown that nervous disabilities (meningo-encephalomyelitis, &c.) may follow vaccination, either as a direct effect or as a sequel to the lowering of the general resistance of the body.[8] From time to time there have been attempts to reintroduce the use of an attenuated living virus as a prophylactic measure in certain other human diseases; particularly is this true in regard to tuberculosis.[9] This I am sure is an innovation which should be rigorously opposed and regarded as a retrograde step; who knows for how long an attenuated bacillus can lie dormant, and then assume its former virulence?

THERAPEUTIC IMMUNISATION.

For the introduction of bacterial immunisation as a curative measure we are indebted to Wright [10] and his collaborators. This form of vaccine therapy is, however, really a development of prophylactic immunisation, but I think that most of you will agree that it has not proved so successful. Once it was hoped that vaccine treatment controlled by opsonin estimations would give therapeutic success rivalling the results of prophylactic immunisation. This hope has been disappointed.

At the outset the originators of this form of therapy insisted on the specificity of the reaction and emphasised the use of specific vaccines. At the present moment there is a tendency for the pendulum to swing the other way, and it is said that there is nothing in this vaunted specificity. Let us analyse this contention under the heading of Non-specific Therapy.

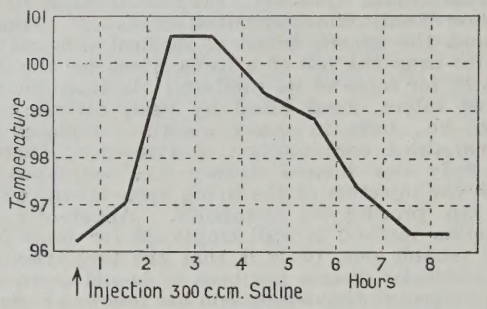
Non-specific Bacterial Therapy.

As I have just pointed out, Wright's original vaccine therapy is based on the principles of strict specificity. But it was frequently observed that rapid improvement followed almost immediately on the injection of a single dose of vaccine, a fact which could not be explained on any of the known phenomena of immunity. This was first noted as long ago as 1893 when Fränkel treated cases of typhoid fever with typhoid vaccine,[11] and Rumpf with *B. pyocyaneous* vaccine.[12]

It is now recognised that other substances, particularly of a proteid nature or origin, can bring about similar phenomena. It would appear that a stimulus is liable to follow on the injection of any substance

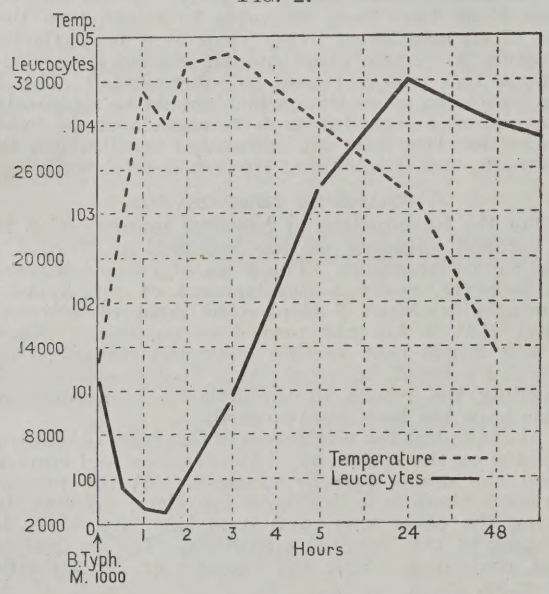
which might be regarded as a foreign proteid. My own attention was first drawn to this reaction when investigating with Dr. P. Fildes the causation of saline fever in relation to salvarsan therapy. In 1912 Dr. Fildes and I noted that the rapid healing of leg ulcers, chronic eczema, &c., frequently took place after an injection of what we then believed to

FIG. 1.



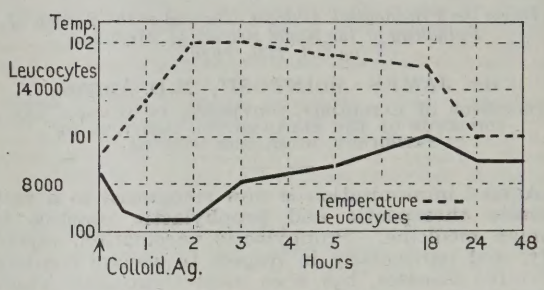
be normal saline.[13] Subsequent investigation demonstrated that saline prepared from ordinary distilled water contained large numbers of dead bacteria—bacteria which are able to grow in distilled water. The injection of such saline intravenously gave rise to considerable reaction on the part of the patient, which we may now regard as protein shock. Generally within half an hour of the injection the patient manifested a rigor followed by a rise of temperature of from 2–3° C., with headache, nausea, or vomiting, and a rapid pulse. The temperature reached its maximum in about three hours' time and then,

FIG. 2.



accompanied by sweating, it slowly fell to normal. In about eight hours' time the patient's condition was again normal, and as already mentioned, the healing of various skin lesions was greatly stimulated. At the present time a considerable amount of success has followed the application of non-specific proteid therapy in such disorders as chronic ulcers, chronic eczema, and rheumatoid arthritis. This line of treatment must also be regarded as a direct development of specific vaccine therapy. The dosage must be sufficiently high to produce a well-marked tissue response, which is apparently preceded by a temporary depression of the defensive mechanism of the body. That large doses of vaccine have this latter effect was well known to Wright, who noted the depression of the opsonic index—termed by him the negative phase. It was undoubtedly the fear of producing this negative phase that prevented the use of larger doses of vaccine, and who is bold enough to say that a more heroic dosage might not have given a better therapeutic result—at any rate in the subacute or chronic infections? We know that

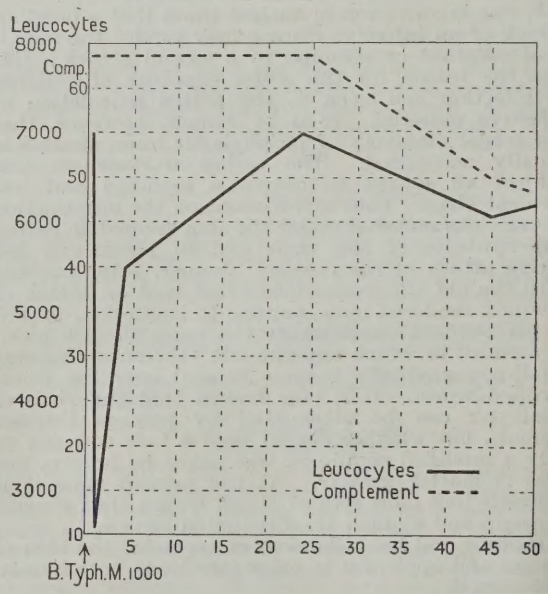
FIG. 3.



although the smaller dose may produce immune bodies it does not always cure the patient. The application of large doses of vaccine to those conditions, such as tuberculosis, where there is a hypersensitiveness to the antigen, is inadmissible on account of the intense reaction which is liable to follow.

When used in larger dosages, specific vaccines produce the typical protein shock of non-specific therapy. The general consensus of opinion seems to be that non-specific or protein shock therapy has come to stay, since in many subacute and chronic

FIG. 4.



infections it has given striking therapeutic results. The effect, as already indicated, is mainly due to the stimulating effects of a foreign proteid or proteid derivative, and the curative effects of such remedies as normal horse serum, Coley's fluid in sarcomata, or a concurrent infection, are all attributable to the same phenomenon; may it not be that some of the effects of colloidal lead in malignant disease are of much the same nature? At the present moment it would appear that the success attained by non-specific therapy has reacted against the use of specific vaccines, and there has followed in some quarters a tendency to minimise the old belief in the value of specificity. But from a scientific point of view this is quite erroneous, as the specific vaccine can cause

both the specific and non-specific reactions, so that by its use a double effect is produced.

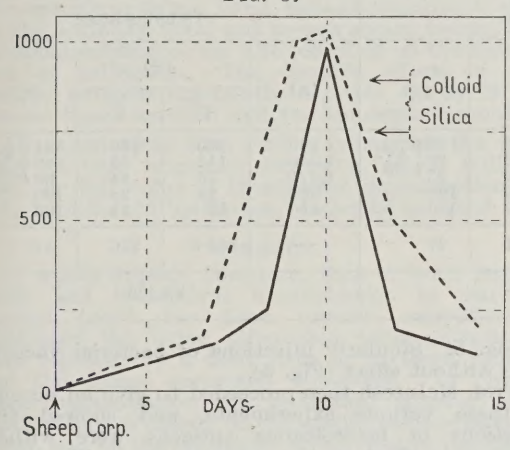
THE MECHANISM OF BACTERIAL IMMUNISATION.

This now brings us to the second part of my address—namely, the nature of these specific and non-specific reactions with which I have just dealt.

Specific Immunisation.

With regard to specific immunisation, immunologists now recognise that resistance to infection following the use of vaccines depends mainly on two factors: (1) The production of specific antibodies. (2) The sensitisation (allergie) of the tissues to the virus. For instance, after antityphoid vaccination antibodies can be demonstrated in the serum for

FIG. 5.



several years afterwards, and even after these can no longer be demonstrated the tissues are still sensitised, as shown by the rapidity with which antibodies can be produced after an injection of antityphoid vaccine.

Dr. L. E. H. Whitby, working in my laboratory, found that antibodies (agglutinins) were readily demonstrated several years after a prophylactic antityphoid inoculation.

Non-specific Therapy.

In spite of a considerable amount of research work into the phenomena of non-specific vaccine therapy, the answers obtained have been rather indecisive. In an indefinite sort of way the effect is accredited to leucocytic action, to an increased flow of blood and lymph, to antiferments, antibodies, phagocytosis, &c. One very definite fact, however, is established—namely, that in most instances the injection is followed by a leucocytosis. As a series of observations on antibody production, which I made quite recently in conjunction with Mr. A. N. Kingsbury, and a later unpublished series made with Dr. Whitby, have some bearing on the explanation of this reaction, I propose to give some account of them here. The phenomena observed may be readily grouped under three headings: (1) General tissue reaction. (2) Leucocyte response. (3) Immunity or antibody response.

The *general tissue response* is apparently dependent on the pyrogenetic properties of the foreign (bacterial, &c.) proteid, as we found was the case in saline fever. This reaction, I think, must be regarded as a process identical with that which occurs in the fever which accompanies a natural infection. Fever, of course, is now regarded as part of a protective process and not to be suppressed, as was the practice at one time. During a fever response the general metabolism is increased, circulation quickened, and the flow of lymph is increased. In this way there is an increased flow of all the protective substances through the tissues of the body, together with an increased rate of removal of waste and such like substances. The effect in its broadest sense is therefore comparable to the old-fashioned poultice or to a fomentation. Such a reaction alone is bound to stimulate the healing of various lesions.

Fig. 1 shows the temperature curve of saline fever produced by the injection (intravenous) of 300 c.cm. of saline—not made from freshly distilled water.

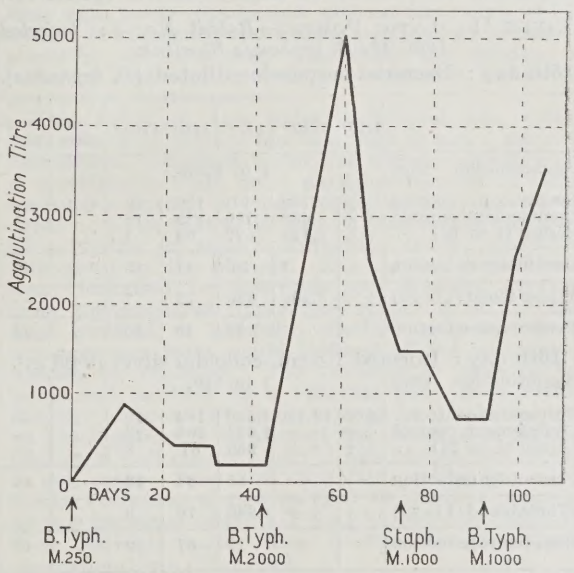
The *leucocyte response* is very definite. It consists, first of all, of a diminution (leucopenia) within an hour of the injection, which is immediately followed by an increase, till within 24 hours there is a well-marked leucocytosis (polynuclears). The effects of a protein shock as obtained in non-specific therapy produced by the intravenous injection of a 1000 million *B. typhosus* vaccine into a rabbit is shown in Fig. 2.

It has been stated that this non-specific effect is mainly the result of the interaction of one type of colloid with another, and it has been claimed that colloidal metals have a similar effect. In our hands the response to the injection of colloidal metals has always been much less than that produced by an organic colloid. Fig. 3 shows the effects of an injection of 0·05 grm. of colloidal silver intravenously injected into a rabbit. Perhaps much of this stimulation is due to the organic colloid used to protect the inorganic colloid. In the case of the guinea-pig the injection of colloidal silver seems at times to have rather a depressing effect, as at the end of seven days the leucocytes had fallen to about one-third of their number, no doubt as the result of the toxic action of colloidal silver.

Antibody Response.

Under this heading the effect on both the natural and immune antibodies has been considered.

FIG. 6.



(*a*) *Natural Antibodies.*—In this connexion certain writers, in particular Jobling and Petersen[14] and others, claim that following an injection of foreign proteid an increase in the ferments and antiferments of the body can be demonstrated. But on their own showing the percentage increase is small and unlikely to be of much value. It seems more probable that the increase observed is in some way or other bound up with the leucocytosis, as the curves given by these writers follow very closely those of the leucocytosis. Estimations of the opsonic index have likewise given very little information. Bulloch and Ledingham, with injections of nuclein, claim a temporary increase of opsonins of 50 to 100 per cent.[15] My own experiments have never shown a very definite increase and in some cases a depression has been noted with bacterial vaccines. On the blood complement, injections of vaccine, apart from a slight depression, had no

distinct effect (Fig. 4). But injections of colloidal silver caused a considerable diminution.

(*b*) *Hæmobactericidal Power.*—The antibactericidal power of the blood after foreign protein injections was estimated by the slide cell method of Wright, Colebrook and Storer.[16] In the first experiment detailed below, a rabbit was injected with 1000 million *Bacillus typhosus* intravenously and staphylococcus used as the implant. Estimates were made before the inoculation, 1 hour, and 18 hours after. The results as calculated from the percentage of surviving colonies show a slight increase (30 per cent.) in the killing power of the blood 18 hours after the injection.

In a series of experiments devised with the idea of elucidating this point, I could find little or no evidence that the specific antibodies were increased after the injection of a heterologous antigen or of an inorganic colloid. The results were similar to those obtained in the chemical stimulation of antibodies.[20] The antibodies tested for were hæmolytic amboceptor, agglutinins and bacteriolysins.

The Effects of Colloidal Silica on the Amboceptor Titre of a Rabbit Immunised against Sheep Corpuscles.

An injection of 1 c.cm. of colloidal silica intravenously gave no appreciable rise of titre, as shown

TABLE I.—*White Rabbit: 1000M. Typhoid Intravenously. Implanted Staphylococcus Aureus.*

(A) Implanted per c.cm. of blood. (B) Number implanted (I) and found (F) per 50 c.cm. blood. (C) Percentage of survivors.

In forming an opinion of the value of these two experiments the considerable technical difficulties must be taken into account; to my mind, after allowing for this, the increase of bactericidal power seems to be outside experimental error.

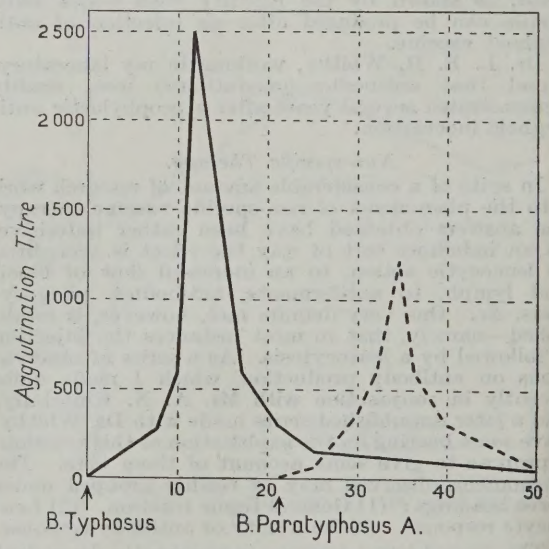
Specific Antibodies.

It has been suggested that one of the main effects of non-specific therapy is produced by a flushing out of the natural and specific antibodies. Hektoen,[17] Conradi, Bieling,[18] and others found that the specific antibodies, agglutinins, &c., were increased after the injection of non-specific antigens. Other observers found no such increase—Baluit, Lüdke,[19] &c. In several of these experiments quoted above I think there is a tendency to lay greater stress on the findings than the results warrant and in such biological tests an increase of even 100 per cent. may not be significant.

in Fig. 5. Similarly injections of bacterial vaccines were without effect (Fig. 6).

[Prof. McIntosh then proceeded to give an account of these various experiments, and showed that injections of heterologous antigens were without appreciable effect on the antibody titre. He showed

FIG. 7.



how one agglutination curve can readily be superimposed on another without interference (Fig. 7). He continued:]

Let us glance back for a moment at what seems a discrepancy between the findings in the bactericidal and hæmobactericidal experiments. The hæmobactericidal results show a slight increase after the injection, while the bactericidal shows no change. In the first place, quite different technique are employed in these two estimations—in the former test the whole blood is used, and in the latter the serum.

If we accept for the sake of argument that the results are correct because they fall in line with the experiments of other workers, then in the whole

blood experiment the leucocytes present are bound to play an important part in the destruction of the test bacteria. After these shock-producing injections the leucocyte-producing tissues are stimulated, and as a result young and vigorous leucocytes are present in greater numbers than before. These leucocytes then exert an increased phagocytic and ferment action. The importance of the leucocyte in this respect has been demonstrated in recent articles by McLean and by Maitland.[21]

I think, therefore, that it may be said that no satisfactory evidence has been brought forward to show that non-specific protein therapy owes its main effects to the stimulation of antibodies—normal or immune. Thus the theory that the substance injected may act as a common antigen or stimulate the tissues which elaborate the antibodies has found no support. Non-specific antigens, I find, have no measurable effect on the antibody titre, and as was shown before, pure chemical substances are without effect on the elaboration of antibodies. The curative effects of non-specific antigens apparently depends chiefly on the general tissue reaction and the leucocyte response.

All experiments have further confirmed the specificity of true immunity reactions, which indicates that the full value of therapeutic immunisation can only be obtained by the use of specific antigens.

SUMMARY.

It would appear, therefore, that in both prophylactic and therapeutic immunisation in man the general trend has been towards simplification. Gradually the living attenuated virus antigen has been replaced by a dead virus or bacterial product, and the dosage accurately controlled. In prophylactic immunisation the protection afforded apparently depends mainly on the specific antibodies elaborated, and on the sensitisation (allergie) of the tissues.

In therapeutic immunisation two factors are at work, a specific and a non-specific. The specific is a typical antibody response, while the non-specific appears to be mainly dependent on a general stimulation of the tissues and leucocytes—in fact, to a process comparable to fever, it is to be noted that in recent years there is a greater tendency to make use of the valuable non-specific response.

Inaugural Address

ON

PRIVATE MEDICAL PRACTICE AND PREVENTIVE MEDICINE.

Given to the Derby Medical Society on Oct. 14th, 1926,

BY SIR ARTHUR NEWSHOLME, K.C.B., M.D., F.R.C.P. LOND.,

LATE PRINCIPAL MEDICAL OFFICER, LOCAL GOVERNMENT BOARD.

IT is not my purpose to mention more than incidentally the official relationship between practitioners in public health and private practitioners. I choose as my more useful task those aspects of the practice of medicine affecting both classes of practitioners, in which active continuous individual collaboration is needed to secure the further advances in national health well within our reach. If in the course of my remarks I appear occasionally didactic, I may claim at least the advantage of experience during seven years in hospital and private work, and during the remainder of a long public health career in organising measures necessitating intimate and almost daily contact with the private practitioner.

Of course, the chief work of the private practitioner is, and for long must continue to be, the guidance of the sick person towards recovery, or the alleviation of his increasing sickness. Except to the callous or the indifferent there must in such work always be a recurrent note of sadness which cannot be escaped; and I know no means for relieving and softening this note more efficacious than the belief that such work—discharged without the hurry which is fatal to efficiency, and carried out with all available scientific aid—not only diminishes the burden of suffering, but also is itself an important means of prevention of disease.

This belief in the wider individual and social importance of private medical work is not a modern conception, though it could not become effective on a considerable scale until medicine became in large measure a branch of exact biological science. There could be no such ideal so long as disease was regarded as a divine or satanic infliction, or as inevitably influenced by the planets. Nor so long as medicine was victimised by doctrines and dogmas, evolved from philosophical hypotheses which were not the final product of carefully checked induction from homogeneous facts, could rational efforts to prevent disease be initiated. The instance in 1853 of an influential petition by a religious body to a Prime Minister of Great Britain to arrange for a national fast on royal authority to prevent the invasion of Asiatic cholera is well known; and it reminds us how recent is our escape from the view that epidemics are a divine visitation, a view as fatal to medical progress as the doctrines which led some doctors to bleed all their patients, and other doctors to give them enormous doses of alcohol.

And yet so long ago as 460 B.C. Hippocrates of Cos had enunciated the truth that disease is a disordered process of nature, and that we must trust to the powers of nature—the *vis medicatrix naturæ*—for controlling it, while aiding this by a judicious medical art. As he said in his "De aere, aquis, et locis":—

"No disease comes from the gods, one more than another, each acknowledging its own natural and manifest cause."

But dogmas based on theoretical considerations governed the centuries, and the doctrines of Galen and Aristotle impeded individual inquiry into the processes of nature. Perhaps our English Sydenham (1624–89) was more instrumental than any other on the clinical side, as was his contemporary William Harvey on the scientific side, in bringing back the minds of people from this attitude to the study of medicine as a branch of natural history. He said:—

"The only means of acquiring a correct knowledge of the fundamental principles of medicine consists in attentive observation of the whole of the phenomena of disease, and vigilant and minute inquiry into the progress and fluctuations of the several symptoms, from which alone the true and natural indications of cure can be deducted."

Subservience to unfounded doctrines was slow in disappearing even after Sydenham's day, but it is by the method thus enunciated by him that the private medical practitioner has made the invaluable contributions to the progress of medicine which we owe to him. The most recent illustration of this is furnished by the life and work of Sir James Mackenzie, whose biography has just been published. He succeeded in freeing our conceptions and preconceptions as to cardiac disease from many errors, in unravelling the mechanism underlying symptoms, and in mastering their prognostic significance, and thus opening the way for more successful treatment of cardiac disease and for prevention of its later consequences. I may refer also to the earliest recorded British example of the application of clinical knowledge to the task of discovering the causation of a disease then very prevalent. You have on the table a copy of the classical contribution read in the theatre of the College of Physicians in London on June 29th, 1767, by Sir George Baker, F.R.S., on the "Cause of the Endemial Colic of Devonshire." Baker was a Devonshire man and was familiar with the symptoms and sequelæ of Devonshire colic. Practising in London he was struck with the resemblance between these symptoms and those of lead poisoning in painters, and on the basis of this similarity conceived the view that the Devonshire colic might owe its origin to lead. This was a preliminary hypothesis based on clinical experience, but he determined not to be among those who in his own words are so obsessed by their favourite theories that they "seldom forget opinions at the bedside, which have been the result of much contemplation at home." He therefore proceeded to make an exhaustive examination of the facts.

On investigation he found that the colic of the cider counties was almost confined to Devon, Hereford and Gloucester in the main escaping. Assuming, as appeared to be clear, that cider caused the colic, evidently the Devonshire cider must differ from that of the two other cider counties. As the clinical symptoms were those of lead poisoning, might not this difference consist in lead?

I need not detail how Baker found that the stone troughs in which the apples were ground were clamped in Devon in a way which included soldering with lead, and the use of lead in the fissures of the troughs; while elsewhere other methods were adopted. Nor need I give the actual analyses of cider, positive and negative, clinching the presence in Devonshire cider of lead,—which clinical knowledge showed was competent to produce the widespread disease,—and its absence from the cider of the other counties. Baker was then able to suggest action, which when adopted demonstrated that the colic associated with cider drinking was not caused by tartar or by the acridity of the drink, but by lead accidentally introduced in the process of manufacture.

The history of preventive medicine, and especially of Listerism, is rich in instances in which, as in the outstanding examples to which I have alluded, life has been prolonged and saved, and disease has been reduced by the accurate, painstaking, and intelligent study of clinical medicine. If I were to mention one chief obstacle to many more triumphs of clinical medicine over disease, it would be that so many practitioners appear to have too many patients, or to be otherwise too busy to be able systematically to think out each case after devoting adequate time to its study, having utilised every available means of diagnosis, whether by consultants or otherwise. When I remember the scandalous way in which at dispensaries and hospitals out-patients were formerly "disposed of," sometimes at the rate of two or three minutes for each patient, I realise that much improvement has occurred; and it is satisfactory to note that even busy practitioners when imbued with a sense of their scientific and moral responsibility find time for more careful work, which is among the most valuable of all contributions to preventive medicine in the present day.

But having claimed for clinical medicine and surgery some of the greatest triumphs in preventive medicine, I must now pass on to consider some examples of still existent evils, which need not continue, if all medical practitioners "pulled their whole weight," and if they had the steady coöperation both of patients and of public health authorities. My illustrations will be taken from three special branches of medical public health work, with the genesis and development of which I have been associated. I refer to the special services of maternity and child hygiene, of tuberculosis, and of venereal diseases. In each of these, although public health authorities are concerned chiefly in the prevention of disease, it is impracticable to draw lines of demarcation between treatment and prevention, and there must be secured, if success is to be complete, whole-hearted collaboration between the official and the private practice of medicine.

THE PRIVATE PRACTITIONER AND THE PREVENTION OF TUBERCULOSIS.

Let me instance first tuberculosis which is still responsible for about 9 per cent. of the deaths registered from all causes in England and Wales, although the death-rate from it is considerably less than half that of 40 years ago. This means that in 1925 there occurred 40,387 deaths from a completely preventable disease, and a vast mass of invalidity and suffering of serious social import.

Why is not a more rapid reduction of this unnecessary drain on our national life being secured? To completely answer this question would prevent me from taking the wider survey proposed in this address. Many of the points which I should otherwise stress are embodied in a contribution to THE LANCET, of May 29th, 1926, on the Present Position of the Tuberculosis Problem.

Here I can only allude briefly to some of the obstacles to more rapid progress. Experience on all sides shows that in a large proportion of the total cases of pulmonary tuberculosis treatment is belated and unsatisfactory. The reasons for this are well known. There is first the unwillingness of patients to come for treatment at an early stage, and much educational work is needed—as in the case of cancer—to secure a general recognition of this point. But it must be agreed that a large number of practitioners—happily a decreasing number—appear to fail to examine their patients carefully, and may continue for weeks or even months treating them for winter cough, for influenza, or for other vague conditions, when an accurate diagnosis might have been made much earlier either by the practitioner himself, or by him in consultation with the bacteriologist (by examination of sputum), or with the tuberculosis officer whose gratuitous services are available in every area throughout Great Britain for this purpose. Not only so, but in special cases the help of the X ray photograph is now commonly accessible at the public expense.

The new regulations as to the relation between panel doctors and the tuberculosis officer may be expected to help; but for insurance and non-insurance patients alike there is needed—as we all increasingly realise—closer coöperation between consultants and

general practitioners, first for the use of available special services, but also for similar and extended provision for others now excluded from these services. The days for single-handed practice have gone by. We all have to admit our need for help from brother practitioners who have skill in a special department of medicine. The appreciation of this need and action upon it does not diminish the importance of the general practitioner, who in the interest of his patient is the assessor and executor of the special knowledge which the expert contributes as a guide in the treatment of the patient.

In no disease more than in tuberculosis is the hygienic work of the private practitioner more important. Is this fact universally appreciated? Do we lay adequate stress on the importance of teaching the patient to cough with his mouth screened, as well as on suitable disposal of sputum? Do we impress upon the patient, and do we adequately realise ourselves, that 14 to 15 per cent. of the total deaths registered from tuberculosis occur at ages under 15 years; that juvenile tuberculosis is concerned also in many deaths registered, for instance, as broncho-pneumonia; and that it is highly probable that infection of human origin in childhood bears a large share in producing adult mortality from pulmonary tuberculosis? Above all, do we realise that this mortality in childhood and youth as well as in adult life results nor merely from circumstances of life favouring effective infection, but is due to repeated and excessive doses of infective material received from adults, who are in our professional charge and to whom we may not even have revealed the nature of their disease? There can be no reasonable doubt that if a simple hygienic code of conduct were rigidly followed by every consumptive patient a much more rapid decline of tuberculosis, especially among children, would follow. For the partial character of the success already secured, not only the medical attendant, but also public health authorities who are slack in their administrative and educational work against tuberculosis, and patients and their relatives who fail to adopt the — often inadequately impressed — precautionary measures which are needed must share the heavy burden of responsibility.

THE PRIVATE PRACTITIONER AND VENEREAL DISEASE.

The case of a patient suffering from a venereal disease furnishes an even more striking example of the intimate interlocking of public and private interests. Appreciative testimony should always be given to the public-spirited attitude of the medical profession in welcoming in 1916 the organisation of clinics for the treatment of venereal disease in every county and county borough at the public expense, and without limitation as to the financial resources of the patient. A remarkable decline of deaths from venereal diseases as compared with pre-war years has been associated with these efforts and with the allied work in which private practitioners and public health and military authorities have coöperated. Great progress has been secured; but these diseases continue to be a serious scourge of humanity, one of the chief causes of premature mortality, one of the largest feeders of our lunatic asylums, and a terrible cause of suffering to innocent women and children.

How can we hasten the diminution of these diseases? If doctors are willing and ready to urge upon each mother and father coming within the scope of their practice the value to health of the training of children's characters on sound psychological lines; and if, with their special knowledge of physiology and pathology, they are prepared to advocate sexual continence, and chastity in the unmarried, and not to permit or even silently sanction the assumption that these are not to be expected from the normal man or woman to whom matrimony is impracticable, then great further progress can be made. The difficulty is that many doctors are not convinced on these points; and that especially we often fail to recognise the social aspect of religion which demands the subordination, in matters affecting the communal welfare, of the personal to the communal interest. Is it not the duty of the doctor as much as of the religious leader or the parent to live up to this ideal? But apart from the supremely important ethical aspect of the venereal problem, there is serious neglect of large branches of preventive work for venereal disease, which are medical in character. May we not profitably consider these sins of omission from the standpoints of private practice?

A not inconsiderable proportion of premature births and of stillbirths are due to syphilitic infection of the fœtus. The medical officer of health receiving returns as to stillbirths finds action beset with difficulties, which if initiated by the family doctor would become easy. In what proportion of cases in which there is reasonable suspicion does the doctor arrange for an examination of the mother's blood, or for examination of fœtal tissues for evidence of syphilis? This examination can be obtained gratuitously. And if this is not done, is not he open to the accusation of possible neglect of the vital welfare of the patients entrusted to him in the conditions of private practice? In asking these questions I fully appreciate the difficulties in doing what is suggested, the obstruction of patients to undue "fussiness," and the courage implied in suggesting the need for such examinations. But are not difficulties meant to be overcome, and can we, or ought we, to have an unreproachful conscience, until or unless we have attempted in every instance to fulfil these duties?

Similar questions arise as regards the medical history and condition of the rest of the family when a husband is under our care for syphilis. Inquiry may show the need for examining these, and are we then justified in refraining from pressing for this to be done?

The position teems with difficulty, and my only desire in asking the preceding questions, which might be expanded did time permit, is to assist towards the more rapid development, in any doctor in whom it may be lacking, of the sense of inherent communal responsibility which is implied in the privilege of family medical practice. In the case of tuberculosis the need for frank medical consultations has been emphasised. This need is even greater for the treatment of both syphilis and gonorrhœa, in which very specialised treatment is demanded. The family doctor to justify his continuing to treat these patients until free from infection must be in a position to treat at least as satisfactorily as the medical officer of a venereal disease clinic.

THE FAMILY DOCTOR AND MATERNAL CARE.

It is not sufficiently appreciated that in the ordinary circumstances of general practice the family doctor is as intimately concerned with the physiological as with the pathological side of life. He is the adviser in the physiological process of pregnancy and parturition and of lactation, including the factors making for mental contentment; he is the trusted counsellor as regards the development of the infant and child; and we may reasonably hope that as his knowledge and competence grow, and as public intelligence increases, he will gain his right position as the guide and counsellor of adults in regard to occupational dangers and to habits of life, especially as to right feeding and drinking.

The word *obstetrician*, as you know, carries with it the meaning of "standing by" to watch the normal process of parturition; and in view of the increasing outspokenness of gynæcologists and others as to the amount of mischief done by premature or possibly entirely unnecessary operative interference with the process of childbirth, it may, I think, be regarded as axiomatic that, except when intervention is urgently needed, a return of the obstetrician to the position of expectant attention is needed in many obstetrical practices. To adopt this course requires courage. The doctor is called upon by the suffering mother and the over-anxious relatives to precipitate matters;

but, given a normal presentation and no excessive delay, the responsible accoucheur temporises by means of a well-chosen sedative. When we know that injury by forceps is a common source of puerperal sepsis and of injury to the infant's brain; and that stillbirths, deaths in early infancy from convulsions, and even feeble-mindedness in surviving infants appear to be especially associated with operative midwifery, the need for careful weighing of the circumstances of each case is sufficiently evident.

The best method of attendance in parturition is secured when the doctor has made it a condition of this attendance that the mother shall have adequate prenatal supervision and care. In fact such medical care is more important than the presence of a doctor at the uncomplicated confinement. At the present time probably nine out of ten mothers do not receive such pre-parturient care. And yet we know that it is important for many reasons. The first is physiological. The subsequent health of her infant is dependent above all on efficient motherhood; and this depends on the mother's health, including the factors making for avoidance of maternal anxiety, care of her teeth, and a dietary which contains anti-scorbutic and antirachitic foods in adequate amount. The early diagnosis and treatment of syphilis and of albuminuria are called for; and the ascertainment of pelvic measurements enables the obstetrician to anticipate complicated parturition and take action as needed.

Should not every medical practitioner be prepared to adopt the rule, demanded by medicine and ethics alike, that apart from emergencies he will only act as accoucheur in cases in which antenatal supervision has been secured? The physiological work on behalf of the mother finds its normal sequel in that affecting the infant. Most of us as practising doctors have relatively few personal opportunities for watching the progress of healthy infants, and this is a handicap in medical work for sick infants. But our knowledge has vastly increased, and has become widely available, through health visitors and others, for mothers everywhere; and the application of this knowledge has borne an important part in the halving of the rate of infant mortality since the present century began. This is especially true as regards the problems of nutrition and the more general problems of efficient motherhood. In this fundamental branch of medicine we are now in a position to become to an extent, never before practicable, *doctors*—i.e., teachers of preventive medicine—and thus raise the general standard of maternal and child health.

THE FAMILY DOCTOR AND THE FEEDING OF CHILDREN.

I pass from the problem of assisting the mother towards increased efficiency in motherhood, in its mental and physical aspects, to take an illustration from the dietetics of children. The interesting report by Dr. H. Cory Mann (H.M. Stationery Office, 1926) shows how an average increase in the course of a year in weight of 3·85 lb. and in height of 1·84 in. in boys having a satisfactory basic diet was increased in boys having a daily extra pint of fresh pasteurised milk to 6·98 lb. and 2·63 in., with the additional result that the boys having the extra milk ration were "obviously more fit than those of the other groups."

Our knowledge of the causation of rickets has been greatly extended, thus rendering it possible to prevent much serious and disabling disease. Although rickets does not figure largely in our national death returns, we know how it may turn the balance against recovery in attacks of measles, whooping-cough, and bronchitis; and we know that it is an important element in favouring the serious chronic catarrhal conditions of children. Hence its prevention should be a chief object of the family doctor; and its prevention is easy. Given a satisfactory diet of mother's milk, from a mother who is being adequately nourished, especially as regards dairy products and fresh vegetables; or given satisfactory cow's milk, from cows fed in the open; and given as a supplementary safeguard the administration of minute doses of cod-liver oil from birth onwards—regulated according to the assimilative power of the infant—there need be no rickets. We know also that daily experience of outdoor air and of the sun's rays can to some extent compensate for deficiencies in the dietary, and like ultra-violet radiation are invaluable both in preventing rickets and in curing this disease when already established.

Will it not be a grave reflection on family medical practice, as well as on the publicity work of public health authorities, if within a generation rickets does not become as rare in this country as typhus fever or hæmophilia?

The importance in another connexion of suppressing rickets is too little recognised. We are all aware and ashamed of the fact that the mortality of women in childbearing has been so little lowered, notwithstanding the attention repeatedly drawn to the subject. For its further reduction closer coöperation between public authorities and practitioners is urgently needed. The provision of an experienced consultant available to any practitioner having charge of a difficult confinement would greatly help, and the new notification of puerperal pyrexia, if private doctors and such a consultant coöperate, should also help. The insistence by the medical practitioner on antenatal supervision of his patient will, as already indicated, be even more valuable.

But the prevention of rickets forms a chief means for lowering puerperal mortality. As I have elsewhere pointed out—

> "A sure way of decreasing childbed mortality is to make cod-liver oil a regular item in the dietary of the mother during the first year of her life."

A contracted pelvis goes along with the pigeon-breasted condition, and with the bowed legs of rickets; and such a contracted pelvis is a chief cause of difficult parturition and the fatal sepsis so often associated with this.

THE SCHOOL MEDICAL SERVICE.

In the preceding remarks I have touched only on a few points relating to the work of the private practitioner bearing on three great services of the State in preventive medicine. Similar remarks might be made on the school medical service, the necessity for the beneficent work of which on a much larger scale than has hitherto been secured might be obviated if antituberculosis work, antisyphilitic work, and the care of mothers and infants, and of the pre-school child were carried out systematically and completely. This can never be fully accomplished, unless in the course of his daily work the family doctor comes to regard himself as an integral part of the entire medical organisation for the service of the public.

HOW THE DIPHTHERIA MORTALITY-RATE MIGHT BE IMPROVED.

I am tempted to give one further illustration of our partial failure to secure the saving of life and the prevention of illness which is well within our reach. Consider the present mortality from diphtheria. In 1925 typhoid fever caused 776 deaths in England and Wales, diphtheria 2774 deaths. The first of these diseases we know is rapidly and steadily declining as the result of improved sanitation and sanitary administration; the second we know—judging by past history—will in a few years cause twice or three times the large number of deaths attributed to it last year. In the past typhoid fever also showed epidemic peaks and troughs in a succession of years. Human effort has almost wiped them out; and we know that human effort can do the same for diphtheria. True, infectious material of respiratory origin is more difficult to inhibit than infectious material discharged from the alimentary canal; but

quite apart from such control, it is well within the power of medical practitioners, given intelligent aid by parents, almost entirely to prevent death by diphtheria. (The occasional occurrence of cases of "lightning" virulence forms only a rare exception to this forecast.) That this is not being done is a grave reflection upon the medical profession and upon the parents of the children whose lives are sacrificed to ignorance and negligence. I am not referring solely to the demonstrated possibilities of immunisation of children against diphtheria. Even apart from such immunisation diphtheria within the next five years might be reduced to the level of typhoid fever as a cause of death. This could be done by the prompt administration of diphtheria antitoxin on the first suspicion of diphtheria. Antitoxin is supplied free by local authorities; how seldom is it used by practitioners before the belated admission of their patients to hospital! The failure to do this is due in part to the fatal practice of suspending diagnosis—and even worse, of suspending treatment—until the result of examination of a swab for Klebs-Löffler bacilli has been ascertained. So much is this the case that it may even be debated whether the routine submission of swabs to examination has not caused more deaths than it has prevented.

An important contributory cause of failure to administer antitoxin promptly is the lack of courage shown by the doctor in not acting on suspicion. He may be accused of mistake, if after giving antitoxin a swab is returned as negative. But his explanation to the parents should remove this difficulty; and even if not, can the feared but usually avoidable loss of prestige of the doctor be placed in the balance against the immense saving of child-life which would be secured if the doctor always systematically administered antitoxin when he first suspected diphtheria?

There remains a large class of cases in which the doctor is sent for late in the disease. In view of the occurrence of such cases, the suggestion has been made that every death from diphtheria, like deaths from anæsthetics, should be made the subject of a quasi-judicial inquiry, as being presumably the result of accident or negligence. What a rapid advance in public opinion and in preventive action would be secured if in any district the local medical profession asked the local authority to organise such inquiries and it were done. Let us think how it might be arranged. The local coroner might make inquiries in all such cases, a physician specially chosen for his professional standing and judicial mind being appointed to assist him. On the result of this preliminary inquiry it would be decided whether a formal inquest was indicated. The publicity of such inquiries would, I am confident, be followed in a very few years by a dramatic decline in the death-rate from diphtheria.

THE FAMILY DOCTOR AS PUBLIC HEALTH OFFICER.

The family doctor, if he attempts to follow out some of the suggestions made in preceding remarks, is, it may be urged, owing to his being paid per attendance, open to the accusation of touting for additional work. This fear appears to me to underestimate the intelligence of the average mother and father. We are, furthermore, proud of being family physicians. Privileges always carry obligations, and the paramount indication is to advise the entire family how to avoid sickness. If we do not feel justified in attempting this task—which on general grounds must appeal to us all—are we not confessing by implication that the conditions under which we now practise medicine in our private work are not those which are most conducive to the welfare of the families whose trusted servants we are, and that some radical reconstruction of these arrangements is indicated?

For the one-third of the total population who are insured under the National Health Insurance Act this hypothetical difficulty only exists when the doctor suggests examination of non-panel members of the family. This is not a serious difficulty. As regards expense, the three great official medical services already indicated give a partial answer; and it may be expected that in time the needed additional facilities for pathological diagnosis, for expert consultations, and for hospital treatment—which are indispensable for a satisfactory medical service—will be made available. These cannot reasonably be expected to be forthcoming on the basis of personal payment for personal services. This becomes increasingly costly with each advance in clinical medicine; and this implies an almost intolerable burden, not only on the wage-earner, but also on a large portion of the middle classes. Much will depend on whether medical practitioners generally are prepared to encourage and promote for their patients coöperative efforts on the basis of prior insurance in virtue of which special services, including hospital treatment and skilled nursing, may always be available when needed. Numerous experiments on an insurance basis are in progress to these ends, especially arrangements ensuring medical consultations and hospital treatment whenever these may be required. It is certain that by promotion of such action, and by taking a responsible part in it, family doctors can, while increasing the efficiency of their own medical attendance, strengthen the tie which exists between them and the families which have placed themselves in their charge.

But my intention in this address is not to describe special methods by which the growing and urgent needs of efficient medical practice can be met, but only to indicate the general principles which emerge. I have said enough, I trust, to make it clear that the progress of the application of preventive medicine depends predominantly on the attitude of the medical profession. It has even been said that doctors constitute a chief obstacle to this progress; but this can only be true in those instances in each community in which there is, for instance, failure to use every available means for prompt diagnosis and for adequate treatment of, say, tuberculosis and syphilis; when the duty of prenatal care for every expectant mother whose name is on a doctor's list has not been realised; and when, for instance again, the doctor fails to fulfil his duty as doctor or teacher, in respect of the prevention of rickets, the avoidance of unhygienic habits, and especially in regard to the consumption of alcoholic drinks. In view of the habit-forming risks involved, the doctor who flippantly and without serious reason prescribes alcoholic drinks to an ailing patient is definitely open to the accusation of anti-social action.

In making the preceding remarks, I have claimed the position of family practitioner as well as of public health officer. As practitioners of both these branches of medicine we can claim that we belong to a noble profession, a calling which, in present circumstances, makes it possible for us to influence the ethical as well as the physical course of a multitude of lives. Indeed, if our common work is to be ideally successful, we must increasingly realise that where preventive medicine has hitherto failed—apart from imperfect knowledge—is in regard to those diseases in which character and conduct are concerned. In his intimate relation with the family advised by him who, so much as the doctor, can influence the people to attain to such conduct in life as will improve personal health, and at the same time safeguard the health of others?

SUGAR AND DISEASE.—At the eleventh annual conference promoted by the Durham County Council in connexion with Health Week at Durham, Dr. F. St. J. Steadman, lecturer on dental diseases of children at the Royal Dental Hospital of London, delivered an address on oral sepsis in relation to the public health. He calculated that if the damage done to a race by alcoholism were multiplied by ten we should get some idea of the injury caused by sugar, which was the beginning of dental trouble. Dr. Steadman expressed his belief that if the bad teeth of the inmates of asylums were extracted an appreciable percentage of those inmates would come out and resume their normal position in life.

THE NATURAL FORMATION OF ACQUIRED ADHESIONS.

BY SIR GEORGE LENTHAL CHEATLE, F.R.C.S. ENG.,
SURGEON TO, AND LECTURER IN SURGERY AT, KING'S COLLEGE HOSPITAL.

THE natural formation of an adhesion between apposed surfaces, denuded of their endothelial covering and in contact with each other, is a simple matter to explain. Such adhesions would be formed by a healing process of first or second intention. By a slight stretching of the new connecting tissue thus formed a slightly elongated adhesion would result in some instances.

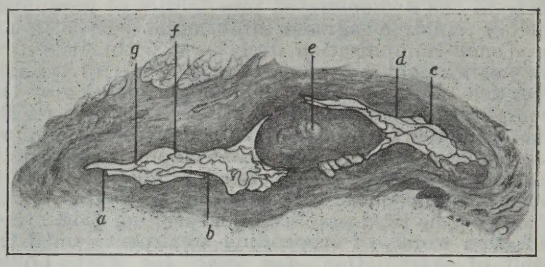
It has always been a more difficult problem for me to account for long, thin adhesions that can so often be observed in serous cavities. It is not practicable to cut whole sections of an abdominal cavity which contains these long adhesions, hence I looked about for a smaller serous cavity that was constantly subjected to traumatic, non-infective inflammation, and I pitched upon the bursa patellæ. I now publish the results of my investigations.

FIG. 1.

An old bursa patellæ which had been constantly subjected to traumatic inflammation over a period of years. It has never suppurated. The bursa has been laid open; a black marker has been inserted behind long adhesions which show excrescences from their surfaces. The base of the bursa shows many excrescences.

Fig. 1 shows a bursa of an old woman whose work necessitated constant kneeling. There never has been suppuration in this bursa. Stretching across its cavity can be seen long, thin adhesions. From the centre of these adhesions appear little outgrowths, the method of formation of which I will subsequently explain. Also, on the exposed surface of the bursa can be seen excrescences of various shapes and sizes. In other parts of this bursa, which are not shown in the picture, but an example of which is seen at *e*, Fig. 2, there were direct adhesions of the nature to which I have already alluded in my opening sentences. Fig. 2 is the microscopical section of a whole bursa patellæ removed from a girl aged 17. This bursa had been inflamed for the first time and was excised ten days after the onset of the attack. The serous and subserous tissues are plicated. They are plicated because these tissues were swollen and increased in size in all dimensions, and, being surrounded by dense connective tissue, they could not expand in all directions. It is to be observed that the cavity of the bursa is filled by a network of fibrin (see D, Fig. 3). Some of the strands of fibrin are attached at their bases (*a* and *b*) to parts of the bursal wall, which are at a long distance from each other. These attachments cannot be explained by any amount of plication.

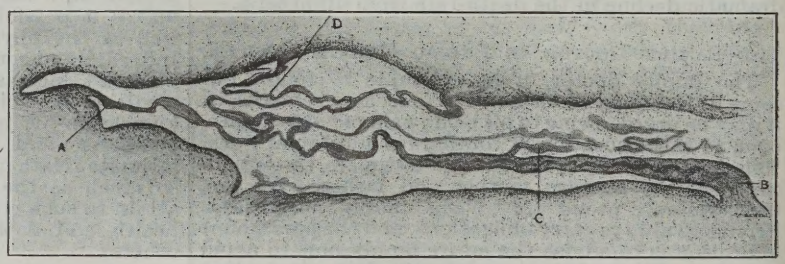
FIG. 2.



The whole section of a bursa excised ten days after the onset of the first attack of inflammation. The surface is seen to be plicated, the interior is filled with a tangled mass of fibrin which is attached at some places, such as *a b*, *c d*, and *f g*, to parts of the surface and in this stage constitute mainly fibrinous adhesions. At *e* will be seen a dense adhesion formed by the *direct method*, when apposed parts have healed while in contact with each other.

What has happened is as follows. The acute traumatic inflammation led to acute inflammation of the parts. Here and there the traumatism rubbed off the endothelium from isolated parts of the surface from which plasma was poured out into the interior of the bursa. This plasma coagulated in the wounds and centre of the cavity, the former giving rise to continuity of attachment of the fibrin in the wounds to the strands of fibrin in the central cavity. At the bases of these attached strands of fibrin two events are to be seen—in Fig. 3. First, the endothelial cells are beginning to grow up the outside surfaces of the strand A and B; secondly, the fibrous tissue (see B) at the bases of the attachment is growing upwards inside this endothelial extension, and taking with it blood-vessels for the nourishment of the new tissues.

FIG. 3.



Represents the microscopical appearances of the adhesions *a b* in Fig. 2. At the base of B will be seen the fibrous tissue spreading up into the strand of fibrin which has also been covered by endothelial cells from the surface of the bursa. At C the organisation of a branch of the adhesion is beginning. The fibrin of this adhesion is gradually being replaced by newly formed connective tissue which is growing into it from the bursal wall (see B). At D can be seen a tangled mass of unorganised fibrin.

As this process continues from two attached bases, the whole strand of fibrin becomes organised into a long adhesion. The excrescences in the middle of the long adhesions, which I pointed out in Fig. 1, are explained by the same process continuing into the tangled parts of the fibrin (see C, Fig. 3). Thus it appears that the

strands of fibrin act in the same way as a hop-pole and forms a scaffolding up which connective tissue grows. The fibrin eventually disappears. The disappearance of an adhesion thus formed probably occurs in the following way. It is known that all young cicatricial tissue is elastic. This elasticity causes pressure upon the newly-formed blood-vessels and diminishes the blood-supply of young adhesions so markedly as to induce their atrophy. Thus they may either disappear, or their bases may remain permanently as excrescences on the surface of the bursal wall. I would term this method in the formation of acquired adhesion the indirect method, and the method with which I opened my article I would describe as the direct method.

The natural formation of acquired adhesions after the occurrence of infective inflammation is a more complicated process than that which occurs after merely a traumatic inflammation. The formation of adhesions after infective inflammation begins with the advent of immunity, when the products of micro-organisms are no longer able to destroy tissues and prevent coagulation of plasma. Upon the acquisition of immunity the organisation of the tangled strands of fibrin begins and continues by the same method as that seen in traumatic adhesions. The main difference in the performance is the delay caused by waiting for the incidence of immunity.

Summary.

The natural formation of acquired adhesions may be due to two methods: 1. The *direct*, in which apposed denuded surfaces in contact with each other heal by first or second intention (see *e*, Fig. 2). 2. The *indirect method*, in which long strands of fibrin become organised by the upgrowth of connective tissue covered by endothelium. They form adventitious connexions between widely separated part of serous cavities (see Figs. 2, 3, 4, and 5).

I must refer the reader to the interesting Hunterian lecture entitled Peritoneal Adhesions, which Mr. Joseph E. Adams delivered in 1913 (vide THE LANCET, 1913, vol. i., p. 663).

AFEBRILE TACHYCARDIA IN EARLY PHTHISIS.

BY ANTHONY DELMEGE, O.B.E. (Mil.), M.R.C.S. ENG., D.P.H.,
ASSISTANT M.O.H. TUBERCULOSIS, WARRINGTON.

THE close attention which has been given during recent years to the study of temperature variations in pulmonary tuberculosis has undoubtedly tended to overshadow its pulse-rate phenomena; the following notes, therefore, may not be without use in drawing attention to their practical importance in adults and especially to the frequent occurrence of long-continued afebrile tachycardia as a sign of activity in early phthisis. By early phthisis I mean definite cases of pulmonary tuberculosis (i.e., sputum-positive cases or those with a history of undoubted hæmoptysis) without extensive signs, marked constitutional disturbance or dyspnœa, and showing no evidence of widespread fibrosis, cardiac disease or displacement, or diffuse bronchitis and emphysema.

The Significance of an Afebrile Tachycardia.

To speak of tachycardia is to assume a normal pulse-rate, hence a preliminary definition of its approximate limits becomes necessary. Starling gives it as 68–72 for those between the ages of 15 and 60. At the same time he lays stress on the wide limits of its normality, and personally I have frequently found an apparent normal of from 58–60 in healthy men. The rate normally shows a diurnal variation of about 10 to 15 beats, rising to a maximum between 4 and 6 P.M. The American National Association in their enumeration of tuberculosis diagnostic standards considers that an average pulse-rate of 85 or more in males and 90 or more in females should be considered abnormal, though in my experience a slower rate than this not infrequently denotes toxæmia if it be associated with an exaggerated diurnal swing. Though one may be misled at times, in actual practice it seems reasonable to take as normal for a given individual the lowest readings persisting for a week or so at a time when all other prognostic criteria are favourable. Such a normal has been assumed in the cases that follow.

The common causes of tachycardia are, of course, eliminated by the usual clinical examination and the use of a careful routine in pulse-taking, but a tachycardia due to anxiety or other depressed emotional state, though it can generally be detected and dealt with by careful questioning and reassurance, often causes difficulty.

On the occurrence then of a persisting afebrile tachycardia in a case of early uncomplicated phthisis we have to decide whether the condition is directly due to the tuberculous toxæmia, or whether it can be set down to one of those other ill-defined and more remote effects of the toxæmia which have been put forward to account for it. Some writers have suggested a small-sized heart, others interstitial neuritis of the vagus, while Pottenger lays great stress on reflex stimulation of the diaphragm and accessory respiratory muscles producing a "deficient inspiratory act," and thus necessitating increased cardiac action to keep up the normal amount of blood delivered to the arteries.

Whatever the accuracy of these theories, in practice the crucial question is whether the condition be a sign of activity in the lesion or not, for if it is, the patient should, of course, remain under treatment until rest has permanently reduced the pulse-rate to normal, while if it is not, there is no object in keeping him in an institution.

Owing to the undue stress formerly laid on the importance of pyrexia as the distinguishing mark of activity, it is still not uncommon to find that an afebrile tachycardia, especially if low and of considerable duration, is unhesitatingly placed in this second category and consequently ignored. Cases such as those quoted below, however, show the not uncommon persistence of an afebrile tachycardia over comparatively long periods of time and emphasise its clinical importance as a sign of activity.

The condition can generally be associated with a definite toxic crisis such as an hæmoptysis or an attack of pleurisy, and can be classified as pre-critical and post-critical according as it precedes or follows this crisis.

Clinically two types of tachycardia are distinguishable: (1) the *swinging* type either an exaggeration of the normal diurnal variation, swinging from about 65 to 80 or 90, or else showing an increased rate throughout with a swing of about 85 to 110; and (2) the *irregular* type, where there is no regular daily variation but the pulse keeps a rough average of 90 or 100. These two types are often, though not always, found in the same tachycardia; indeed, it is quite common after the basic rate has fallen for an increased swing to persist for a considerable time before the condition completely subsides.

As in temperature observations, the morning readings are the more important. This represents what may be conveniently termed the basic rate, the evening reading indicating the degree of irritability or the amplitude of the diurnal swing.

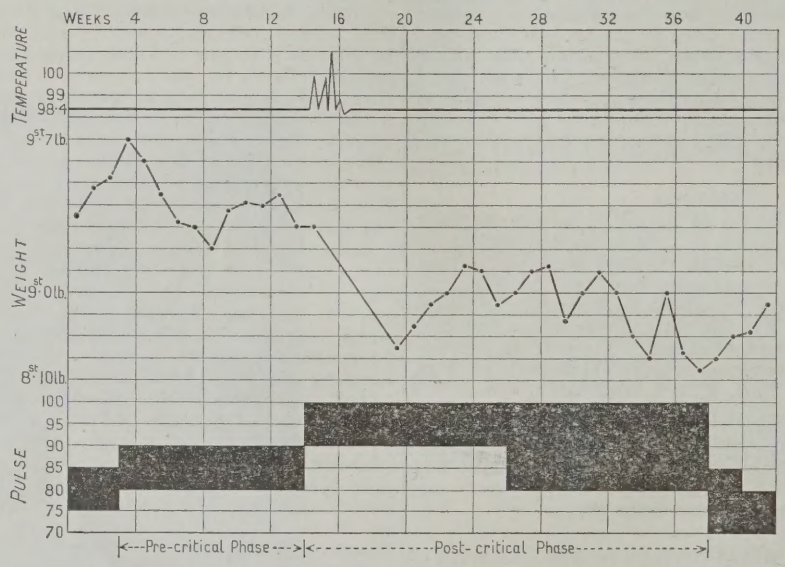
Any toxic condition, such as a mild tonsillitis, or an injection of tuberculin or of a vaccine, may, of course, cause a rise in pulse-rate without a corresponding rise in temperature, and such a tachycardia in which the cause is clear forms a parallel to those of varying duration which occur as part of an undoubted tuberculous toxæmia.

Clinical Illustrations.

One of my patients, a male, aged 22, showed an irregular pre-critical afebrile tachycardia, lasting over a fortnight, and leading to a week's low pyrexia and an hæmoptysis.

In this case a moderate swinging post-critical tachycardia of about nine weeks' duration also followed.

The accompanying diagram illustrates the course of another case and shows the important post-critical tachycardia very clearly. The middle curve is that of the patient's weight, and assuming, as most observers agree, that although increase in weight by no means invariably means improvement, yet loss in weight without change of environment nearly always indicates deterioration, it affords a rough chart of the patient's progress. Below is shown diagrammatically—and, of course, only very approximately—the variations in pulse-note and swing, whilst above is a rough indication of such pyrexia as occurred. The patient, a male, aged 21, had been under treatment for 14 weeks prior to the period shown here. His progress had been quite satisfactory with a weight rising steadily from 8 st. 6 lb. and a pulse swinging consistently between 75 and 85. An hæmoptysis associated with a week's pyrexia indicates the toxic crisis, preceding which is a period of 11 weeks low afebrile tachycardia associated with loss of weight, whilst following is a period of nearly six months high pulse-rate gradually decreasing both in rate and swing.



After seeing a number of these cases it is impossible to avoid the conclusion that in them it is the tachycardia which marks the rise and fall of the toxæmic wave.

Such cases are straightforward enough, but it is often very difficult to come to a speedy conclusion as to the cause when an afebrile tachycardia suddenly begins during treatment or when a patient showing the condition comes under observation for the first time. The evidence furnished by other clinical criteria [1] and the influence of rest and exercise are both of assistance. As regards the former, I have found the facies to be the most reliable aid, but I have not been able to derive much help from the latter owing to the practical difficulties that beset its use as a definite test. When marked the condition reacts to rest in bed, when moderate and subsiding to cautious exercise-grading, any renewal of the tachycardia being taken as an indication for less exercise.

Conclusions.

I have not yet collected sufficient clinical material to warrant any guess at a percentage-figure, but the existence of such cases in early phthisis suggests that just as we find active cases combining pyrexia with a comparatively slow pulse-rate, so also we have these, presumably of the sympatheticotonic type described by Eppinger and Hess, in whom an afebrile tachycardia exists for long periods as almost the sole evidence of activity. Hence, then, while it is, I agree, correct enough strictly speaking to say: "There is no active tuberculosis without pyrexia," an assumption of the contrary "If there is no fever there is no active tuberculosis," or any such statement as "The range of the temperature is the guide to the treatment of pulmonary tuberculosis" [2] seems misleading and not in accordance with the whole of the clinical evidence. On the contrary, the occurrence of this type of case suggests the wisdom of assuming in all cases of early uncomplicated phthisis that, until satisfactory evidence to the contrary is obtained, not only is every afebrile tachycardia a sign of activity, but also that no such case can be considered quiescent so long as it shows a persistently raised pulse-rate, completely apyrexial though its course may have been throughout treatment.

In view of the fact that these cases are almost entirely afebrile, I should like to recur to my opening remark and to put in a plea for more detailed observation of the pulse-rate during the course of early phthisis. In some institutions the pulse seems to be taken once a week only, in others in the case of bed patients only, in many the old type of clinical chart in which the pulse-rate is simply recorded and not charted as a curve, is still in use. Intelligent patients can be taught to take the pulse at least as satisfactorily as the temperature, nor can I think pulse-rate observations in adults as a whole more liable to error, if carefully taken, than those of temperature; the inaccuracies arising from emotional causes — exercise, drugs, &c. —are at any rate no more than those due to atmospheric cold, faulty thermometers, or hurried nurses.

We are all agreed by now that in pulmonary tuberculosis prolonged rest is the key to successful treatment, an opinion strikingly confirmed by the recent radiological work of G. B. Webb,[3] who points out the need of even longer periods of rest than those now usual. The gauging of the requisite amount of rest is in many cases a question of the greatest difficulty for the clinician, and the neglect of any source of information must surely lead to grave errors.

A "BAKERS' BED" AT CROYDON.—The Croydon and District Master Bakers' Association has endowed a bed at Croydon Hospital at a cost of £1000. The hospital is in need of a further 150 beds; there are at present 106.

THE LATE DR. LAWRENCE BARNETT.—The death occurred recently of Dr. Lawrence Barnett, who for more than 25 years had practised in Kilburn. A student of University College Hospital, Dr. Barnett qualified in 1884 and graduated as M.D. Lond. three years later. He became house physician at the hospital and afterwards held appointments at the Victoria Hospital for Children, Chelsea, and the Kilburn and Maida Vale Dispensary. Whilst in practice at Kilburn he was elected president of the Willesden and District Medical Society. Dr. Barnett had lately returned from a holiday and succumbed to a brief attack of pneumonia. He leaves a widow, a son, and a daughter.

TRANSCONDYLAR FRACTURES OF THE HUMERUS IN CHILDREN.

BY F. D. SANER, F.R.C.S. ENG.,
SURGEON (AND SURGEON-IN-CHARGE, FRACTURE DEPARTMENT), ROYAL NORTHERN HOSPITAL.

INJURY to the lower end of the humerus in children is of common occurrence, and in a fracture department the transcondylar fracture ranks next in frequency to injuries of the clavicle and radius and ulna, with but little difference in the actual numbers.

For the most part these injuries to the humerus have been described as separations or fracture separations of the lower humeral epiphysis, but it is rare for the epiphyseal line to be actually involved, or for the epiphysis or part of it to be displaced by itself. The transcondylar fracture is transverse in direction and, as the name implies, occurs generally at the level of the condyles or immediately above them; the line of fracture, which is usually somewhat crescentic with the concavity upwards, passes through the olecranon fossa. There is thus a small fragment of diaphysis which, as a rule, is of about the same depth as the epiphysis. The fracture may be incomplete with no displacement, but in the majority of cases it is complete, and the displacement is severe and typical. The whole forearm with the lower humeral epiphysis and the small fragment of diaphysis is carried backwards with tilting of this fragment, while the lower end of the long upper fragment of the diaphysis is thrust forwards. In the severe case the upper fragment may be driven through the skin on the anterior aspect of the arm; the lower fragment seldom pierces the skin posteriorly, since the tendon of the triceps forms a strong barrier against this. In other cases the displacement of the lower humeral fragment with the forearm is medial, and while this may be the main displacement there is, as a general rule, a varying degree of backward displacement in addition.

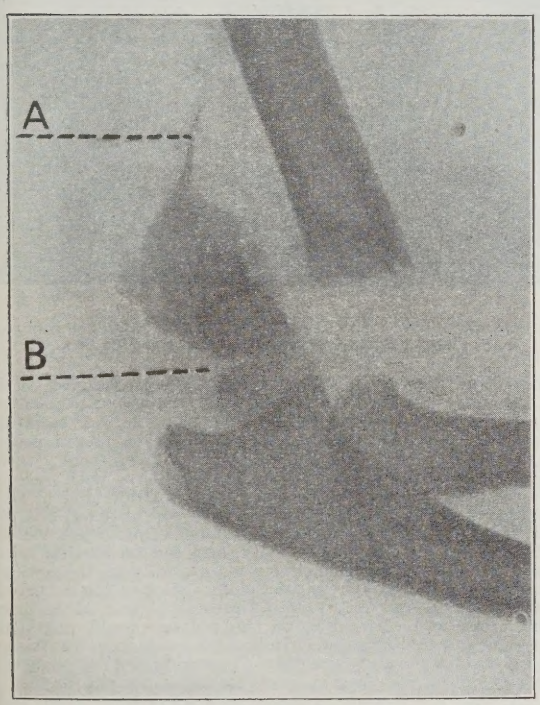
In both types, more especially the former, the periosteum on the back of the humerus is extensively stripped up, while in all cases there is much effusion of blood into the surrounding soft structures, occasionally of such severity as to interfere with the circulation of the hand. On two occasions in my experience gangrene of the fingers has followed such an injury, in one case as a direct result of the tense effusion round the site of fracture, in the other case there was the additional factor that the elbow had been fixed in a flexed position in the presence of much swelling.

The deformity of the elbow is, as a rule, obvious, though the contour of the region may be entirely altered and the bony landmarks obliterated by the swelling from effused blood. An accurate diagnosis of these injuries is impossible without X rays, and radiograms in two planes should be taken at the earliest possible moment and, apart from temporary immobilisation, it is better not to attempt any treatment until a diagnosis has been made. In all injuries in the region of the elbow-joint it is a great help to have control radiograms of the sound elbow for comparison.

Principles of Treatment.

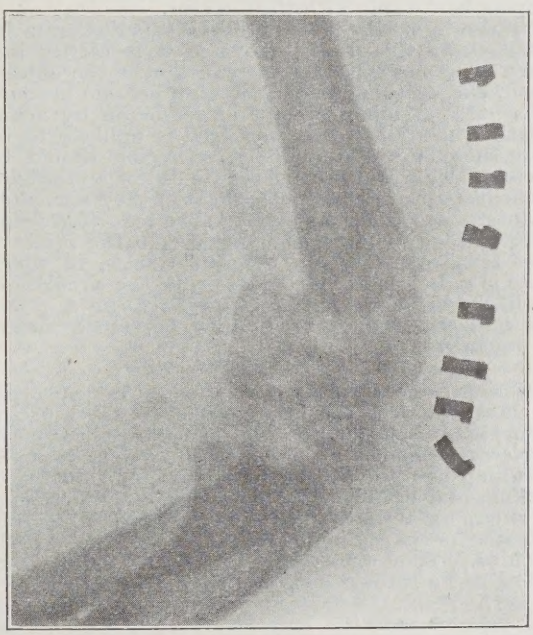
There is probably no region in the body where the attempts of Nature to repair completely a fracture with displaced fragments are so well seen. As shown in the radiogram (Fig. 1), callus is quickly laid down between the fragments, and if left uncorrected the lower end of the shaft is gradually reconstructed, its displaced segment absorbed, and eventually a new diaphysis with its lower end curved backwards is formed (Lane). An arm almost good in function may thus be obtained, but there is always very definite limitation of flexion and extension movements at the elbow. In the same way a lateral displacement, if uncorrected, will be repaired with

FIG. 1.



Boy, aged 8. Transcondylar fracture of left humerus with typical displacement, four weeks after injury.
A, Line of callus formation. B, Epiphyseal line.

FIG. 2.



Same case as Fig. 1 after reduction by open operation.

eventually a valgus or varus deformity at the elbow.

By whatever means, therefore, reduction of these fractures is carried out in the original instance, an accurate alignment must be obtained to guarantee an arm normal in shape and function. Even with a perfect reduction the process of repair is naturally slow; the callus thrown out mechanically obstructs movements for the time, and until this has been absorbed and the grooves and fossæ of the lower end of the humerus remodelled full movements are impossible. This fact emphasises two very important points in the treatment: first, as already mentioned for a somewhat different reason, the necessity for an accurate alignment, since the greater the displacement in any fracture the greater the amount of callus formed; second, the necessity of avoiding undue activity in the after-treatment.

In all cases in which there is a displacement of fractures reduction by manipulation under full anæsthesia should be attempted as soon as possible. With the upper arm held, the hand or wrist is grasped and steady traction exerted with the forearm as fully extended as is possible, and while the traction is maintained the forearm is slowly flexed on the arm, and the position of flexion secured by a strip of adhesive plaster passed round the wrist and upper arm, wool, and bandage. Such movements are carried out to correct the common backward displacement, for the lateral displacement, while traction is maintained, direct pressure is applied to the fragments and afterwards the arm flexed as before.

It is well to emphasise that the position of flexion per se does not accomplish anything, but when the fracture has been reduced it creates traction on the lower humeral fragment and prevents it again slipping backwards with the forearm.

In the majority of fractures reduction can be obtained by this means provided it is carried out early. The main barrier to reduction is the effused blood, and as this organises it may become insuperable. If a genuine attempt at reduction by manipulation has failed, a second trial is unlikely to be more successful, and an open operation should be advised. This should have for its object a clearance of the blood-clot and a replacement of the fragments; no internal fixation is necessary, the reduction being maintained by the flexed position. In the presence of a tense effusion into the soft tissues, in which there is a danger of interference with the circulation, or likely to be with the elbow fixed in a flexed position, an open operation may become a matter of urgency.

After-treatment.

During the succeeding days the gentlest effleurage is employed over the injured area to assist in the absorption of effused products and the circulation of the arm generally. After a week or ten days the arm may be released to a right angle and carried in a sling, and from now onwards gradually increasing *voluntary* movements are encouraged. Vigorous massage or passive movements are to be strictly avoided. They tend only to irritate, cause more callus to be thrown out, and thus defeat their own object. From the first it should be impressed on the parents that the movements at the elbow are likely to be limited for a considerable time, that this is due to the natural course of repair, not a complication, and provided an accurate alignment has been obtained in the first instance an eventual return of perfect function can be assured. The idea of carrying out forceful movements of the elbow under anæsthesia has, it is to be hoped, passed; such a procedure is directly contra-indicated, as already explained, since the limitation is not due to adhesions in the elbow-joint or between surrounding soft structures, but to callus filling the grooves and fossæ of the lower end of the humerus. Occasionally in children who are unable voluntarily to overcome the spasm of their muscles or are fearful of attempting movement slight passive movements may be employed as a means of suggestion that such are possible.

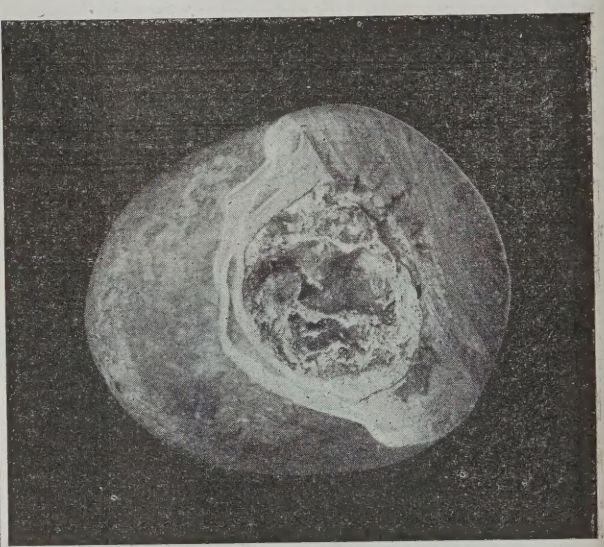
Clinical and Laboratory Notes.

VESICAL CALCULUS WITH PARAFFIN NUCLEUS.

BY ALEX. E. ROCHE, M.B., M.CH., F.R.C.S. ENG.,
CLINICAL ASSISTANT, LATE H.S. AND R.S.O., ST. PETER'S HOSPITAL.

THE interesting account in THE LANCET of July 31st by Dr. Ernest Shaw of a vesical calculus with nucleus of paraffin wax prompts the report of a similar case recently under the care of Mr. Ogier Ward, whom I wish to thank for permission to publish it.

A man, aged 53, was admitted to St. Peter's Hospital on March 9th, 1926, perineal pain being his main trouble. Eight years previously the pain had been experienced on micturition; also slight pain in the penis, and difficulty on micturition. A free interval of two years was followed by a renewal of symptoms, together with retention of urine, such attacks having also occurred subsequently, with



Photograph of stone (actual size), part of it having been removed to display central irregular mass of paraffin wax.

intervals of 1 to 21 days. A symptom very suggestive of the presence of a stone in the bladder was that the patient found it easier to micturate when lying on his side or bending forward. There were straining and delay in commencing the stream, which was occasionally intermittent, with terminal dribbling; and there was urgency, with incontinence if early micturition was not forthcoming. The passage of stones or gravel had never been noticed, but he complained of slime and of the bad smell of his urine, which had been red six years previously, and red on and off ever since, more so on exercise, but not especially at the end of micturition; nor had there been clots. Micturition occurred hourly by day, and six to eight times at night. More than eight years had elapsed since the patient could pass the night without micturating. He had no headaches, but backache now and then for six years; occasionally nausea with the pain, but no vomiting; shivers formerly, but not for years.

Condition on Examination.—The tongue was clean and slightly moist, the patient stating that during the last three to four years it became dry, though thirst was normal. He was observed to bend down, with his head nearly to the floor, in an unsuccessful attempt to micturate. Cystoscopy then revealed four ounces of turbid urine, a very œdematous mucosa, and a free stone, which was felt and heard to grate. The prostate felt normal on rectal examination, while, on bimanual examination, a body was felt above the prostate. On March 10th a stone, too large, hard, and smooth for lithotrity, was removed suprapubically by Mr. Ward. After a period of drainage the patient was discharged healed and well on April 5th.

A report by Dr. H. E. Archer states that the calculus (whose present weight, after about a quarter of it has been removed, is 48 gm., and whose original

weight must therefore have been about 64 gm.) is smooth, irregularly oval, pale brown, and very hard, measuring 5·5 by 4·8 by 3·0 cm., and being made up of an outermost layer consisting of ammonium magnesium phosphate + + +, calcium phosphate + +, and magnesium carbonate (a trace); a middle layer of practically the same constituents, and a central core of hard paraffin, having a melting-point of 54° C. Thus the paraffin would not be liquid at body temperature, but it would be pliable, and one can imagine a portion of moulded candle-guttering reaching the bladder by being propelled by another portion lying in the urethra, and manipulated, directly or indirectly, by the patient, the urethral portion being subsequently withdrawn, or passed with the urine, the intravesical portion being prevented from doing so by becoming coiled, or by otherwise sharing in the general difficulty of escape experienced by foreign bodies in the bladder. Though such may be the method of introduction of paraffin wax into the bladder in some cases, interrogation of the above patient revealed another method in the present case, he affirming that, when aged 17 or 18, he had some difficulty in passing water, due to "a bit of a stricture," and that this was lessened by the passage of a piece of solid rubber, about eight inches long, which is described as being like a catheter, "but without a hole in it," this urethral instrumentation being performed "scores of times," and the instrument, previously greased with warm paraffin wax from a lighted candle, remaining in the urethra for ten minutes at a time. The method described by the patient is probably a correct account of the manner in which the paraffin reached his bladder, small quantities of wax being left there on each occasion, though the motive was almost certainly sexual, not urinary.

One wonders whether foreign bodies, such as paraffin wax, may not compose the nuclei of bladder stones less rarely than has been supposed or reported, and whether their comparative rarity may not be partially explicable by the failure to transect and analyse, where possible, all stones removed from the bladder by lithotomy, and further accounted for by the adoption of the operation of litholapaxy.

A CASE OF GENERAL PARALYSIS WITH BENIGN TERTIAN MALARIA.

BY GEOFFREY T. BAKER, *M.C.*, L.M.S.S.A. LOND.,
ASSISTANT MEDICAL OFFICER, KENT COUNTY MENTAL HOSPITAL, CHARTHAM DOWN, NEAR CANTERBURY.

THE interest in this case would appear to lie in the fact that the patient had malaria of long standing and that general paralysis developed in spite of this, and also that a further severe relapse of malaria in no way hindered the progress of the cerebral condition to a fatal termination.

A man, aged 39, was admitted to the Kent County Mental Hospital on Jan. 18th, 1926, with general paralysis and a history of malaria and heat-stroke. The blood and C.S.F. were taken on Jan. 21st, 1926, and both showed a complete positive Wassermann reaction. The patient was confused, quite disorientated, wet and dirty in habits, much hallucinated, and very restless. By the beginning of April he had quieted down sufficiently for a course of Stärcke treatment to be begun, but before the fourth injection could be given he had again become very restless and troublesome, and the treatment had to be abandoned. There was then little change in his condition until August 1st, when he had two bouts of fever rising to 103° F., with one day intervening, when his temperature was subnormal. The blood was examined and benign tertian malarial parasites were found to be present. Fifteen typical rigors followed with one or two atypical ones, and, as there was no improvement in his mental condition, quinine treatment was commenced. On Sept. 6th the patient died, having previously developed retention of urine and multiple syphilitic sores.

I am indebted to Dr. Abdy Collins, medical superintendent, Chartham, for permission to publish the notes of this case.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DERMATOLOGY.

A MEETING of this Section was held on Oct. 21st, Dr. J. H. SEQUEIRA, the President, being in the chair.

EXHIBITION OF CASES.

Dr. G. B. DOWLING showed a case of lichen nitidus in a woman of 28 who had complained for a year of a papular eruption of various parts of the body, with very slight irritation. Over the knees, elbows, and front of the wrist these became confluent, forming brownish-red patches rather like lichenification. Friction played a part in the production of these areas. Histologically there was characteristic subepidermal infiltration with a giant cell here and there. The erosion from beneath amounted in the confluent areas almost to complete disappearance. He also showed a case of syphilitic macular atrophy in a man of 44 who had had primary syphilis with phagedena 24 years ago, followed in three months by a generalised eruption of raised pink spots. A few months later they assumed their present form—a large number of symmetrical lenticular elevations, round or oval, distributed mainly along the lines of cleavage on the back, chest, abdomen, and shoulders. Some were firm, others soft with wrinkles like cigarette paper. There was a definite resemblance to some cases of Buzzi's disease, which was no more than a macular atrophy, not necessarily due to syphilis.

Dr. H. HALDIN-DAVIS showed two cases of pigmentation. One was argyria in a woman who had taken silver nitrate pills thrice daily for a year 20 years ago and had been in her present state ever since. Argyria was very capricious in its incidence; in another case it had developed after the use of protargol swabs for six weeks; this, however, disappeared in three years. His second case, "pigmentation of unknown origin," corresponded with a type described by Barber as "poikiloderma pigmentare reticularis," although in this instance no atrophy had been noted. He regarded the condition as some sort of vasomotor disturbance, associated with the menstrual trouble of six years' standing.

Dr. PARKES WEBER showed a case of von Recklinghausen's disease which he had presented to the old Dermatological Society in 1905 in its earliest pigmentary "forme fruste." It was now fully developed. His second case was one of pigmentation of the thigh associated with varicose veins and a condition rather like "multiple idiopathic hæmorrhagic sarcoma" (Kaposi). The patient was a fat plethoric Jewess of 47, who last winter developed irregular, raised, rough, purplish patches with much itching. Adjoining these was an irregular area of brown pigmentation which had appeared a month earlier and never itched. The Wassermann was negative. Dr. A. M. H. Gray had examined sections of an excised nodule and thought them strongly suggestive of lichen planus. Sir Jonathan Hutchinson had described lesions resembling "multiple idiopathic hæmorrhagic sarcoma" as occurring in plethoric and gouty individuals. His third case was a boy of 3 with hypoplasia (aplasia) pilorum moniliformis of the scalp, which was rough and in some parts scaly and red, with stumpy hairs. Microscopically the hairs were beaded with alternate constrictions and spindle-like enlargements. Some of the eyebrow and eyelash hairs were similarly affected. The case was typical. Dr. Weber suggested that there might be a series of cases connecting congenital alopecia on the one hand and MacLeod's "ichthyosis follicularis" on the other, with congenital hypoplasia pilorum moniliformis in the middle. This was a congenital condition allied to nævi.

Dr. H. W. BARBER showed a case of lichen spinulosus in a boy of 12. The eruption was first noticed ten

weeks ago on the legs, and later it appeared on the arms, neck, face, and trunk. It consisted of follicular papules, the colour of normal skin or a little red at the base, with a projecting horny spike. This case corresponded with the 14 cases described by Peyri Rocamora in 1922, in which there was always a resistant stomatitis. In this boy there had been a trace of something like perlèche at the angles of the mouth and a few red spots on the mucosa of the cheek. The relationship of lichen spinulosus to folliculitis decalvans and of both to lichen plano-pilaris had to be considered.

Dr. E. GRAHAM LITTLE showed a case of nodular leprosy which he had brought before the Section in May last as one of the most acute cases he had ever seen; a very extensive eruption had appeared within ten days. Instead of returning to the East, as advised, the patient had come under the care of Dr. Hasson, whose treatment had resulted in an amazing improvement. So complete was the involution of the disease that the bacilli could no longer be found in the nose or in the artificial blisters.

Dr. J. HASSON then described his treatment with stock vaccine made from the blisters of many patients.[1] This patient had had 53 injections twice or thrice a week, mostly intravenously, and some subcutaneously. In a fortnight æsthesia had reappeared. After six weeks he was as "cured" as it was possible to pronounce any man cured. Dr. Hasson had now obtained apparent cure in 45 cases.

Dr. GRAHAM LITTLE then drew attention to a large coccus isolated from three different cases, one of glossitis migrans and the others more like a leucoplakia of the lichen planus type. This organism had been grown with great difficulty anaerobically and was unfamiliar to the bacteriologists of St. Mary's Hospital. His third case was one of lupoid infection of the skin following a successful course of electrolysis for removal of hair. There had been no scarring at the time, but the lesion appeared two years later.

Dr. H. MACCORMAC showed a Covent Garden porter, aged 25, who was accustomed to carry loads on his head and who had developed a bald spot very like an ecclesiastical tonsure and with definite lichenisation. The patient assured him that the condition was not uncommon. He proposed to name it "Covent Garden tonsure."

Dr. J. H. T. DAVIES showed a case of lichen planus confined to the mouth.

Prof. C. RASCH, of Copenhagen, then contributed

SOME HISTORICAL AND CLINICAL REMARKS ON THE EFFECT OF LIGHT ON THE SKIN AND SKIN DISEASES.

He began by condemning the attitude of those who regarded clinical medicine as a played-out science; modern medicine rested equally on two supporting pillars—clinical and experimental work. The first observations on the effect of sunlight on the skin were made by Everard Home in the Philosophical Transactions for 1821. Home had exposed the backs of his hands to the sun with a thermometer on each; one was uncovered, the other had a covering of black cloth. The former hand was scorched on each occasion, the latter was unaffected, but its thermometer registered a much higher temperature. He concluded that the black rete mucosum of the negro was a defence against the sun's rays. His experiments were confirmed later by Humphry Davy's brother John. Their experiments entitled them to the honour of the discovery that the power of the sun was due to light and not to heat.

The Effects of Light on Abnormal Skin.

Willan in 1798 had described an "eczema solare," and other sun-produced lesions were noted by Rayer (1835), Bazin (1860), Kaposi (1870), J. Hutchinson (1878), and Veiel (1887). In 1906 Dubreuilh, of Bordeaux, had stated that most of the epitheliomata of the face and so-called senile alterations of the skin were produced by the light of the sun, and his conclusion had been foreshadowed by Robert Bowles in 1893, who had remarked that if the sun's rays would produce sunburn, erythema, and blistering they were clearly capable of producing deep and intractable ulceration of a low and chronic nature. More recently "permanent freckles" had been described by J. H. Sequeira (1911) and "war melanosis" by Riehl (1917). Between some of these conditions there were transition stages; Hutchinson's prurigo, for instance, could not be kept distinct from the polymorphic and eczema-like eruption described by the speaker. He believed, in fact, that all these eruptions should be included under the one term, "chronic polymorphic light dermatitis." Individual skins reacted to the itching caused by light with papular, urticarial, erythematous, or lichenoid lesions, and secondary infections might supervene, and on rare occasions small necroses might represent a transition to the hydroa vacciniformis of Bazin. These light eruptions might be hereditary and were very common among blondes—e.g., in Denmark out of 31,000 patients in five years no less than 230 had a light-lesion. It might be surmised that the itching was the pathogenic factor in the production of a rash.

Hydroa Vacciniforme and Porphyrinuria.

The speaker believed that two diseases were being confused under this name. One was the affection described by Bazin; the other was a special symptom-complex including porphyrinuria, large pemphigus-like blebs on the face, ears, and hands leading to gangrene, and atrophic processes in the fingers reminiscent of scleroderma or Raynaud's disease. This condition was first attributed to light by Prof. McCall Anderson in 1898.[2] Porphyrinuria was not always associated with sensitiveness to light, and the administration of sulphonal and trional did not cause skin trouble. Possibly the real cause of all the symptoms was some unknown endocrine factor. The significance of porphyrinuria in light diseases and the relation of these conditions to epidermolysis bullosa hereditaria needed further investigation. Alcoholism also seemed to be a sensitiser for the development of light rashes.

Other Diseases Connected with Light.

In Denmark they had had two cases each of xeroderma pigmentosum, war melanosis, and colloid degeneration of the skin; pellagra was unknown. The chronic redness and thickness of the skin of the neck described by Jadassohn and Nikolsky was common, as were senile degeneration of elastic tissue and other so-called "senile" lesions.

Light in Other Diseases.

It was an old experience that the rash of small-pox healed without scars if the patient were kept in the dark, and this treatment ought to be used in all cases. Pityriasis simplex was often irritated and was sometimes made eczematous by light. Acute eczema and many kinds of artificial dermatitis tended to become localised in the sites of chronic changes due to light. For instance, sulphur or fur dermatitis might be localised in the sterno-clavicular triangle, although the exciting agent had spread over the whole chest. Rosacea was greatly aggravated by light; cases of this disease could profitably be divided into three groups: (1) rosacea cum acne, curable with sulphur; (2) rosacea cum pityriasi, curable with tar; and (3) rosacea cum acne et pityriasi, curable with sulphur plus tar (ichthyol). Lupus erythematodes might be caused by light and was decidedly aggravated by it: the lesion was often limited by clothing or ornaments. Tuberculosis and light were the most important internal and external causes respectively. The fresh eruptions disappeared rapidly if the patient were put to bed in the dark. Other skin diseases aggravated or caused by light were dermatitis herpetiformis, Besnier's prurigo, purpura, and erythema multiforme

[1] THE LANCET, 1926, i., 234.

[2] British Journal of Dermatology, January.

Skin Disease Improved by Light.

Few skin conditions benefited from light, and the value of the general light bath was usually due to its action on the organism as a whole. Acne vulgaris, secondary syphilitic infections, elephantiasis, and lichen planus might be benefited, and light prevented the development of a papular syphilitic lesion. Even in these cases, however, it seemed that pigmentation played a part and that the curative effect was not purely local.

It was a common mistake to think that as much light as possible was good for all people and all diseases.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A MEETING of this Society was held in Liverpool on Oct. 15th, Mr. W. GOUGH (Leeds), the President, in the chair.

Miss H. M. DUVALL (Liverpool), on behalf of Prof. E. E. GLYNN and herself, described a case of

Rupture of the Bladder during Labour.

The patient was a primigravida aged 29, and, during her pregnancy, had been a regular attendant at the antenatal clinic attached to the hospital. Her pelvic measurements were normal, and so was the urine, which for some time had been tested weekly.

On admission (April 27th) she was at full term; the os was one finger dilated, the head well down in the pelvis, and the position left occipito-anterior. During the next three days she had intermittent labour pains. The membranes ruptured at 6 P.M. on May 1st, and the os was three-quarters dilated at 8 P.M. At 3 A.M. on May 2nd the patient is related to have given a piercing shriek, and complained of acute abdominal pain. The nurse felt the uterus, and there was no contraction, but the patient was rather cold and clammy.

After this the patient became somewhat hysterical, and the house surgeon was sent for at 6.30 A.M. As the labour had been long, and the interest of the child seemed to demand it, low forceps were applied under chloroform anæsthesia, and the patient easily delivered of a living male child weighing 6 lb. 5 oz. There was a perineal tear of the second degree, and this was repaired. The third stage occupied one and a half hours, and the placenta and membranes were delivered by manual expression. The condition of the patient was then considered satisfactory. The patient passed urine voluntarily just before the anæsthetic, and no urine was obtained on the passage of a rubber catheter before the application of the forceps.

Her condition gave rise to no anxiety during the next 24 hours, but as she passed no urine during that time, she was catheterised, and 8 oz. of "smoky" urine, which is said to have contained no blood or albumin, was withdrawn. On the following day she passed 8 oz. of urine voluntarily at 2 A.M., and 6 oz. again at 2 P.M. By the evening she had become very ill,the complexion sallow, the temperature 100·2° F., the pulse rapid and almost imperceptible, and the respirations quickened. The abdomen was much distended and very tympanitic, and there was pain in the left iliac region. The usual restoratives were given, but she was much worse by the next morning, with a frequent brownish-green vomit and incontinence of fæces. She died three days and five hours after delivery.

At a post-mortem examination made seven hours after death the subcutaneous fat of the abdominal wall was found to be fully three to four inches thick, which had hindered accurate diagnosis of the abdominal condition during life. The peritoneal cavity held about six pints of a turbid and slightly blood-stained fluid, smelling strongly of urine and containing large flakes of recent fibrin. The intestines were distended to about double their normal size, and the peritoneal coat was injected. On examining the bladder, a small oval perforation, which would just admit the points of a Spencer-Wells forceps, and the edges of which were gangrenous, was discovered on the posterior surface about midway between the fundus and the utero-vesical reflection, and half an inch from the mid-line. Radiating from the hole were three rents involving the serous and muscular coats, but not the mucous membrane. When the bladder was slit open from the front, the perforation was seen to be surrounded by an area containing numerous small hæmorrhages. Apart from this the lining epithelium appeared to be normal, as were also the ureters and their orifices. The kidneys and other organs showed no evidence of disease. The uterus was uninjured except for a deep right-sided cervical tear.

The cause of death in this case, said Miss Duvall, was undoubtedly rupture of the bladder followed by peritonitis. When and why had this accident occurred? It must be a very unusual one, as after a good deal of search she could only find two cases recorded in which intraperitoneal rupture occurred actually during the course of a full-term labour.[1]

"The wall" of the uterus in the present case, said Miss Duvall, was somewhat thinner than normal; the thickness of the muscular and mucous coats was just over 2 mm., whereas the normal measurement was 6·8 mm. There was no cystitis, the muscle was not diseased, and there was no inflammation. The situation of the lesion made direct injury by the forceps unlikely. The presence of distension at any time during the labour was not shown in the history, but the first stage had been long, and the patient might not have been properly emptying the bladder throughout. The temperature chart was consistent with an ingravescent sepsis. The amount of urine obtained after delivery was only 22 oz. in three days, and it was curious to note that the patient had been able on two and possibly three occasions to pass urine voluntarily, presumably after rupture. In view, however, of the very small leak, this could not be considered an impossibility.

In the opinion of Prof. Glynn and Miss Duvall, all these facts pointed to the rupture having occurred prior to or at the time of delivery, the cause being increased intra-abdominal pressure due to the pains of labour on a bladder probably over-distended, and therefore weakened, but certainly not otherwise diseased.

The PRESIDENT considered that the rupture occurred when the patient cried out.

Prof. BLAIR BELL (Liverpool) thought there was no hysteria about the case, that the smoky urine had been of great significance, and that measurement of the urine would have been of aid in diagnosis.

Dr. J. W. A. HUNTER, with acknowledgment to Dr. W. Fletcher Shaw, gave an account of

A Case of Abdominal Pregnancy.

The patient was aged 30 and was 3-para. She was admitted to St. Mary's Hospital, Manchester, on August 23rd last with the following history.

Her last menstrual period was on March 16th, and was followed by several weeks of irregular bleeding for which she was curetted in one of the outlying hospitals, a diagnosis of incomplete abortion having been made. After curettage the bleeding ceased, and she was sent home, but shortly afterwards she noticed a gradual increase in the size of the abdomen. About the beginning of July she had a sudden attack of acute pain in the abdomen with sudden enlargement of the swelling; accompanying the pain were recurrent attacks of vomiting and faintness. During the six weeks before admission there was progressive abdominal enlargement with increasing tenderness and recurrent attacks of severe abdominal pain often accompanied by vomiting. Six days before admission there was slight loss of blood from the vagina. Beyond these, increasing frequency of micturition and gradually increasing constipation were her only symptoms.

On admission she was rather pale, collapsed, and obviously in considerable pain. Her pulse was small and rapid, the rate varying between 120 and 140, and the temperature was 100° F. Examination of the abdomen showed it to be enlarged to the size of an eight months pregnancy, the tumour extending almost to the ensiform cartilage. The swelling tended to occupy more the left side of the abdomen than the right, and was hard, rather fixed and extremely tender, the whole picture closely resembling that of a concealed accidental hæmorrhage. On palpation it was possible to elicit fluctuation in the upper left portion, but the mass in the right iliac fossa was quite hard and solid. Percussion did not show any dullness in the flanks, and on auscultation no fœtal heart sounds or movements could be heard. Vaginal examination was unsatisfactory on account of the extreme pain and tenderness, but suggested a firm mass continuous with the cervix occupying the lower right quadrant of the abdomen, and a large cystic mass inseparable from it above and to the left.

[1] Jour. Obst. and Gyn., vol. vi., p. 354; and Trans. Obst Soc. Lond., vol. xlix., p. 171.

The diagnosis lay between concealed accidental hæmorrhage and a twisted ovarian cyst complicating early pregnancy. The possibility of an abdominal pregnancy was considered, but rather discounted in view of the previous curettage and absence of other signs.

The patient was kept under observation for 24 hours, but did not improve; in fact, she became rather worse. operation was then decided upon, a diagnosis of twisted ovarian cyst complicating early pregnancy having been made.

On opening the abdomen a large rather thick-walled cyst was seen almost filling the peritoneal cavity, which also contained a large amount of recent fluid blood and old blood-clot. On extending the incision the cyst was seen to arise from the left broad ligament, which had been stretched and lifted up, while the uterus—enlarged to the size of a three months pregnancy—was closely apposed on the right side. On attempting to separate the cyst it was found to be adherent to the abdominal wall in front and to the omentum and small intestine above and behind, and during this separation the anterior wall suddenly gave way and a large quantity of liquor, followed by a living child, came out. The gestation sac was then seen to be composed of a much stretched-out broad ligament anteriorly, while posteriorly it had burrowed under and lifted up the cæcum and mesentery of the small intestine; the right colic artery was running in the wall of the sac. The placenta was hurriedly removed, and the sac packed with gauze and marsupialised. During removal of the placenta there was very little bleeding, but there was considerable hæmorrhage in the abdominal cavity, probably from a torn branch of the right colic artery.

After operation the patient was very collapsed and failed to respond to treatment, dying shortly after return to the ward. The child, weighing 2½ lb., was quite normal and lived for 14 days.

The so-called incomplete abortion, said Dr. Hunter, for which the patient had been curetted was probably an early ectopic gestation; very possibly rupture of the sac into the left broad ligament had occurred during this manipulation. The associated hydramnios almost excused the mistake in diagnosis, for even when the cyst was exposed it was impossible to palpate the fœtus through its walls. To avoid a fatal result had been very difficult in view of the way in which the sac had displaced the mesentery and bowel. Perhaps incision of the sac, emptying of the contents and immediate packing would have given the one chance of a successful result.

Dr. J. H. WILLETT (Liverpool) said that he considered it safer to leave the placenta, though recovery would be tardy.

Dr. D. DOUGAL (Manchester) recalled a case of full-time ectopic pregnancy, in which the placenta was removed and the patient made a good recovery.

Dr. C. P. BRENTNALL (Manchester) described a case of abdominal pregnancy at four months.

Specimens and Cases.

Dr. BRENTNALL showed slides illustrating an endometrioma of the anterior abdominal wall in a woman of 37. The tumour was the size of a filbert and was firmly embedded in the rectus muscle. He said that he had not found any recorded instance of a growth of this kind being situated so far from the uterus. The woman had had no previous operation, and the fact that the ovaries were not adherent suggested that they had not acted as an intermediate host for the spread of the tumour over the peritoneal cavity. There was no chocolate fluid in the tumour and the umbilicus was normal.

Dr. H. LEITH MURRAY (Liverpool) showed a specimen of primary carcinoma of the appendix, emphasising the fact that such a growth might present itself as a very inconspicuous lesion.

The PRESIDENT reported a case of labour obstructed by a diverticulum of the rectum.

Prof. BLAIR BELL (Liverpool) described two cases of bilateral squamous-celled carcinoma of ovaries and peritoneum, subsequent to vaginal hysterectomy for carcinoma of the cervix, and to carcinoma of cervix treated by radium.

Dr. J. W. BRIDE (Manchester) reported two cases of malignant disease in association with genital prolapse.

Reviews and Notices of Books.

SIR JAMES MACKENZIE.

The Beloved Physician, Sir James Mackenzie. A Biography. By R. MCNAIR WILSON. London: John Murray. 1926. Pp. 316. 12*s*.

Dr. Wilson has written a readable biography of one whom he loved as a man and whose genius he admired with whole-hearted enthusiasm; and indeed Mackenzie was one who deserved to inspire these sentiments, for he was a good friend, a most helpful teacher, and one who threw a flood of light upon the dark places.

James Mackenzie, like many of his famous compatriots, came of good Highland farming stock. He was born at Scone and educated first at the Perth Academy, where he wondered, as many at other schools have done, why his teachers set so much value on memory and so little on reason. He left school at the age of 15, when his boyish fancy was one day attracted by the coloured jars in a chemist's window and he determined to become a chemist. Accordingly he was apprenticed. When, however, he came to work he was as much disillusioned with the duties and with the gorgeous coloured jars as was the well-known Rosamond of Miss Edgeworth, and at the end of his apprenticeship he entered Edinburgh University as medical student. Soon after qualifying he became assistant in the firm of two medical men in Burnley, Dr. William Briggs and Dr. John Brown. This was in 1879, and in the course of his practice he met with the case which was to determine his life's work. It was that of a young woman who died from heart failure during labour, and Mackenzie asked himself whether, if he had had a wider knowledge of heart affections, he could have foreseen and possibly averted the tragedy. So he took hundreds of tracings with a Dudgeon sphygmograph, and also others of the venous pulse in the neck with a filament of straw stuck to the vein writing on smoked paper, which crude device was followed in time by an ingenious polygraph devised by himself. Years of study convinced him that every murmur of the heart was not necessarily a sign of disease, but that a heart in which a murmur was present could do its work perfectly well so long as it was not over-driven. The outcome of all these researches was, as every medical man knows, the discovery of the conditions known as auricular fibrillation and heart-block.

Of the coming of the Burnley practitioner to London, of his welcome by the College of Physicians and the Royal Society, of his success and honours, an account must be sought in Dr. Wilson's pages. Here also will be found the reasons for Mackenzie's dramatic resolve, when at the height of his fame, to give up London and go to St. Andrews, there to devote the rest of his life to clinical research on the early symptoms of disease. The building in which the research was carried on was called the St. Andrews Institute of Clinical Research, now known as the James Mackenzie Institute, and remains alike as a memorial to his name and as a seat for the investigations which the broad philosophy of his outlook made him feel to be imperative. Despite all the stress laid upon family and personal history, both in institutional teaching and in private note-books, since clinical medicine began to be systematised some hundred years or more ago, the fact remains that the beginnings of disease processes did not receive until recently proportional attention. In Mackenzie's conception of an Institute devoted to clinical investigation we see a formulation of the fundamental truth on which he insisted that medicine is a special branch of science dealing with a special group of phenomena, where the clinical investigator must apply the methods which are specially suitable for his purposes. It was essential to this conception that the knowledge derived, mainly from general practice, by the watching of ill-health over a long course of years should be categorised and tested, and along the lines thus suggested

the work at St. Andrews is now proceeding. It is one of the ironies of fate that soon after he went to St. Andrews Mackenzie knew for a fact that he was stricken with angina pectoris, and from this disease he died on Jan. 25th, 1925.

A book which will interest not the medical man alone, but also any intelligent layman. It is clearly and often eloquently written, and good reasons are given for the striking title.

LA GRIPPE.

By Dr. PIERRE LEREBOULLET, Professeur agrégé à la Faculté de Médecine de Paris, Médecin de l'Hôpital des Enfants Malades. Paris: Baillière et Fils. 1926. Pp. 144. Fr.8.

MOST of the books dealing with influenza are either treatises on Pfeiffer's bacillus or discussions of that medley of infections to which the layman has given this name. Dr. Lereboullet's modest little volume is a refreshing clinical and pathological study. Pandemic influenza attacks the world with such extreme violence and at such rare intervals that a new generation of medical practitioners is overwhelmed at a time when their experienced predecessors are unable to help them. Between pandemics it is next to impossible to obtain first-hand knowledge, and therefore we heartily commend to medical students this excellent account of a dreadful disease.

EPILEPSY.

A Functional Mental Illness. By R. G. ROWS, M.D. Lond., Pathologist and Medical Officer, County Mental Hospital, Prestwich, Manchester; and W. E. BOND, M.R.C.S. Eng., L.R.C.P. Lond., a senior medical officer to the Ministry of Pensions. London: H. K. Lewis. 1926. Pp. 138. 8*s*.

THAT older views on the nature of epilepsy have been to some extent modified by war experiences is doubtless now a truism; it can scarcely be questioned, at any rate, that types of epileptic phenomena then occurred with no little frequency which were much less often encountered in ordinary civilian practice. Yet it would be erroneous to suggest that fits in which a psychogenic factor was conspicuous had up to the time of the war been unknown; on the contrary, the variety was fully recognised, if somewhat neglected. In a large proportion of war cases of epilepsy so obvious seemed the underlying psychological mechanism that it was only natural that attempts should be made to unify all epileptic phenomena on that basis and to find in each and every manifestation of the condition the action of a mental agent. The late Dr. R. G. Rows has left on record his conclusions, based on abundant war material, and his formulations are given in the book without anything having been altered by his collaborator.

Briefly, it is Dr. Rows's aim to demonstrate that epilepsy is one and indivisible, and that behind its simplest no less than its most complex exteriorisation lies the action of a mental factor. This factor is a disturbance of consciousness associated with an emotional state; "in every instance" this emotional state can be detected, and the phenomena of the fit are a reaction to express the emotion. This contention is declared to be substantiated by a consideration of the "meaning" of the movements in convulsions, and an attempt is made to support the argument on physiological grounds—viz., that the vasomotor-sympathetic system is implicated in fits and that its relation to the emotional sphere is acknowledged. Holding these views the authors treat their cases by "explanation, exploration, and re-education," and categorically state that drugs "have no legitimate place in the treatment of this or any other form of mental illness," unless as a temporary measure.

While there is something to be said for the hypothesis that disorders at the mental level are often enough responsible for somatic symptoms, the universal application of it to the phenomena usually called epileptic, whatever their clinical type, raises more difficulties than it settles. The authors slur over the obvious hindrance to acceptance that resides in the commonplace variety of infantile convulsions by saying that "attention must be given to the little control over the emotions possessed by the child"; what of the new-born infant, whose cortex may discharge for hours after injury in parturition? What of Jacksonian epilepsy, which may for years be limited to one particular muscular group, as in epilepsia partialis continua? We are convinced of the applicability of the authors' conclusions to certain cases called epileptic; we are equally unable to find in them a plausible explanation of other types of the syndrome that come under the clinician's notice daily.

DIAGNOSIS.

A Manual of Normal Physical Signs. By WYNDHAM B. BLANTON, B.A., M.A., M.D., Associate in Medicine, Medical College of Virginia. London: Henry Kimpton. 1926. Pp. 215. 12*s*.

THERE is something to be said for a brief compilation of the normal results of physical examination of healthy individuals such as is presented in this book. At the same time it must not be forgotten that the step from the normal to the abnormal is an easy one, the normal percussion note in one region of the chest, for example, being abnormal when obtained elsewhere, and therefore the complete divorce of the normal from the abnormal is neither possible nor likely to be satisfactory. Dr. Blanton's idea in preparing his book, however, was to help the beginner, and for this purpose he introduces a chapter on sound and endeavours to deal with the subjects of percussion and auscultation on a physical basis. This attempt has not been very successful, and there are certain errors in his book which render its value for beginners very doubtful. The right apex is described as a normally dull thoracic area (p. 57), and inspiration in this same situation is said to be less intense as compared with the left (p. 74). The account of bronchial breathing is poor, no reference being made to the pause occurring between inspiration and expiration. Râles are classified as moist and dry, no mention being made of rhonchi (p. 79). When the circulatory system comes to be considered the third heart sound is given as prominent a position as the more usual first and second sounds (p. 116), and this is bound to confuse the young student; nor is the description of the method of obtaining the diastolic pressure lucid.

PEDIATRICS.

Diagnosis of Children's Diseases. Third (German) edition. By Prof. E. FEER, Zurich. Translated by C. A. SCHERER, M.D. London: J. B. Lippincott. 1925. Pp. 551. 35*s*.

THE third edition of Prof. Feer's work, which has achieved notable success on the continent, has now been brought within reach of the English reader by the enterprise of Dr. Scherer. The book is intended to be a guide to diagnosis, and is not concerned with systematic description or with treatment of diseases; symptoms are described and the differential diagnosis of their possible causes is discussed in detail. Prof. Feer deprecates the tendency to allow laboratory tests to supersede, instead of to follow, thorough clinical examination of the patient, and the reader will be impressed throughout the book with the paramount importance of detailed clinical observation in this branch of medicine. The illustrations are numerous and include colour-plates of the exanthemata. As a supplement to the systematic text-books this work should be of great value to students and practitioners.

Dystrophien und Durchfallskrankheiten im Säuglingsalter. By Prof. LEO LANGSTEIN. Leipzig: Georg Thieme. 1926. Pp. 207. M.14.

THE principle underlying this work is that both the dystrophies and diarrhœas of infancy can be

successfully treated by simple methods provided that an accurate estimate of the clinical and ætiological factors is obtained. The book consists of two parts, dealing respectively with dystrophies and diarrhœas. The classification and differential diagnosis of different types are presented in a concise and lucid way and accompanied by accounts of individual cases. Many of these are illustrated by photographs and charts of feeding and weight. The method of treatment which the author advocates has the great advantage of being extremely simple, consisting almost entirely in the use of human milk, buttermilk, and diluted cow's milk with added carbohydrate. It has also the practical disadvantage that a large measure of its success seems to depend upon the use of expressed human milk, which is not accessible to those who work under less ideal conditions. Much emphasis is laid on the dangers of dehydration and the importance of combating it; curiously little is said about the use of intraperitoneal infusions in accomplishing this end. Careful attention to quantitative requirements and avoidance of overfeeding occupy a prominent place in the author's régime. Prof. Langstein is impressed with the extent to which practitioners are deterred from scientific treatment of these disorders by the constantly changing stream of complicated methods which the literature of the subject presents. His book was written with the object of bringing the practitioner into touch with the methods of diagnosis and treatment of infantile malnutrition which are evolved from the experience of pediatrists working in special institutions, and it may be recommended as a successful attempt to simplify a complicated subject.

DIETETICS.

What's Best to Eat? By S. HENNING BELFRAGE, M.D. Lond., M.R.C.S., L.R.C.P. With a Practical Supplement by LUCY H. YATES, M.C.A. London: William Heinemann (Medical Books), Ltd. 1926. Pp. 199. 7*s.* 6*d.*

The Importance of Diet in Relation to Health. The People's League of Health Lectures. London: George Routledge and Sons, Ltd. 1926. Pp. 130. 3*s.* 6*d.*

Food. Its Composition and Preparation. Second edition, revised. By MARY T. DOWD and JEAN D. JAMESON, Teachers of Household Science, Washington Irving School, New York. London: Chapman and Hall, Ltd. 1925. Pp. 177. 7*s.* 6*d.*

Dr. Belfrage is an ardent disciple of the "intestinal stasis" school, and his new book on dietetics therefore owes a great deal to the teaching of Sir William Arbuthnot Lane. He sets out in some detail the principles of diet, attaching great importance to the mineral salts and the vitamins contained in food. It is not easy to follow exactly how the terrible poisons alleged to be generated in intestinal stasis get into the blood stream, as it is stated they do (p. 77), for in the first place the passage of absorbed foodstuffs to the liver is described (p. 72), and secondly the detoxicating action of this organ in the case of ptomaine is carefully emphasised (p. 83). The intelligent reader may well ask what is happening to the liver when the poisons produced in intestinal stasis arrive. The answer that the liver cells get overworked and break down is a mere speculation with little or no experimental proof. Naturally the list given of diseases caused or predisposed to by intestinal stasis is a long one, and the author also appears to believe that relative deficiencies in the vitamins of food "are very common and lead eventually to very serious damage" (p. 26), a view which is not held by most dietitians. Another point calling for criticism is the sweeping recommendation of "roughage" for children "from their earliest years" (p. 75), since it has been shown, for example, by G. F. Still, that brown bread, coarse oatmeal, and the like, are frequent causes of "indigestion" and abdominal pain in children. The practical supplement of recipes and cooking is good, and it is a pity that the value of the rest of the book is impaired by too one-sided an attitude to health and disease.

The lectures delivered in 1925, under the auspices of the People's League of Health, have been published in book form. Of these lectures that by Sir D'Arcy Power on the history and geography of mankind's feeding habits is the most interesting, because it contains almost the only new material which distinguishes this book from many others published during the last few months. Hippocrates is reputed to have said that all diseases commence in the stomach, and Sir D'Arcy Power's lecture goes to show that as civilisation has advanced this dictum has become more strikingly true, although there are signs at the present day of a reaction against our somewhat gross habits of eating and drinking. The other lectures in this volume, on the general principles of diet by Dr. Leonard Hill, on vitamins by Prof. W. D. Halliburton, on infant feeding by Dr. H. Scurfield, on feeding and breeding of cattle by Dr. M. J. Rowlands, and on food preservatives by Prof. W. E. Dixon, are consistent in their high standard of intelligent and balanced argument.

The American school text-book is also characterised by its well-arranged and well-balanced material. The authors approach the subject in a scientific manner, classifying, explaining, and describing food in its raw and cooked state and dealing fully with the intermediate process. Its illustrations are excellent, but it suffers from the usual disadvantage of American books on diet in this country that many of the foodstuffs are not known; even a glossary fails to get over the difficulty of the American colloquial terms. Modern advances in dietetics are, however, well described.

JOURNALS.

JOURNAL OF INDUSTRIAL HYGIENE. October, 1926. —Disease and the Workmen's Compensation Act is dealt with in the opening paper by Sir K. W. Goadby, a specialist medical referee. After describing the procedure of the Act, he points out that compensation in 1924 cost industry double what it did in 1911. The cost per person in the mining industry in 1924 was 56*s.* 2*d.* as compared with 8*s.* 7*d.* for factory operatives. Coal-miners accounted for over 90 per cent. of all claims; the claims for one disease alone, nystagmus, peculiar to them, being equal to all other claims for occupational diseases taken together. Claims for dermatitis increased from 270 cases in 1919 to 709 in 1924. Incapacity for compensated disease is shown to be much greater than for compensated accidents.—Three articles follow by E. L. Middleton, dealing with three matters concerned with the cotton industry. The first is weavers' cough, a trouble which breaks out in epidemic form from time to time in certain mills, and appears to be associated with the occurrence of mildew upon the cotton threads. The disease is carefully described and case-histories are given. The exact mould which causes trouble has not been isolated, nor have means yet been devised for abolishing moulds from weaving sheds. The second subject is that of dust in cotton-card rooms. This dust is known to cause a characteristic form of spasmodic asthma after years of exposure. Details are given of samples of dust collected under varying circumstances. The constituent of the dust at fault has not yet been determined. Further investigation is required. Meanwhile all dust generated in the early processes of opening and carding cotton should be carefully prevented from gaining access to the workrooms. The third article deals with the presence of mineral oils in the atmosphere of cotton-spinning rooms. The occurrence of mule-spinners' cancer, which is ascribed to oil on the spinners' clothes, adds interest to this investigation. Samples of air were taken in various positions in spinning-rooms and fine droplets of oil were found to be present. Herein may be a possible explanation of the access of oil to parts of the skin not exposed to oily surfaces, such as machinery, nor in contact with saturated clothing.

THE PANEL CONFERENCE.

DISCIPLINARY POWERS OF MINISTRY OF HEALTH.

THE annual Conference of representatives of local medical and panel committees was held on Oct. 21st in the Great Hall of the British Medical Association, under the presidency of Dr. E. K. LE FLEMING (Dorset). The Conference considered the report of the Insurance Acts Committee (I.A.C.), and devoted much time to discussing the right of panel practitioners to appeal from decisions by the Minister of Health.

Dr. H. G. DAIN (Birmingham), Chairman of the I.A.C., introducing the report of the Committee, said that since the last conference the Royal Commission on National Health Insurance had made its report, and the Government had founded part of their Economy Bill upon its findings. It was satisfactory that medical benefit was recognised as being a first charge, but as there were increasing demands for sickness benefit it was uncertain whether there would be enough money to meet the ordinary claims without encroaching on the funds available for additional benefit. There was reason to suppose that practitioners were not being as careful as formerly in issuing certificates of sickness, and the situation was causing much anxiety to the Ministry of Health. The Committee had, therefore, asked Sir Walter Kinnear, of the Minister's staff, to lay his views before the Conference.

DISCIPLINARY PROCEDURE.

After a motion had been carried asking the I.A.C. to reconsider the representation of Wales and other areas on the Committee, with a view to adding not more than two members to the executive, the Conference proceeded to discuss a communication received on Oct. 9th from the Ministry of Health. This was a reply to a letter sent on July 5th by the I.A.C., in which the Committee expressed its dissatisfaction with the negative attitude of the Minister on the general question of disciplinary procedure and made suggestions for reform. The reply now received describes the Committee's letter (1) as a claim that the Minister shall have no jurisdiction in questions relating to the treatment rendered by the practitioner to his patients, and (2) as a suggestion that, failing his acceptance of this claim, the Minister should consider under what conditions his jurisdiction could be limited by some right of appeal to the courts. To the first proposition the Minister answers that he cannot forgo the responsibility of considering whether reasonable skill and care have been exercised by panel practitioners. He recognises, however, that on medical issues he must necessarily be guided by professional advice, and suggests that some system might be devised by which the I.A.C. should nominate a small panel of practitioners whose advice would be sought in particular cases. If this suggestion be accepted, he proposes that the I.A.C. should consider at what times and in what circumstances such advice should be sought. The alternative proposal, to allow an appeal to the courts, does not meet with the Minister's approval. Such an appeal, he considers, would be inconsistent with constitutional practice, since, as the Royal Commission pointed out (paragraph 444), the proposal "involves placing upon the courts of law the responsibility for deciding questions of a kind which can be more appropriately decided by a Minister who is answerable to Parliament for the manner in which he exercises his discretion." The letter contains the statement that, "with every desire to give the profession all reasonable safeguards, the Minister is unable to accept any of the proposals which have been put forward on these lines."

This reply from the Ministry having been received by the Conference, Dr. DAIN said that the proposed insertion of a professional tribunal somewhere in the machinery would undoubtedly be a step towards improvement. The Conference accepted his suggestion that the offer should be referred for consideration to the I.A.C., who should discuss its terms with the Minister and report to the Conference at a later date.

Dr. H. B. BRACKENBURY (Middlesex) pointed out that it might well be worth while to hold a special session to consider so important a proposal.

The Right of Appeal to the Courts.

After approving a motion by Kent that "the Royal Commission should have called for such further evidence as it required to substantiate or refute professional assertions in connexion with the abuses of the disciplinary machinery, such evidence having been specifically offered it," the Conference proceeded to consider a motion by Cheshire as follows:—

"That there should be an appeal to the High Court from decisions of the Minister, not only on grounds of procedure, but on the merits of the case."

Dr. L. J. PICTON, the proposer, remarked that this same motion had been laid before every conference for many years. At first it had aroused little interest, but as time went on there had been a series of cases in which decisions seemed to have been made without common sense or common justice, and the movement to demand an appeal had gained ground. Last year, indeed, the motion would doubtless have been carried but for opposition based on the ground that the whole position was under review by the Royal Commission. Dr. Picton described a recent case in which a patient brought an action for damages before the civil courts whilst the charges against the practitioner were still before the Ministry. Although a decision was overdue, the Minister had refused to give it whilst the civil action was sub judice. From this it was clear, said Dr. Picton, that the right of practitioners to appeal to the courts would be a salutary check on the working of the Ministerial machinery, and it was only just, moreover, that doctors should have the same right of appeal as their patients. It was absurd to say that this would open new floodgates of litigation, for the gates were already open to insured persons. It was the right of every citizen to appeal to the courts of the land, and it was no argument to say that medical matters were too technical for lay judgment, since many other equally technical subjects were dealt with by laymen. As Mr. Forster had pointed out in 1911 in the House of Commons, the loss of a doctor's livelihood was too serious a matter to be left in the hands of Government officials.

Dr. GORDON WARD (Kent) said that the Minister's attempt to discredit appeals to the courts showed that he was afraid of them. As a writer in THE LANCET had pointed out in 1923, nurses, midwives, and dentists had the right of appeal to the High Court; it was nonsense to say that a medical appeal would be unconstitutional.

A representative speaking both as barrister and panel practitioner, did not agree that the floodgates of litigation were already open. In the case quoted by Dr. Picton, he said, the patient had not appealed against a decision of the Ministry, but had merely taken action in law. His own experience of courts of inquiry was that nothing could be fairer, and that every effort was made to find extenuating circumstances for the medical man.

Dr. A. FOSTER (Worcester) opposed the motion because appeal to the courts was unconstitutional, and would mean long delay and expense. It was contrary, he said, to legal precedent to make an appeal from a Government Department to the High Courts, and doctors would not be the gainers if they had the additional worry of defending these actions. The Ministry, however, had tried to do what the courts had never attempted—it had tried to define "reasonable care." In this it had failed.

Dr. H. ROSE (Bucks) said that in his experience the Ministry was most fair in its treatment of doctors.

Dr. H. S. BEADLES (Essex) complained that the Ministry did not always take the advice of the courts

of inquiry; this was the reason why an appeal from the Minister's decision was necessary.

Dr. J. HOLMES (Bury) advocated support for the Insurance Acts Committee in demanding an appeal.

Dr. C. J. PALMER (Notts) hoped that there would be no appeal to the courts, since an appeal must involve undue publicity for the doctor and unnecessary expense. He gave illustrations of the inability of lay courts to understand medical matters.

Dr. G. C. GARRATT (West Sussex) said that the courts of inquiry were certainly judicial, and he saw no reason for a right to appeal against their decisions. In one case, however, in which a court of inquiry had found for a doctor and granted him costs, the Ministry had overthrown the court's decision and fined the doctor £20. Dr. Garratt gave three instances in which, he said, the Ministry's decision had been anything but fair, and had been contrary to the local recommendation. It was regrettable that the Ministry did not pay attention to the particular local conditions under which practitioners worked. It had never been the intention of Parliament, he maintained, that the present powers of the Minister of Health should be invested in one man; they had been given to a body, now swept away, on which panel practitioners were represented. It had been suggested that the right of appeal would involve much waste of time and money. This was quite true. But surely this would be a safeguard against common resort to appeals. There was already an appeal from the Minister's decisions on the ground of their illegality; why should there not be an appeal on grounds of injustice?

Dr. BRACKENBURY said that the Conference was discussing a specific remedy for the abuses of the present system. That remedy, it was suggested, should be a universal right to appeal. If the Conference were to pass a motion calling for such a right it would be tying the hands of the Insurance Acts Committee, which would have to demand a right of appeal in every case. Everyone would agree that there should be such a right in certain defined types of cases, but if a general right existed it would not be the monopoly of practitioners. Patients and approved societies would receive equal privileges, and he did not want to see them appealing to the courts in cases where the Ministry's decision had been given in favour of the doctor.

Dr. DAIN said that all the profession wanted was machinery that would provide for perfect justice. If such machinery could be devised in any other way, no one would want to go to the High Courts simply for the sport of it. He believed it not impossible to secure such internal arrangements as would be satisfactory.

Dr. D. F. TODD (Sunderland) complained that the demand for an appeal was put off year after year; it was now time that something should be done. Why should not the Minister be made to carry out the decisions of courts of inquiry? What was the use of holding such courts if he could override their decisions?

Dr. BRACKENBURY, seconded by Dr. PETER MACDONALD (York), then proposed, as an amendment to the motion:

> That in the opinion of this Conference there should be an appeal to the courts on grounds of (1) illegal, irregular procedure; (2) alleged vindictive penalties; and (3) where common law action by the patient would normally lie; and that the question of appeals in other cases be referred to the Insurance Acts Committee for consultation with the Ministry.

Dr. PICTON, opposing this amendment, said that his original motion was a useful expression of opinion. The Conference should tell the Insurance Acts Committee what it really thought. The amendment was, however, carried by 90 votes to 30 and was then carried as the substantive motion.

On behalf of the I.A.C. Dr. DAIN then proposed:—

> That this Conference regards as serious the situation which arises in consequence of the negative replies of the Ministry of Health in connexion with the methods and machinery for dealing with complaints against insurance practitioners; and pledges itself to support proposals (*a*) to secure equal justice for practitioners as for insured persons and approved societies; (*b*) to secure improved methods for dealing with complaints of minor importance; and (*c*) to organise a most strenuous resistance to any claims of the Ministry of Health or of Insurance Committees to judge as to the propriety of the treatment adopted by a practitioner in attending his patient or the relative degree of care and skill shown by a practitioner in such attendance as compared with that of other registered medical practitioners.

Discussion arose only on part (*c*) of this motion. Dr. GORDON WARD opposed it because, he said, no Government Department could possibly bind itself to take no interest in a particular sphere of the work for which it was responsible. The Ministry, moreover, had already turned down the proposal.

Dr. J. S. MANSON (Warrington) hoped that the motion would be referred back to the I.A.C. The organisation of strenuous resistance to the Ministry's claim to discipline careless practitioners might make the public say that the British Medical Association was trying to shield incompetence.

Dr. H. J. CARDALE (London) wanted the words "care and" deleted from the motion, whilst Dr. BRACKENBURY hoped that it would be passed exactly as it stood, since in this form it had been approved by the representative meeting of the B.M.A., and it would be a pity to make verbal changes where there was no fundamental difference of opinion. Nothing short of a drastic letter, he said, would draw a reply from the Ministry.

Dr. DAIN said that it was necessary to be quite definite on this question. When a practitioner undertook an insurance contract he undertook, as a matter of course, to give his patients the benefit of "ordinary skill"; he did not for a moment suppose that his actions would come up for judgment by the Minister or his officers who would make decisions about them on the strength of a written report. It was intolerable, Dr. Dain thought, that the Minister should be able to pick out some part of the story—perhaps a part not much discussed by the Court of Inquiry—and found his own judgment upon it.

The motion was carried by a large majority.

Evidence of Character and Previous Conduct.

On a motion by the I.A.C., recommending the Conference to accept the proposals of the Ministry as to the hearing of evidence of character and previous conduct, Dr. DAIN said that these proposals were in keeping with ordinary legal procedure. Courts of inquiry sat to hear a particular charge brought against a doctor. The presiding barristers ruled that it was impossible to receive evidence not directly bearing on the case and therefore refused to hear evidence of character from the doctor's friends. Similarly they would not take evidence against the doctor submitted by the patient or approved society. The I.A.C. agreed, however, that after a decision on the facts had been reached it was proper for the judge to hear evidence of character and previous behaviour before he passed sentence.

Dr. GORDON WARD said that in an inquiry *all* the evidence should be heard. Everything must be above board. Inquiry committees should be allowed to report on the inference of the facts—that is, whether the doctor was guilty or not. To this Dr. DAIN replied that it was not relevant to hear evidence of character in deciding on the truth of a specific charge. It would be a mistake not to adhere to the legal precedent.

The Conference, by a very large majority, agreed to accept the Ministry's proposals.

Increased Claims for Sickness Benefit.

Sir WALTER KINNEAR (Ministry of Health) then addressed the Conference on the increase of claims for sickness benefit and the financial position of the approved societies. He asked that no report of his statements should be published. The Conference warmly thanked Sir Walter Kinnear for his clear statement of the facts, and at the afternoon session passed a resolution asking the I.A.C. to consider

what practical steps could be taken to meet the difficulties which he had raised, and requesting representatives of local medical and panel committees to use their influence along the lines he had suggested.

Dr. M. W. RENTON (Kent) proposed a motion welcoming the finding of the Minority Report of the Royal Commission that "the approved society system is a hindrance to the development of a complete public health policy," but the Conference decided to pass on to the next business, as the time was held inappropriate for discussing the many issues which the motion might raise.

Maternity Benefit.

The following resolution, also by Kent, was then discussed :—

That this Conference welcomes the finding of the Royal Commission that "the service element (of maternity benefit) should be administered by the local health authorities and be coördinated with the other local medical services," understanding that this implies that maternity services will not be within the scope of the contract of medical service under the Insurance Acts.

Dr. BRACKENBURY, opposing, said that he trusted that the time would never come when maternity work would be taken out of the sphere of the family or insurance practitioner.

Dr. E. A. GREGG said that the Conference would be very unwise to give an impression that it thought that maternity work should be put into the hands of local health authorities. It should be remembered that the panel doctor was only an insurance practitioner in one aspect of his work.

Dr. GORDON WARD said that, no matter what the Conference did or said, the machinery provided by local authorities for carrying on maternity work was bound to expand and increase. He would, of course, oppose any suggestion that the midwifery of an area should be the monopoly of a single specialist, but he thought that panel practitioners would do well to make use of the local authorities' services rather than the cumbersome machinery of the Insurance Acts.

The motion was lost.

Keeping of Records.

On a motion by the I.A.C. to approve the proposed machinery for dealing with cases of alleged failure to keep proper medical records, Dr. DAIN said that the Committee had not objected to the Minister fining practitioners where the facts were not in dispute, but it did object to medical records going before any committees on which laymen sat, such as the medical service subcommittees. The Minister had been in the habit of sending down a medical officer to investigate complaints, and it had now been arranged that two doctors, representing the local panel committee and a neighbouring panel committee, should sit with this officer and be empowered to send to the Minister their comments on the case.

Dr. GORDON WARD pointed out that a fine of £50 was sometimes inflicted in these cases. They were too important for hole-and-corner methods. Why should not a barrister sit on the Inquiry Committee? To this Dr. DAIN replied that courts of inquiry were only used when a claim was made that a practitioner should be taken off the panel. The new proposals were the first suggestion that anyone besides the medical officer from the Ministry should hear these cases.

The Conference, by approving the I.A.C.'s motion, accepted the new proposals. The two following motions, proposed respectively by the I.A.C. and Hastings, were also carried :—

That the Conference reiterates the opinion previously expressed on the subject of medical records—namely, that the value of careful clinical notes and essential dates on medical records is fully appreciated, but that it is unnecessary to record all attendances, &c. (except where practitioners have agreed to keep full records of work done for statistical purposes). The Conference desires to point out to the Minister of Health that the experience gained of the working of the recommendation of the Inter-Departmental Committee on Medical Records of 1920, on which the present record is based, has caused some of the medical members of that Committee to alter their views on this subject.

That this Conference draws the attention of practitioners to the inconvenience caused by neglect to forward record cards of persons transferred from one practitioner to another, and requests that they shall be sent on as soon as possible after the removal from the list.

Production of Medical Cards by Patients.

An interesting discussion arose on a motion by the I.A.C. to approve the principle that a practitioner is not entitled to demand the production of a medical card, or, alternatively, the payment of a fee, as a condition of providing treatment for an insured person already on his list, unless he has reasonable grounds for doubting the patient's identity. Among those who spoke on this motion was Dr. CARDALE, who held that it would be very unwise to sap the rule that a practitioner was always entitled to demand a card. Certainly it was not necessary to take the fee where a card could not be produced, but the claim for a fee was a valuable lever. If this lever were given away patients would bring their cards or not, just as they liked.

The I.A.C.'s motion was, however, passed.

On a proposal by Hastings that the I.A.C. should press for the abolition of Clause 7 (para. 3) in the Terms of Service, Dr. A. E. LARKING wittily described the difficulties of panel practitioners at health resorts. To Hastings, he said, came large numbers of highly-dressed ladies and gentlemen. When they came to see a doctor he naturally did not like to ask if they were panel patients, and often attended and prescribed for them for some time in blissful ignorance of their true status. It was most unfair of these people to come and pose as private patients, thinking—though most unjustly, of course—that they would get better treatment. The medical practitioners of Hastings thought it only right that their patients, if insured, should disclose the fact.

Dr. A. W. HOLTHUSEN (Southend) supported Dr. Larking's plea by telling a story in which a woman and her friends had deliberately masqueraded as private patients and then had asked for a refund of fees which they had paid.

Dr. BRACKENBURY opposed the motion on the ground that the clause complained of had been put in so that such cases—often cases of bona fide mistakes by doctors—should not always have to go before medical service subcommittees.

The motion by Hastings was not agreed to.

Complaints against Officials of Approved Societies.

Dr. W. COOK (Warwickshire) described how he had been forced (out of charity) to visit a patient a mile away in order to give her a certificate of sickness, because she had been told by the agent of her approved society that if she stirred a foot outside her own district she would forfeit her sick pay.

The Conference passed the following resolution :—

That the Insurance Acts Committee be instructed to press for power being given to the Medical Service Subcommittee or other approved body to investigate complaints made by insured persons, insurance practitioners, or panel committees against approved society officials who alter or in any way falsify medical certificates, or otherwise interfere with practitioners in the performance of their duties.

Remuneration.

A motion by the I.A.C. "that the question of the amount of the capitation fee for 1927 for the treatment of insured persons be not raised on behalf of insurance practitioners" was approved by the Conference. In proposing an amendment by Kent, that any decision as to stabilisation or revision of the capitation fee should be preceded by an inquiry by the profession into the market value of the panel practitioner's services, Dr. GORDON WARD said that the present remuneration was based on the original fee which had merely been modified according to the cost of living and other factors. The capitation fee for panel patients ought, however, to be calculated from the cost of similar services to private patients of the same class. In Kent this would justify a capitation fee of 12*s.* or 13*s.*

Dr. BRACKENBURY did not agree that the present capitation fee was based on the original figure. It was quite unnecessary, he thought, to hold an investigation into the "market value" of the doctor's services—a term whose use he deprecated—since whenever the proper value of the capitation fee was being calculated the fees charged to private patients must inevitably be taken into consideration.

Dr. J. W. BONE (Luton) thought that it was impossible to stabilise the capitation fee. An estimate from charges in Kent might show that the fee should be higher than it was, but in poorer counties the result would be otherwise. Dr. Bone personally was content that his remuneration should be at the present capitation rate and feared that revision might make it lower rather than higher, for this was an unsuitable time to suggest a change.

The amendment by Kent was lost.

Dental and Ophthalmic Benefit.

Dr. F. W. COAKER (Worcestershire) proposed a motion urging the I.A.C. (1) to approach the Ministry with a view to steps being taken towards making dental and ophthalmic treatment statutory benefits, and (2) to make arrangements with the Ministry so as to make it permissible for any insurance practitioner to state on the written recommendation for specialist treatment the name of the specialist he advised his patient to consult.

Dr. C. M. STEVENSON (Cambridgeshire) complained that some of the approved societies were sending all their patients to one ophthalmic specialist, and sometimes refusing to pay the fees of specialists whom the patient himself had chosen. He could not, however, support the second part of the motion because he thought that the choice of an ophthalmic surgeon should rest with the insured person; the panel doctor had done enough when he had given a verbal recommendation.

Dr. H. W. POOLER (Derbyshire) said that the trouble was that approved societies were recommending opticians instead of ophthalmic surgeons. One society had written from Manchester to a patient of his, saying that their own optician did not go so far as the patient's neighbourhood, and that they would be glad if he would call on any local optician who could prescribe glasses.

After some further discussion Dr. DAIN pointed out that dental and ophthalmic benefits were surplus benefits; the societies had a perfect right to arrange for themselves how they should spend the money, and the Ministry had no power to dictate to them. It would therefore be futile to pass the Worcestershire motion. Apart from this, if every panel doctor was to make a practice of sending to ophthalmic surgeons all patients who required examination of the eyes the money available for ophthalmic benefit during the next five years would all be spent in 12 months. The increase of ordinary sickness claims made it probable in any case that there would soon be no funds left for ophthalmic benefit, and the problem was thus likely to solve itself shortly. He saw no objection to practitioners putting down the name of a specialist on their recommendations.

Dr. Coaker's motion was lost.

Speaking on a further motion by Hastings, approving the principle that wherever the practitioner considered further advice necessary the patient should in the first place be referred to an ophthalmic surgeon and not an optician, Dr. LARKING pointed out that the panel doctor's certificate might take various forms. He might recommend a visit to an optician for glasses or to a surgeon for further investigation. To send all cases to a specialist, he thought, would defeat its own ends. Societies should not have had placed on them the duty to decide. It was sometimes suggested that the practitioner should give some idea on the certificate of what was wrong with the patient, so as to aid them in their decision; but to do this would be to give away the right to send all patients to the ophthalmic surgeon.

Dr. G. A. RORIE proposed an amendment by Dundee suggesting that cases in which the practitioner was satisfied that only spectacle-fitting was required should be excepted from the B.M.A.'s recommendation. This amendment was lost by 47 votes to 52.

Dr. ALFRED COX (B.M.A.) said that he wished that it could be realised how muddled the position was becoming. They would soon have to make up their mind whether general practitioners should discriminate between those cases which required diagnosis and treatment by an ophthalmic specialist and those which did not, or whether all cases in which the eyes required consideration must be sent to a specialist at once. As Dr. Dain had pointed out, there might soon be no benefit left.

The Conference then accepted a proposal by Dr. DAIN to proceed to the next business.

Further Proceedings.

On a motion by Kent asking the I.A.C. to secure statistics on certain special services included in the capitation fee payment, Dr. G. C. ANDERSON gave an account of the B.M.A.'s work in collecting figures from panel and non-panel practitioners.

Dr. J. P. WILLIAMS-FREEMAN (Andover) and Dr. H. R. BROWN (Essex) contributed to a discussion, on the cost of prescribing, which led to a motion being passed accepting the Ministry's offer to increase the 2*s.* capitation grant to 2*s.* 3*d.* as the best at present obtainable.

Several proposals dealing with the method by which an insured person changes his doctor were referred back to the I.A.C., and a resolution was passed "that insurance practitioners should not be expected to provide sickness certificates, prescriptions, or medicine for tuberculous patients who are in regular attendance and in receipt of treatment at the tuberculosis dispensary."

Dr. J. MCCREA (Berkshire) proposed:—

That in the opinion of this Conference, approved society officials should not have the power to refuse sickness benefit on medical grounds alone, to any insured person, who has been certified as incapable of work by a doctor on the panel, unless he/she has been reported fit for work by the regional medical officer; and that the Insurance Acts Committee be instructed to take immediate action to enforce this reform.

This motion was passed in spite of a protest by Dr. DAIN, who said that it was quite impossible to compel the societies to accept a doctor's certificate, though patients could appeal if the certificate was refused. The I.A.C. would find itself unable to act in the matter.

Dr. R. FORBES (Gateshead) raised the question of the appointment of medical referees by approved societies.

Dr. BONE proposed that the I.A.C. should undertake an investigation of drugs for the new British Pharmacopœia from the point of view of insurance practice, and this suggestion was endorsed by the Conference.

Amongst other motions proposed and carried at the Conference were the following:—

That there be no relaxation of effort in the matter of obtaining contributions for the National Insurance Defence Trust until that Trust has reached the total of £250,000.

That the Conference approves of the proposal that Insurance Committees should notify parties in cases heard before the Service Subcommittee of their right of appeal and of the power of the Minister to award costs as he may think fit.

That the Conference agrees to the proposal that the notice issued to insured persons on the list of a deceased or retiring practitioner, informing them of their right to a fresh choice, shall intimate that they would be deemed to have consented to their names being transferred to the successor's list unless within one month of receiving such notice they gave notice of objection to such transference.

That this Conference is of opinion that the existing arrangement whereby that portion of insured seamen who, as members of the Seamen's National Insurance Society, obtain their medical benefit through the society, should be discontinued, and that all insured seamen should obtain their medical benefit in the ordinary manner through Insurance Committees.

Dr. E. K. LE FLEMING was unanimously re-elected Chairman of the Conference for the ensuing year, and the proceedings ended at about 6.30 P.M.

THE LANCET.

LONDON: SATURDAY, OCTOBER 30, 1926.

THE RIGHT OF APPEAL.

YEAR after year the panel doctors have been demanding the right to appeal (preferably to the law-courts) from the disciplinary decisions promulgated by the Ministry of Health under the National Health Insurance Medical Benefit Regulations. Their persistence has had a twofold origin. In the first place they have been conscious of specific grievances—ministerial decisions seemingly at variance with the findings of local inquiries, a somewhat arbitrary infliction of lesser penalties when the full penalty of removal from the medical list has not been imposed, the withholding of costs from doctors against whom complaints have failed, and other matters to which attention has been drawn from time to time. In the second place they have been unable to forget that in this country every citizen enjoys an unfettered right of access to courts of justice, and they have resented the apparent diminution of that right in the contractual relationship which governs their service under the National Health Insurance Acts. As a result of recent discussions the position of the panel doctor has been improved and the atmosphere cleared. He may be congratulated on having obtained valuable concessions. The Ministry of Health has consented to allow him the opportunity of a further hearing before any lesser penalty than removal from the medical list is inflicted.

Thus a doctor summoned to meet definite allegations on the issue whether his name is to be removed or not, and who has succeeded upon that issue, is not to be punished upon other issues without a proper chance to make his defence. Secondly, the Ministry has expressed—though rather cautiously—its willingness to consider evidence of the previous good character and professional reputation of a practitioner. Thirdly, the Ministry has recognised that, in considering whether reasonable skill and care have been exercised, the question necessarily involves medical issues on which the guidance of professional advice is required. The Minister is prepared to accept nominations by the Insurance Acts Committee of a small panel of practitioners from which could be selected those whose advice might be sought in particular cases. This offer, on the unanimous approval by the Panel Conference (reported at length on p. 909 of our present issue) of a motion by Dr. H. G. DAIN to that effect, has been referred to the Committee for discussion with the Ministry. The Ministry has hitherto shown itself disinclined to enlarge its recourse to a professional tribunal on points of professional practice—an attitude in contrast to that of the Home Office which has recently had sufficient confidence in the medical profession to entrust its representatives with a remarkable measure of criminal jurisdiction under the Dangerous Drugs Acts. As Dr. DAIN observes, the Ministry's offer to insert a professional tribunal somewhere in the machinery of health insurance is a step in the right direction, but it is not yet clear at what point the tribunal will be inserted. These concessions will do much to meet the demand for a right of appeal to the law-courts, though we have yet to see them in operation. We must not be thought ungrateful for them if we suggest that the Ministry would remove a great source of grievance if it would limit its disciplinary decisions to the sole question whether a panel doctor is or is not fit to be upon the medical list. When exercising its own disciplinary jurisdiction the General Medical Council confines itself to the single issue whether a registered medical practitioner is or is not fit to be upon the Register. The feeling is growing that it would better accord with the traditions and dignity of the profession if the Ministry worked upon the same basis and eschewed the imposition of lesser penalties.

Upon the general question of the right to appeal to the law-courts it is wise not to confuse two very different matters. The possible appeal from a disciplinary decision of the Minister under the health insurance system is something quite distinct from the possible appeal against a disciplinary decision of the General Medical Council. As we have on other occasions observed, the members of various professions—nurses, midwives, dentists, and veterinary surgeons—have a statutory right of appeal to the High Court or the Privy Council against the removal of their names from the professional register; medical practitioners have no such statutory right. But this disability of doctors to appeal against a disciplinary tribunal composed of members of their own profession has an aspect very different from the disability to appeal against the disciplinary decision of a Government department. It may fairly be said that the doctor's sense of exclusion from the law-courts in the one case makes him more conscious of exclusion in the other; but no useful purpose is served by confusing the two disabilities. Nor should too much stress be laid, we consider, on the grievance that a panel patient, in addition to the right of complaint under the Medical Benefit Regulations, has access also to the law-courts to obtain damages for alleged negligence on the part of the panel doctor. The patient has a right to enforce in the courts the supposed duties of the panel doctor. There are no converse duties on the part of the panel patient which the doctor needs to enforce. The legal position is thus in this respect not so one-sided as it might at first appear. When these considerations have been eliminated there remains to say that the Ministry of Health will more readily reach the successful solution of present difficulties by avoiding emphasis on doubtful arguments of its own. It is no final answer to say that a proposed reform will involve fresh legislation. That is what Parliament is for. Nor is it conclusive to suggest that the right of appeal for which panel doctors are pressing will involve expensive and cumbrous proceedings. The ordinary litigant does not find it either a cheap or a precipitate process to take his grievance from the lowest courts up to the House of Lords; yet nobody suggests that his right of appeal should therefore disappear. The Ministry must not make too much either of its suggestion that the British constitution forbids an appeal to the law-courts from the decision of a department, or of its hint that the panel doctor must not take his troubles to a judge because these are matters of high policy fit only for the Government or Parliament to handle. Distinguished judges have commented adversely upon the growing tendency of departments and officials to claim to act without appeal to a court of law, and sound constitutional doctrine teaches that the amalgamation of judicial and executive functions is a grave political danger.

CLINICS FOR RHEUMATISM.

THE immense amount of industrial disability produced by rheumatism is only just beginning to attract the attention that it deserves. Attempts have lately been made to interest both employers and trades unionists in the magnitude of the problem; the friendly societies have already shown their concern, whilst early in the present week Mr. SPEDAN LEWIS, a big employer of labour in London, presided at a meeting promoted by the Citizens' Council of the Federation of Medical and Allied Services, at which Sir THOMAS HORDER opened a discussion on rheumatism in industry. Recent inquiry in the insurance medical service has shown that 370,000 insured patients annually seek medical advice on account of rheumatism; that two million pounds are given to these patients for subsistence (not for treatment), and that three million weeks of work are thus forfeited each year. The spa hospitals have 681 beds between them and treat about 8600 patients in the year. Outside these hospitals there is no adequate treatment for insured persons suffering from rheumatic disease, for, as Dr. M. B. RAY states in a paper printed in the present issue of THE LANCET, the treatment available at hospital out-patient departments is usually not of the kind likely to prove most beneficial. In this we might learn a lesson from one of our nearest neighbours. Reviewing the measures taken in Northern Europe for the treatment of industrial rheumatism, Dr. RAY refers to Dr. J. VAN BREEMEN'S clinic at Amsterdam, which has just been visited by representatives of the Ministry of Health, where about 1000 patients are dealt with every year and various kinds of physical treatment are given with no little success. Dr. RAY describes the suggestions of an English subcommittee of the International Society of Medical Hydrology. Their scheme provides in the first place for the proper selection at distributing centres of cases for special treatment. At the present time it is the advanced cases, for whom little can be done, which are chiefly to be found at spa hospitals, while the less advanced and more hopeful cases frequent the surgeries of insurance practitioners at stated intervals simply in order to obtain the renewal of their certificates of disability. Unfortunately, the more obvious and permanent the disability the better the chance of securing admission to a spa hospital. Their second aim is the further investigation of rheumatism as a pathological condition into whose causation a great many factors may enter. And in the third place the committee aims at setting up further centres for the actual treatment of rheumatic conditions; these are to take the form of clinics for physical and other therapy in large towns, the possibility of attaching wards to these clinics being borne in mind.

It will be generally agreed that the present lack of treatment of chronic rheumatism is a drain on the industry and resources of the country; industries, friendly societies, and the Government would all serve their own interests by spending a little more money on treatment than they now spend on a subsistence dole. A recent friendly society conference has called on the Ministry of Health to sanction spa treatment as an additional benefit under the National Insurance Acts, and there is reason to suppose that their plea will be successful, though it is not so clear that there will be funds available to make it effective. Moreover, though we may agree with Sir KINGSLEY WOOD'S remark at Leamington that British spas bear comparison with any of their foreign rivals, the facilities for distributing patients to the proper centres and giving them proper treatment leave much to be desired, and if insured persons are to derive full advantage from the benefits of spa treatment, it will certainly be necessary to provide centres for diagnosis. The suggestion is that diagnosis should be done at clinics, but nowadays examination of a case of arthritis involves exhaustive investigation along bacteriological, metabolic, clinical, and other lines and is hard to carry out without keeping the patient in bed for a while. From the point of view of research into ætiology, also, the clinic would probably prove less suitable than the large hospital.

Though, however, we may question whether the out-patient clinic is the ideal unit for distributing patients and for research, there can be no doubt of its therapeutic usefulness; it is clear enough that an immense amount of industrial disability (and of suffering) could be saved by palliative treatment given on a large scale at clinics all over the country, in a way that it is not given at the present time. It may be that at some hospitals the physical treatment departments are providing the best that can be had, but there are not enough of them, they are not properly supported, and do not receive the right patients at the right time. The need is rather for reorganisation of existing facilities than for a new departure likely to alter medical methods or bring valuable scientific information. But in view of the seriousness of rheumatism this reorganisation is exceedingly important. The problem of chronic arthritis in adults cannot be tackled by the individual practitioner; it is not being tackled by the hospitals, and it seems that it could be tackled by clinics. The specialist clinic is a necessary development of insurance practice and, as the Dawson Report pointed out, it is by clinics that much of the medical work of the future will have to be carried on. Rheumatic disability in its milder forms seems particularly fitted for treatment at this type of institution; suitably organised such treatment might be given to patients without preventing them from carrying on with some at least of their work. Local treatment (e.g., radiant heat) and advice about diet and clothing may be enough to convert the discouraged certificate-holder who loafs at home into a patient who is hoping to get well and is able to go on with his work. To sum up: elaborate hospitals may be needed for investigation and distribution of cases, but much good might be done by palliative treatment at clinics, of which many would be needed. Whilst these clinics may carry on research in therapeutics, they are not, perhaps, so likely to prove valuable in research on ætiology.

PUBLIC HEALTH IN GERMANY.

LAST week, under the auspices of the Chadwick Trust, Prof. Rudolf Abel, of the University of Jena, gave two lectures in London on the Development and Present State of Public Health in Germany. We have already briefly reported the first of these lectures,[1] which was given on Oct. 19th, with Sir William Collins in the chair, and have referred to Prof. Abel's intention to compare the conditions and history of public health work in Germany and England. This theme was pursued by Sir Arthur Newsholme, who presided on Oct. 20th, and pointed out that the English development arose largely from humanitarian motives, though economic motives also had their influence, whereas the more recent German impulse started in the laboratory, in the work of Pettenkofer, and later in that of Koch and many others. Prof. Abel's second lecture was a survey of almost the whole field of public health and social work. He said that the German

[1] THE LANCET, Oct. 23rd, p. 886.

law, which requires vaccination in infancy and at the age of 12, is strictly enforced, there being no conscientious objection. As in England, coincident with enforcement of vaccination, there has been the well-known inversion of the age-incidence of small-pox; up to 1874 nearly all deaths from this disease occurred at ages under 12, whereas in 1916–17 90 per cent. occurred at ages over 40, and a large proportion of the small number of deaths occurred among foreigners. In Germany no fees are paid to doctors for notifying cases of infectious disease, this being regarded as a duty they owe to the State. There is more typhoid in Germany than in England, but very much less measles. The tuberculosis death-rate, although always higher than in England, shows an almost parallel course of decline. Dealing with tuberculosis, venereal disease, and alcoholism, which he called "the three national scourges of Germany," Prof. Abel said that in Germany there are 186 tuberculosis sanatoriums for adults with some 20,000 beds, 318 sanatoriums for children with some 27,000 beds, 183 open-air schools, and 444 hospitals and homes for tuberculous patients. The success of the various methods of treatment and advice at these institutions, in dispensaries, and at the homes of the patients is obvious, though still inadequate The increase in the death-rate from tuberculosis during the late war was greater in Germany than in England; and after a post-bellum decline there was a smaller but significant rise once more in 1923–24, during the privations involved in the so-called demonetisation of German finance. Venereal diseases also increased greatly in war-time. In 1909 a census was taken of patients under treatment for these diseases. For Germany as a whole the proportion at the time of the census was 20, and for the large towns was 80 per 10,000 inhabitants. During the war there was some provision for compulsory treatment of patients, which has not been continued, and at the present time the prohibition of treatment by quacks, already enforced in England, is under consideration. The alcoholic question, Prof. Abel pointed out, is one of serious public health import. Before the war the expenditure per head on alcoholic drinks was 45*s.* a year, but during the war it fell greatly, as also did admissions to lunatic asylums for alcoholism. The lecturer spoke strongly of the need for further regulation of the consumption of alcohol, and for the encouragement of sport and other counter-attractions.

In the important work of maternity and child welfare much work has been done in Germany, and in Prof. Abel's opinion midwifery is on the whole better regulated than in England. Abortion, however, has greatly increased in recent years and infant mortality is higher than in England. Thus in 1925 the infantile death-rate in Germany was 105, but in England only 75 per 1000 births. The school medical service on the average is less developed than in this country, but all children are examined at the time of entering and on leaving school. Medical supervision is being gradually extended to the continuation schools, which must be attended by all children up to the age of 18. The general use of hospitals almost dates from 1869, when Lister initiated the antiseptic treatment of wounds. Prior to this the view held in Germany apparently was that of Florence Nightingale—namely, that hospital treatment greatly increased the chance of death. Most hospitals are now supported out of public funds, and there are no separate hospitals for infectious diseases, even small-pox being treated in rooms off the general wards. The number of hospital beds available in Germany is stated to be over 5 per 1000 inhabitants. In housing and town-planning it is evident that Germany has progressed much less than England. Town-planning Prof. Abel regarded as being of French (Napoleonic) origin, while for the initiation of underground sanitation (water-supplies and sewerage) Germany is indebted to England. Town-planning as carried out both in France and Germany in central sites has been mischievous, he thinks, because owing to the uncontrolled price of these plots of land, it has been necessary to crowd tall houses on each plot. Over 46 per cent. of the population of Berlin live in one or two rooms, the corresponding figure for Edinburgh being, it was stated, 36 per cent. Lantern slides were shown to illustrate the customary five- and six-storey tenement dwellings, and were reminiscent of the worst conditions of New York; in Berlin on an average 76 families, and in Munich 39 families, live in each block. After the war a million German refugees returned from other countries, and owing to cessation of all building operations the housing position in Germany became desperate. There has been fixation of rents, as in England.

In the last section of his rapid review Prof. Abel made some general remarks on the transition from environmental hygiene to personal hygiene, quoting with approval the saying that environment holds the organism in its grip and hammers it into shape; he described some of the many attempts to shape personal life which are now being made in Germany as in other countries. It is evident, however, he said, that England has gone further and has had greater success in this, as well as in environmental hygiene, than the German Empire, though for part of this difference the pitiable financial position of the mass of population of Germany is partially responsible.

The Chadwick Trust are to be congratulated in securing for the English public access to the lucid and accurate information which Prof. Abel was able to give in his two lectures.

CIVIC HEALTH WEEKS.

AN October week has been chosen by many municipalities in the British Isles to bring to the notice of all good citizens the efforts made on their behalf to render life clean and healthy. We call attention on another page to the well-designed and executed booklets issued by the health committees of St. Pancras and Kingston-upon-Hull. Dr. SOWDEN'S idea is to provide a homely work of reference for parents so that they may avoid the common mistakes and risks in the upbringing of children. Dr. DALEY arranged an open day at the maternity home, welfare centres and after-care colonies, with a variety of health films at the local kinemas. In Dublin, under the auspices of the Women's Health Association, the secretary of the new Department of Local Government and Public Health addressed a large gathering on the advantages already gained from cleanliness in a big sense and foreshadowed a scheme for the medical inspection of school-children in Ireland. In Liverpool the celebration of "Civic Week" was so successful that it is likely to become an annual event. Here we may have a great potentiality for good as yet largely untapped. If "Civic Week" becomes an institution adopted in other large towns it is essential that due importance should be attached to the medical aspects of a city's life and greatness. Few laymen realise how all-pervading are the activities of the medical officer of health's department, nor how much they are indebted to his staff for the safety, cleanliness and comfort of the daily round. Properly utilised, such an occasion could be made most telling in the diffusion of elementary facts of hygiene, by lecturettes, exhibition of lantern and kinematograph films, and by demonstrations of certain phases of sanitary work in actual progress.

CONFERENCE ON THE CARE OF CRIPPLES.—A joint conference on the care of invalid and crippled children is to be held by the Invalid Children's Aid Association and the Central Committee for the Care of Cripples on Thursday and Friday, Nov. 18th and 19th, in the great hall of the British Medical Association in Tavistock-square. Mr. Neville Chamberlain, Minister of Health, will give the opening address, and the chair will be taken at the four sessions by Lord Islington, the Duchess of Atholl, M.P., Sir Arthur Stanley, and Sir Robert Jones. Among the medical speakers will be Mr. R. C. Elmslie, Mr. Harry Platt, Dr. Stuart Cowell, Dr. Arbour Stevens, and Mr. G. R. Girdlestone. Further particulars may be had from the hon. secretaries of the Association and Committee at 117, Piccadilly, London, W. 1. The sessions will begin at 10.30 and 2.30 on each day.

Annotations.

"Ne quid nimis."

GASTRIC ULCER AND GASTRIC CANCER.

A GREAT deal has been written about the relation of gastric cancer to gastric ulcer, and very different opinions have been expressed. It is a hackneyed subject to which there would be no object in referring—unless new data could be brought forward—were it not that the declared high incidence of cancer grafted upon simple ulcer in the stomach is used by some surgeons of authority as a strong argument in favour of submitting the patient with gastric ulcer to an excision operation of some severity. Belief in the reality of the high occurrence rate of this terrible complication must necessarily often be the deciding factor in arriving at the grave decision to perform an extensive gastrectomy. It is therefore not unfitting that from time to time attention should be directed to such an important but still debatable question, and on p. 925 we publish a letter from Dr. Alfred Plaut, who reviews very unfavourably the evidence accepted by many in support of the claim that gastric ulcer frequently ends in gastric cancer. He points out the fallacies in many statistical publications. Particularly worthless, he considers, is the long history of indigestion which sometimes precedes cancer, for not only may simple dyspepsia vitiate such statistics, but in a number of instances it has been proved that cancer of the stomach may follow a very prolonged course. In the earliest stages it is symptomless, and so remains unrecognised for a period, the length of which is unknown. Dr. Plaut declares that reliable hospital statistics show unrecognised cancer of the stomach to reach as high a percentage as 20. The commonest site of cancer, he points out, is not the commonest site of ulcer. This latter disease has a peculiar geographical distribution, some countries or districts in the same country showing a much greater incidence than others. Cancer shows no parallel distribution as it should do were there an important relation between the two diseases. Whilst not denying that very rarely cancerous change appears in a simple ulcer, Dr. Plaut goes the length of saying that the belief that it is a more common event is a matter of psychology, a simple assertion or affirmation, and does not arise from a purely medical decision.

A summary of the true medical evidence may be given. In 1914 W. C. McCarty and A. C. Broders [1] from histological investigations said that the incidence of malignant transformation was 70 per cent. This figure has been questioned by J. Ewing [2] and by B. H. Spilsbury,[3] who lay stress on the fact that, at the margin of a simple ulcer, distortion of the epithelial arrangement is caused by fibrosis and can easily be mistaken for cancer. J. H. Dible [4] did not find a single undisputable case amongst 126 excised ulcers, neither did J. Morley [5] find a case amongst 50 resected ulcers. Berkeley Moynihan,[6] partly from consideration of the history, but partly from the researches of M. J. Stewart [7] at Leeds, who gives the incidence as 9·6 per cent. in the material submitted to him, believes cancer to be a not uncommon complication of gastric ulcer. H. Finsterer [8] found cancer in 26·6 per cent. of 175 resected callous ulcers; C. A. Pannett [9] in 10 per cent. of 41 resected ulcers, and V. Orator [10] in 30 per cent. of ulcers of the prepyloric region and 2 per cent. of ulcers situated elsewhere.

It can be regarded as certain that later statistics are not vitiated by the fallacy of regarding innocent, but disordered, growth at the fibrosed ulcer margins as malignant, and it may therefore be asked why some surgeons have found no examples of cancerous change in their resected material, whilst others give an incidence ranging between 10 and 30 per cent. The explanation is not far to seek. Every simple ulcer which exhibits malignant change is of the callous type. Such ulcers form adhesions to neighbouring organs into which they burrow so that their excision often becomes a matter of some considerable difficulty. Those surgeons who confine their resection operations to mobile ulcers will meet with a low cancer incidence in their material, whilst those who excise the callous adherent lesions will get a truer picture of what the real risk of malignant change is. The chance of malignant change is greater when the ulcer is near the pylorus, perhaps indeed as high as 30 per cent., but in general the risk of a gastric ulcer becoming cancerous would seem to be about one-third of this. As to the question whether this risk justifies extensive gastric resections, the answer can only be in the affirmative, as 10 per cent. is very considerably greater than the operative mortality of gastric resection, whilst subsequent cancer is only one of the less important causes of death in a patient suffering from gastric ulcer. After a properly performed partial gastrectomy the recurrence of symptoms from ulcer is a rarity.

A HOSPITAL CENTRE FOR BIRMINGHAM.

IMPORTANT developments are announced in connexion with hospital policy in Birmingham—developments which put a new face on the situation. The General and the Queen's Hospitals had prepared and begun to carry out comprehensive plans for extension. The General Hospital had obtained by Act of Parliament the neighbouring St. Mary's churchyard for the purpose of a new out-patient and casualty department, and the Queen's Hospital had already erected new buildings. The Hospitals' Council, however, lately asked that these schemes should be suspended in order that the problem might be considered from a wider standpoint, and the governing bodies of the two institutions were invited to form a joint committee to consider the outlines of a scheme for a new hospital centre. This committee has now issued an important report which has received the approval of the boards of the two hospitals and of the Hospital Council. It is recommended that a new hospital centre shall be established on a site adjoining the University at Edgbaston, under the joint control of the General and Queen's Hospitals. To this end it is proposed that the two hospitals shall be amalgamated for all purposes and that the new hospital shall start with a minimum of 750 beds—a number based on the calculation that by 1931 a minimum of 2400 beds for general medical and surgical patients will be needed by the city, including those provided by the guardians of the poor as well as by voluntary boards. This ambitious and far-reaching scheme has been brought into the region of possibility by the generous gift of Messrs. Cadbury Brothers, which we reported last week (THE LANCET, Oct. 23rd, p. 884). Messrs. Cadbury offer to give the City Council 150 acres of land adjacent to the University, together with a donation of £5000 towards the initial expenses of laying out the site. The whole of the land is to become the property of the city, on the understanding that the City Council, in consultation with the Hospitals' Council, shall reserve 100 acres with power to grant long leases to the hospital authorities at a nominal rent, and it is hoped that the City Council will make the necessary roads and be responsible for the lay-out and maintenance of the remainder of the land for use as playing fields, which some of the schools urgently require. The council, needless to say, has gratefully accepted Messrs. Cadbury's offer, for the site has been admirably chosen as standing on high ground in the south-west of the city and on the confines of the pleasant residential suburb of Edgbaston. Though well away from the centre of the city it will be well served by railway, electric tram, and 'bus routes, and

it is just beside the University. At present the medical school is housed in the Mason College building in the centre of the city, and the clinical work is divided between the two general hospitals. Under the new scheme it is intended that new buildings for the medical school shall be erected in conjunction with the hospital, so that the whole of the work of the school—theoretical and practical—can be undertaken in a group of buildings on the same site. Formidable financial obstacles have yet to be surmounted before the great project can be accomplished, but the City of Birmingham has now the opportunity of founding a real hospital centre with ample space for development.

SCARLET FEVER AND STREPTOCOCCI.

RECENT results have gone far to show the correctness of the view that streptococci are the causal organism of scarlet fever. Most of the work on the subject has been done in this country and America, and it is therefore interesting to read results obtained in Tunis by that accomplished experimenter C. Nicolle, who, in collaboration with E. Conseit and P. Durand, has investigated the same problem.[1] Their experiments were for a long time directed towards the reproduction of the disease in animals by means of an assumed filtrable virus, whose presence they suspected in secretions and exudates. No positive results followed, although the attempts were numerous and various species of animals were employed. Concluding that scarlet fever did not lend itself to animal experiments, the investigators made attempts—necessarily restricted—to inoculate human subjects; but these attempts likewise failed. At this stage the work of the Dicks became known, and the conclusion was reached that the failures were due to the employment of immune subjects, and that their repetition on subjects selected by the Dick test might give other results. Not having the Dick toxin at hand, the workers in Tunis attempted to test for susceptible individuals by using the urine of a patient suffering from the disease, which afforded, in this case, a cutaneous reaction. By this means two susceptible individuals were selected. A third person, not tested for susceptibility, was inoculated in the tonsil with a fragment of tonsillar tissue from the scarlatinal patient and developed a severe sore-throat without the typical eruption. A culture of streptococci from the scarlet fever patient, in the fourth generation, was introduced into one tonsil of one of the susceptible persons with the result that a typical attack of the disease occurred after six days' incubation. The second susceptible subject was injected subcutaneously with a half c.cm. of the urine (which served, as we have said, as the Dick toxin); two days later this subject showed a generalised scarlatinal eruption and pyrexia, which the authors interpret as a specific toxic phenomenon. These experiments are few and open to objection; but it is of some importance that every observation bearing upon this problem should be recorded, and especially those in which genuine scarlatina appears to have followed inoculation with cultures of streptococci.

RESEARCH IN DAIRYING.

SINCE the National Institute for Research in Dairying was first established at University College, Reading in 1912, the work undertaken there has developed year by year. The Institute now comprises three main sections: dairy husbandry, chemistry, and bacteriology, coördination being secured through the agency of a professional committee, consisting of the heads of departments and certain members of the Faculty of Agriculture. Under the first section a number of different problems connected with the management and feeding of dairy stock have been tackled, including work on calf rearing and the detection of abnormal and vegetable-tainted milk. The chemical constitution and other properties of milk have presented a variety of more or less complicated problems. Studies have been made on the coagulation properties of milk and on calcium metabolism; physico-chemical methods have indicated the very significant part played by caseinogen in the control of the secretion of calcium in milk. The effects produced by very large doses of certain inorganic salts on the calcium content of the blood and of the milk of lactating cows have also been investigated; it appears to be difficult by such means to effect any significant alteration in these constituents or in the yield and composition of milk. The close inter-relationship of these problems is illustrated by the part played by the calcifying vitamin (vitamin D) in calcium assimilation and in the resulting calcification of the bones. A cow fed on a diet lacking in fat-soluble vitamins will deplete her skeleton to the extent of one-quarter of its calcium content in the endeavour to make up calcium-deficiencies in her milk. Experiments have been conducted on the vitamin content of the butter made from the milk of stall-fed cows in winter time. It has been demonstrated that such feeding may reduce the vitamin content of the butter to one-tenth of its summer value, but that the summer value in vitamin A may be obtained by adding cod-liver oil to the ration, the butter still remaining white. Other experiments have shown that there are differences in the vitamin content of winter foods in common use; for example, meadow hay is richer in these factors than seeds hay. The influence, if any, of the vitamin content of the food on the yield and composition of the milk is being investigated. Among other problems which have been solved by the Institute is the question of ropy milk. This has been shown to be due to at least two entirely different causes: the physical type of ropiness which appears when the milk is passing over the cooler and is not present in the bulk milk in the churn, and the more generally recognised type which causes the bulk milk to become ropy and which is due to the action of bacteria. Courses of "clean milk" instruction and demonstration are arranged by the Institute every year, a great deal of advisory work among farmers also being carried out. But the work of the Institute is still handicapped by lack of funds.

THE JUBILEE OF PROFESSOR SCHMIEGELOW.

ON Oct. 13th Dr. Ernst Schmiegelow, professor of oto-laryngology in the University in Copenhagen, celebrated his seventieth birthday by delivering his last lecture at the Rigshospital, thus finishing his active career there both as head of the clinic and as professor of his specialty. That he is not without honour in his own country was shown by the manifestations of esteem and regard from his townsmen and compatriots, who presented him with a striking portrait of himself painted by the well-known Danish artist, Henningsen. In addition, the brotherhood of laryngologists in other lands united to present him with a bas-relief portrait in bronze, by the Swedish artist, Gosta Carrell. This had been subscribed for by friends and admirers from many countries, under the leadership of Prof. Gunnar Holmgren (Stockholm), who, in their name, presented it to the Throat Clinic of the Rigshospital. In addition to numerous colleagues from Sweden and Norway the following laryngologists, among others, were present in testimony of the international character of the occasion: Profs. H. Burger (Amsterdam), H. Marschik (Vienna), G. Spiess (Frankfurt), C. von Eicken, L. Kuttner, and E. Flatau (Berlin), and Sir StClair Thomson (London). The foreign delegates were welcomed with much private hospitality. A special meeting of the Danish Oto-Laryngological Society was held on the previous day, presided over by Dr. Strandberg, when by invitation three communications were made. Prof. Burger spoke on the Education of the Partially Deaf Child. Prof. von Eicken read a paper on Indications for Operation in Sinus Disease, and Sir StClair Thomson gave a

lantern demonstration of Technique and Results of Laryngofissure in Intrinsic Cancer of the Larynx. Dr. Strandberg is connected with the Finsen Institute at Copenhagen and will read a paper at the Royal Society of Medicine on Friday, Nov. 19th, before the Tuberculosis Society, the subject being the treatment of laryngeal tuberculosis by heliotherapy and artificial light.

MONOCYTES AND BACTERIAL INFECTION.

A GENERAL view of the specificity of leucocytoses leads to the conclusion that eosinophile cells are stimulated by worms (trematodes, cestodes, and nematodes living in the bowel, blood, or tissues) and large mononuclears by protozoa (whether hæmamœbæ, trypanosomes, spirochætes, or the virus of chicken-pox), while bacteria, if they excite any leucocyte, stimulate neutrophiles. Lymphocytes and basophiles are not known to respond to any acute parasitic infection. It is therefore of much interest to find an organism, which appears undoubtedly to be a bacterium, and yet causes characteristically and constantly a high grade of large mononuclear leucocytosis. An unexplained mortality among the stock rabbits of the Cambridge pathological laboratory was investigated by Dr. E. G. D. Murray in conjunction with Dr. R. A. Webb and the late Dr. M. B. R. Swann,[1] and after some trouble a small Gram-positive bacillus was found in the organs and isolated in pure culture; with it the disease was reproduced, and especially in sublethal doses a considerable leucocytosis, due exclusively to an increase in the large mononuclears, was regularly produced. The organism does not appear to have been described before, and the authors, falling into the easy fallacy of definitive names, have called it *Bacterium monocytogenes*. Its characters are of technical interest, but curiously enough Dr. Harvey Pirie has recently found the same microbe in a gerbille in South Africa. Dr. Murray and his colleagues describe also some experiments which emphasise the specificity of leucocyte response as clearly as Ehrlich's old observation that pyogenic infection in a person with a high grade of eosinophilia in the blood excites neutrophiles and not eosinophiles. On intrapleural injection of broth or *B. coli*, the cells of the resultant exudate were mostly polynuclears even when the blood showed a high mononuclear leucocytosis due to a previous infection with *B. monocytogenes*. If under the same conditions *B. monocytogenes* was injected into the pleura, the exudate contained large numbers of mononuclears. They also show that large mononuclears, which are poor phagocytes for bacteria in general, will eat their new bacillus as actively as neutrophiles.

A YORKSHIRE CANCER PAMPHLET.

THE Medical and Scientific Committee of the Yorkshire Council of the British Empire Cancer Campaign, under the chairmanship of Sir Berkeley Moynihan, has issued an attractive little volume of 75 pages entitled "Notes on Cancer for Medical Men." The chief object is to preach the gospel of "early diagnosis and early operation" as the only effective means of fighting cancer. The main part of the book is taken up with a short and clear account of the clinical aspects of cancer in the different sites of the body; the fact is emphasised that cancer in its earliest stage is a local disease and can then be certainly cured by operative removal. These two fundamental statements can be made to-day with the certainty given by experimental evidence, and it seems a pity that in the chapter on experimental cancer research this point has been completely missed. Two short statements are appended intended to educate the public on cancer, and separate copies of these will be given to any medical man desiring to distribute them among his patients. They are clearly written and could hardly be bettered. In the introduction to the "Notes" the statement is made that cancer is neither infectious nor contagious; the same statement has been issued by the Cancer Conference in Mohonk. There is, of course, general agreement that cancer is not contagious. But if Gye's view, which is referred to in the book, is correct and a living virus plays a part in the ætiology of cancer, cancer must be considered as an infection; it seems inadvisable that in a book of this kind those aspects of the cancer problem which are still the object of active investigation should be prejudiced by statements which might be misinterpreted. We are asked to state that a free copy may be obtained by any medical man free on application to the office of the Yorkshire Council, 47, Park-square, Leeds. The "Notes" are certainly worthy of a wide circulation.

THE PREVALENCE OF POLIOMYELITIS AND POLIO-ENCEPHALITIS.

THERE is a normal increase in the autumn each year of reported cases of poliomyelitis and polio-encephalitis, but the increase this year has been larger than usual, and groups of cases have occurred in several areas. We have already given[1] some details of the outbreak in Leicestershire, with special incidence in Leicester itself where 73 cases have been reported up to the present, a considerable number in older children and some in adults, and where half a dozen deaths, chiefly of the fulminating type, have occurred. Dr. C. K. Millard then stated that no more than a single case had occurred in any one house, and that practically no connexion between the cases had been traced. He suggested that under normal conditions the milder cases of poliomyelitis are apt to escape notification. In the week ending Oct. 16th, 62 cases of acute poliomyelitis and 16 cases of acute polio-encephalitis, 78 taken together, were notified from England and Wales, the counties reporting more than three cases being Kent 23, Leicester 8, and Middlesex 5. The outbreak in Kent has been practically confined to Canterbury and Thanet, where an ill-founded rumour of encephalitis lethargica at first gave rise to alarm. In Broadstairs 53 cases were notified between Oct. 14th and 25th, most of them of a mild type, only two deaths having occurred among them. The local sanitary authority of Broadstairs has issued a circular in which it is stated that the disease is carried from person to person, infection being taken through the nose and mouth, but, so far as is known, not carried by water or milk. Warning is issued against the gathering of children together; no child, it is said, should be allowed to enter any house where there is a case of sickness; the sick should be isolated from the healthy, and if strict isolation and appropriate nursing cannot be obtained at home the patient should be treated in the isolation hospital. Those who have been in contact with the sick should be isolated for three weeks, and the patients themselves for six weeks. Persons brought into contact with the patients are advised to disinfect nose and throat with antiseptic solution (pot. permang. 1 in 4000 normal saline, or hydr. perox. 1 in 100) by spray or snuffing from the palm of the hand, done in the first instance under medical supervision.

Dr. Robert Cunyngham Brown, C.B.E., who has been appointed a Commissioner of the Board of Control to fill a vacancy caused by the retirement of Dr. Robert Welsh Branthwaite, C.B., was Deputy Commissioner to the Board of Control for Scotland before accepting the position of Deputy Director-General of Medical Services at the Ministry of Pensions. Some of his earlier writings on the causation of nervous disease appeared nearly 30 years ago in our own columns.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXCV.—THE TREATMENT OF TRACHOMA.

TRACHOMA is a chronic contagious disease in which such acute manifestations as occur are the result of superadded infections with well-known bacteria. The cause of trachoma itself is as yet uncertain. It manifests itself in many widely differing forms, all of which are stages in the evolution of the disease, each stage requiring appropriate treatment.

The disease is conveniently divided into four stages, known as trachoma I., II., III., and IV., according to the comparative prominence of the three features—follicles (or granulations), papillary hypertrophy, and connective tissue formation.

In Trachoma I., seen soon after infection has occurred, tiny grey pinhead follicles are sparsely scattered on the conjunctiva of the upper tarsus. Trachoma II. has three subdivisions: (*a*), in which enlarged follicles predominate; (*b*), in which a papillary hypertrophy coexists with the follicles (this subdivision is split up into trachoma II. (*b'*), which is unmixed trachoma, and trachoma II. (*b''*), which is trachoma complicated by spring catarrh); (*c*), in which trachoma is complicated by a superadded infection with the Koch-Weeks bacillus, or the Morax-Axenfeld bacillus, or the gonococcus (a common non-venereal conjunctival infection in the Near East). Trachoma III. is the stage in which cicatrisation has begun. Trachoma IV. is cured trachoma, in which cicatrisation is complete.

Trachoma I.

This stage may be present without causing any symptoms and without producing obvious signs until the lid is everted, when tiny pinhead follicles are seen on the conjunctiva of the tarsus and at the retro-tarsal fold, more rarely in the fornix. With a lens or slit lamp may be seen a system of blood-vessels invading the cornea, associated with tiny follicles between the corneal epithelium and Bowman's membrane.

Treatment of trachoma at this early stage is begun by the application of silver nitrate solution 2 per cent., rubbed on the everted lids daily with a pledgelet of cotton-wool wound round the end of a special glass rod. The cotton-wool must be of good quality or it will be impossible to make a neat brush. A fresh rod is used for each eye; after use it is placed in an antiseptic solution and left there until it can be sterilised by boiling. If several patients are being treated the rubber gloved hands should be immersed in an antiseptic solution such as perchloride of mercury, 1 in 1000, in 70 per cent. spirit. The action of silver nitrate is not imitated by the organic silver compounds, such as argyrol, protargol, and others. If, when the patient is next seen after a rubbing, there is any coagulum or necrotic material remaining, the next treatment should be postponed until the slough has separated.

If there is much discharge this treatment should be carried out twice a day. The eyelids and the conjunctival sacs should also be bathed with a solution of perchloride of mercury, of a strength, for adults 1 in 5000, for young children 1 in 10,000. The eyelids should be anointed nightly with some ointment.

This treatment must be continued for many months. Under its influence the trachoma follicles may become absorbed without leaving any trace of cicatrisation; more usually, however, faint lines of cicatricial tissue are left (stage IV. of the disease). In the majority of cases the treatment is not continued for a sufficiently long period, and trachoma I. passes into II. or III.

It is not necessary or even advisable to neutralise the silver nitrate after its application with salt solution, as this is done quite efficiently by the tears. It is advisable to vary the treatment from time to time. Instead of silver nitrate, cyanide of mercury 1 per cent., copper sulphate 10 per cent., perchloride of mercury ½ per cent., may be employed. In addition, the instillation t.d.s. of zinc sulphate ½ per cent., or zinc chloride ¼ per cent., may be useful.

It must be remembered that many cases of trachoma pass into the cured stage IV. without treatment of any kind and without any complications; also that monocular trachoma is not uncommon. Treatment by means of a pencil of carbon dioxide snow in this stage may be satisfactory. It must be applied with considerable judgment or serious scarring may result. Treatment by means of radium has in my hands been unsatisfactory. Local phototherapy for trachoma has been employed experimentally by means of the mercury-vapour lamp suitably screened acting on the everted lids.

Surgical treatment is not usually indicated in trachoma I.; however, radical cure of the disease may occasionally be attempted, when it is confined to the conjunctiva of the upper tarsus, by means of removal of the tarsus with the diseased conjunctiva overlying it. Subconjunctival injections behind the retro-tarsal fold have been employed. They are attended with considerable inflammatory reaction, and should only be used by specialists.

Trachoma II.

In trachoma II. (*a*) the gelatinous follicles are ruptured, mechanically allowing the escape of their contents. This may be carried out by means of Graddy's forceps assisted by a curette. Excessive bleeding is prevented by thoroughly bleaching the conjunctiva beforehand with adrenalin chloride solution, 1 in 1000. A general anæsthetic is frequently necessary, though in a large number of cases a thorough infiltration of the lids with novocaine solution 1 per cent., with instillation of 4 per cent. cocaine hydrochloride into the conjunctival sac is quite adequate; 10 or 15 minutes must be allowed for the anæsthetic solution to act.

The upper lid is everted and Graddy's forceps are applied to the everted conjunctiva and withdrawn, carrying in front of their concavity the gelatinous contents of the follicles which are ruptured by the passage of the instrument. If follicles are present in the fornical conjunctiva, previous to using Graddy's forceps the retro-tarsal fold should be seized with a pair of toothed forceps in order to allow of the lid being re-everted; the fornix is then curetted. The lower lid should be curetted, since unless the conjunctiva is loose Graddy's forceps are not applicable.

Perchloride of mercury solution, 1 per cent., is then applied to the bleeding conjunctiva by means of a pledgelet of good quality cotton-wool wound round a glass rod. If necrosis of the conjunctiva occurs, the use of escharotics should be deferred until the necrotic membrane has disappeared. Otherwise the perchloride should be applied once daily.

Improvement should have occurred at the end of a week, and at the end of a fortnight the commencement of the change into trachoma III. should be observed. At the end of a month a network of cicatricial lines should be seen. This improvement is usually permanent, although in the absence of further treatment relapse is liable to occur with a redevelopment of follicles. The treatment may be supplemented by the use of zinc sulphate drops ½ per cent., or zinc chloride drops ½ or ¼ per cent., bathing with an antiseptic solution such as perchloride of mercury, 1 in 5000, and anointing the edges of the lids with ung. hydrarg. ammon. dil. The mechanical treatment sometimes needs to be repeated after 7 or 15 days. Inevitably some cases develop entropion, seeing that the process of cure depends on the laying down of scar tissue. If inflammatory signs and excessive discharge suggest a superimposed conjunctivitis, no operative procedure should be undertaken. In such cases the conjunctivitis should first be treated with silver nitrate, 2 per cent.

Invasion of the Cornea.—When ulceration from trachomatous invasion of the cornea occurs, silver nitrate, 2 per cent., should be applied to the conjunctiva once or in severe cases twice daily.

The eye should not be tied up except out of doors, but should be bathed by the patient every ten minutes or so during his waking hours with perchloride of mercury solution 1 in 5000, or a weaker solution if the skin becomes irritated. In ordinary cases the pupil should be kept dilated

with atropine; but if a perforation seems likely to occur atropine should be discontinued.

Pannus.—Treatment of pannus is for the purpose of improving deteriorated vision, but in advanced cases scar tissue obstructs the nutrient flow between the corneal corpuscles and renders necessary the persistence of pannus vessels. I therefore believe that attempts to reduce the vascularity of the cornea in trachoma are harmful.

When there is great thickening of the tarsus together with the presence of follicles of the conjunctiva, the radical operation of combined excision of the tarsus with the overlying conjunctiva is much the best procedure, provided the conjunctiva of the fornix is free from follicles.

Trachoma II. (*b'*) may be treated by curetting and application daily of perchloride of mercury 1 per cent., or more satisfactorily by the combined excision of tarsus and conjunctiva overlying the tarsus. This operation may be performed for upper and lower lids.

Trachoma II. (*b''*) must be treated by the combined excision operation. Even after this it is common for symptoms of spring catarrh to persist.

Trachoma III.

In this stage cicatrisation has definitely begun, or is more or less advanced. Islands of inflamed conjunctiva or of trachomatous follicles are seen to be surrounded by a network of fine lines of connective tissue. In this stage spots of necrosis often result from the pressure of the shrinking connective tissue (post-trachomatous degeneration). The necrotic tissue may remain as a cyst or may become calcareous.

The beginning of this stage is best treated by the application of perchloride of mercury solution, 1 per cent., daily. This may be alternated with the use of copper sulphate solution 10 per cent. The old-fashioned copper sulphate stick is very painful, may cause excessive scarring, and when many patients are being treated carries infected mucus from one to another. In some cases which are not apparently very severe corneal complications occur in the form of small white spots of infiltration situated beneath the superficial epithelium, not staining with fluorescein. Copper should never be used in this condition; daily treatment with silver nitrate solution, 2 per cent., together with frequent skilled hot bathings, and atropine drops 1 per cent., should be substituted. In certain selected cases the combined excision of tarsus and overlying conjunctiva may be satisfactorily performed. This operation has the advantage of curing entropion and of preventing its occurrence, for entropion depends on cicatricial changes in the tarsus; when the tarsus has gone it cannot occur. When the operation is performed with ordinary skill there is never any ptosis afterwards, and from inspection it is impossible to know that any operation has been performed.

The complications of trichiasis and entropion frequently occur in this stage of trachoma. The three operations, Streatfield's, van Milligen's, and Saunders's, for relieving these conditions cannot here be described.[1]

The necrotic foci mentioned as frequently found in this stage merely require opening, and calcareous particles, if present, picking out.

Trachoma IV.—Prophylaxis of Trachoma.

Trachoma IV., being the stage of cured trachoma, requires no treatment unless a relapse occurs.

Prophylaxis.—It is impossible here to deal with the prophylaxis of trachoma from a general, social, or institutional standpoint, but a few words must be said as to prophylaxis in the family of the sufferer. If possible, the infected person should have a separate bedroom; in any case a separate bed. He should not use the same washing utensils, nor the same towel or table-napkin. Roller towels should be abolished from the house. All members of the family should have instilled into their eyes as a prophylactic drops of zinc chloride solution, ½ or ¼ per cent., twice a day. Adequate treatment for the infected person may have to be persisted with for years.

A. F. MACCALLAN, C.B.E., M.D. Camb., F.R.C.S. Eng.,
Assist. Ophth. Surg., Westminster Hospital; Asst. Surg., Royal Eye Hospital; formerly Director of the Egyptian Government Ophthalmic Hospitals.

Special Articles.

BRITISH ORTHOPÆDIC ASSOCIATION.

THE ANNUAL MEETING.

THE ninth annual meeting of this Association was held in London on Oct. 22nd and 23rd. On the morning of the 22nd the meeting took place at the house of the Royal Society of Medicine. After the short business session, Mr. H. A. T. FAIRBANK gave his presidential address on Some General Affections of the Skeleton. He showed a large number of clinical photographs and radiograms, illustrating the various points in the co-relation of certain of these obscure bone conditions.

The subject selected for discussion at the morning session was

Injuries of the Carpus.

Mr. MAX PAGE, who opened, commented on the fact that the knowledge of this complicated subject was of comparatively recent date. He quoted largely from Mouchet, Destot, and Kellogg Speed, and presented a simplified classification based on the findings of the French school. He dealt in some detail with the treatment and prognosis.

Mr. S. T. IRWIN gave a careful analysis of the records of the Royal Victoria Hospital, Belfast, during a five-year period. He reported the incidence of each particular fracture, the period of disability, and the functional end-result. Mr. H. PLATT suggested a classification, similar to that of Mr. Page, and reported in detail the results of carpal injuries from his fracture clinic at Ancoats Hospital, Manchester, over a five-year period. Mr. THURSTAN HOLLAND, Mr. R. C. ELMSLIE, and Mr. N. DUDLEY BUXTON carried on the discussion. Sir ROBERT JONES gave the results of his personal experience, and described the treatment he was accustomed to employ. He said that, with a fractured scaphoid, if the wrist moved freely under anæsthesia, he immobilised for three weeks in dorsiflexion and the end-result was good. He had found that if the wrist did not move easily under the anæsthetic prognosis was less good. He did not consider that removal of the whole or part of the scaphoid, although sometimes necessary, resulted in a perfect hand.

Clinical Meeting.

The clinical meeting on the 22nd was held at St. Thomas's Hospital. Two operations were performed, Mr. W. R. BRISTOW removing a torn cartilage from the knee-joint, and Mr. PAGE arthrodesing a hip. This was followed by a clinical demonstration; Mr. BRISTOW showed a group of patients treated in the orthopædic department of the hospital, illustrating points of interest in the surgery of the joints and bones. The first group showed the results obtained from a modified arthroplasty of the hip, the reconstruction operation devised by Whitman—viz., excision of the head, remodelling of the neck, and lowering of the trochanter. Three patients whose hips had been arthrodesed were shown for comparison. Four patients were shown to illustrate the end-results of the treatment for recurrent dislocation of the shoulder; one cured by a deltoid muscle sling, one by repair of the glenoid ligament after the Clairmont-Ehrlich operation had failed. The other two patients were cured by a bone operation to raise the rim of the glenoid fossa, the glenoid ligament being found torn and so shrivelled as to be incapable of repair. Two patients illustrated reconstruction of the elbow-joint, and one who had had a fractured internal epicondyle removed from the interior of the joint. This patient, whose elbow was stiff for some long time, had recovered full movement. Two patients in whom the ankle-joint had been arthrodesed for old mal-united Pott's fracture were shown walking well and without pain. Patients were shown illustrating the result of repair of muscle and tendon, bilateral

rupture of the ligamentum patellæ, repaired by a free fasciæ graft, and bilateral rupture of quadriceps by transplantation of tensor fasciæ femoris to patella. Cases were shown of chronic sclerosing osteomyelitis (Garré), fibrocystic disease of the neck of the femur, dealt with by curetting and grafting, hæmophiliac knee, and adolescent coxa vara treated by open operation. A group of patients with affections of the knee-joint were shown illustrating the end-results after synovectomy, cheilotomy, patello-femoral arthroplasty. Mr. PAGE showed two patients in whom he had removed five inches of bone from the femur to shorten the leg, and a patient who was cured of a clicking jaw by the removal of the inter-articular cartilage.

The members were entertained to tea in the Shepherd Memorial Hall by invitation of Miss Lloyd Still, the matron of St. Thomas's Hospital, after which a short visit was paid to the orthopædic wards. Dr. J. B. MENNELL then gave a demonstration in the massage department of the methods he employs in manipulating the joints. He explained the various points of his technique.

Short Papers.

The morning of the 23rd was devoted to short papers.

Mr. E. P. BROCKMAN reported several cases of renal rickets and showed a series of radiograms. He also showed a tibia from one of the patients and for comparison the tibia from a rachitic patient, and a normal tibia from a child of the same age. He had investigated the microscopic changes about the growth disc, and showed a series of coloured drawings illustrating the changes which he had found.

Mr. G. PERKINS reported the end-results of the operation of excision of the head of the first metatarsal in 50 patients from the orthopædic department of St. Thomas's Hospital. He found that from the patient's point of view the operation gave a good result in 96 per cent. of cases. He called attention to the fact that pain about the forefoot was not relieved by excision of the head, and that free mobility must be restored to the toes. He suggested that the bad results, associated in the mind of some surgeons with this operation, were due to coexisting pain about the forefoot and that treatment for the two conditions should be simultaneously undertaken. Mr. Perkins's paper was discussed by Prof. MURK JANSEN, Mr. T. H. OPENSHAW, Mr. A. B. MITCHELL, Mr. ELMSLIE, Mr. T. ARMOUR, Mr. BRISTOW, Mr. W. A. TRETHOWAN, Mr. ROCYN JONES, and others.

Mr. C. LAMBRINUDI described an operation which he had devised for the cure of paralytic drop-foot, and showed two patients.

Mr. BROCKMAN reported a case of femoral aneurysm arising in a boy suffering from Pott's disease of the spine. He showed the vessel which had been excised by Sir Cuthbert Wallace, and a microscopic section of the artery wall showing local tuberculous disease.

Mr. J. F. BRAILSFORD showed radiograms of the spine from the patients illustrating spondylolisthesis—erosion of the bodies caused by aneurysm and the localisation of a foreign body.

Owing to shortness of time papers by Mr. Page, Prof. Jansen, and Mr. J. B. Barnett, which were to have been presented, were taken as read.

Visit to Orthopædic Hospital at Pyrford.

On Saturday afternoon some 40 members visited St. Nicholas' and St. Martin's Orthopædic Hospital at Pyrford, in Surrey. This open-air hospital of 160 beds, which belongs to the Waifs and Strays Society, is staffed by the orthopædic department of St. Thomas's Hospital and Dr. T. M. Hardy, of Byfleet, the local physician. Members were shown round the hospital and visited the open-air wards, after which a clinical demonstration was given. A number of patients was shown, including a group of eight cases of pseudo-coxalgia with serial radiograms showing the various changes, over a three-year period, and for comparison two patients with flattening of the head of the femur and cavitation of the neck.

THE ANNUAL DINNER.

During the session of the British Orthopædic Association held last week, the dinner of the Association took place on Friday, Oct. 22nd, at the Café Royal, London. Mr. H. A. T. FAIRBANK, the President of the Association, was in the chair, and was supported by King MANOEL, of Portugal, and a group of representative guests.

"The Prosperity of the Association" was proposed by Sir JOHN BLAND-SUTTON in unexpected and amusing terms, under which lay the serious message that the public belief in osteopathy must be countered by resolute work on the part of the rising school of British orthopædic surgeons. The prospect lay before these surgeons, he said, of taking over the whole of limb surgery in proper relation to surgery in general, the era of steel and leather encasement having given way to scientific principles; and he urged that the increasing number of men attracted to orthopædics should learn the lessons of comparative anatomy in relation to the treatment and manipulation of joints from the extraordinary range and delicacy of action possessed by the lower animals, many of whom were able to scratch any part of their persons with their hind limbs, while the elephant, planted like a rock on enormous pillars, could execute tiny gentle movements. He warmly recommended to the attention of orthopædic surgeons the unhappy moral side of many of their patients, whose outlook on life was prone to be morose owing to their physical handicaps. The reward of successful treatment that the orthopædic surgeon might obtain was instanced, he said, by the gospel miracle where the cripples "went on their way rejoicing," while poets, from Homer downwards, had testified to the fact that physical failings might warp in all their social relations the mentality of the victims, Thersites being a classical example of this decadence.

The PRESIDENT, in reply, alluded to the presence of a representative group of guests and testified especially to the debt owed by orthopædic surgery to Sir Robert Jones and King Manoel, of Portugal, who throughout the war had worked untiringly in close association, their pertinacity having succeeded in instituting a general organisation of orthopædic treatment for the sufferers in the war. He thanked the authorities and staff of St. Thomas's Hospital, and the President and Council of the Royal Society of Medicine for the valuable facilities accorded to the orthopædists in session, and in acknowledging Sir John Bland-Sutton's appreciation of the growing specialty, he mentioned that it was the intention of the Association to publish a journal recording their activities.

The toast of "The Guests" was proposed in eloquent terms by Sir ROBERT JONES, and was replied to by Sir ARTHUR STANLEY, Chairman of the Joint Council of the British Red Cross Society and Order of St. John. Sir Arthur Stanley, speaking with great gaiety as one "who had for many years been encased in steel and leather," found that the implication of moroseness alluded to by Sir John Bland-Sutton might be a very convenient one in his position as treasurer of St. Thomas's Hospital, inasmuch as when demands were made upon the institution (as they might be by Mr. Rowley Bristow in behalf of his orthopædic department) inability to meet those demands would now be attributed to an unfortunate infirmity of character.

In response to the wish of the gathering, King MANOEL also replied for the guests, though, as he said, he was hardly a guest, inasmuch as he was an honorary member of the Association who had ceased

active coöperation. King Manoel made moving references to the difficulties which his "twin brother," Sir Robert Jones, and himself had been compelled to face in the early days of the war, when the establishment of an orthopædic centre at Shepherd's Bush was first decided upon. He told how the movement had spread till other centres, great and small, were established in considerable number, and pointed out that the experience thus obtained by the public, in learning what could be done, by the medical profession, and by the surgeons, in learning how to do it, was now splendidly available for sufferers from industrial accidents.

"The Health of the President" was proposed by Prof. MURK JANSEN (Leyden), when Mr. FAIRBANK, in reply, said that the detailed labour had fallen upon Mr. R. C. Elmslie, the Vice-President of the Association, and Mr. Bristow, orthopædic surgeon at St. Thomas's Hospital, where the excellently attended meeting of the day had been held. Mr. BRISTOW also replied.

At various intervals between the speeches Mr. Victor Marmont, a pianist, accompanied Mr. Tom Kinniburgh, who sang an assortment of suitable songs in a spirited and artistic manner which should make him in request at similar gatherings.

AMERICAN PUBLIC HEALTH ASSOCIATION.

FIFTY-FIFTH ANNUAL MEETING.

(FROM AN OCCASIONAL CORRESPONDENT.)

THE annual meeting of the American Public Health Association was attended by health officers and others interested in the promotion of public health from all parts of the United States, from Canada and from South America. The conference assembled at Buffalo N.Y., on Oct. 11th and lasted four days. In this time a great amount of scientific work was reported and discussed, the various sections meeting synchronously, so that it is impossible to mention in brief space the greater part of the subjects raised. The most notable trend observed, however, was an inclination to seek a new orientation in public health work; one that should mobilise the general practitioners of medicine and engage the support of all the educational forces of the country.

Presidential Address.

The note of appraisal was sounded in an eloquent opening address by the President, Prof. C.-E. A. Winslow, of Yale University, who attributed the astonishing progress of the last 50 years to three elements in the public health movement: environmental hygiene, laboratory research, and education. But he pointed out that these methods had not achieved uniform success in combating the different diseases. Comparing statistics made for Manhattan and the Bronx in 1873–75 with figures compiled for greater New York in 1923–25, he showed that mortality-rates have fallen much more for some diseases than for others (scarlet fever 99 per cent., diphtheria 95 per cent., tuberculosis 79 per cent., acute respiratory diseases 53 per cent., and all causes together 42 per cent.). Three diseases show in this period a very marked increase in mortality: cancer 176 per cent., heart diseases 187 per cent., and diseases of the arteries 650 per cent. This new situation demands new methods. The early recognition of disease and attention to personal hygiene are obvious lines of defence: a man may die at 70 because he had an infected tooth at the age of 12. Mental hygiene is destined to play a rapidly increasing rôle (perhaps some day a preponderant rôle) in the public health movement. Since early diagnosis is so important, all physicians must coöperate in discovering early signs of disease. But since the public will not pay for medical advice until actual sickness is experienced some new way of remunerating the physician must be discovered. Dr. Winslow admitted that he had once been sceptical of the value of national health insurance, but as the result of a recent visit to England under the supervision of the Ministry of Health, he had found the Act "working better than its unsympathetic critics would have thought possible five years ago." Dr. Winslow was careful not to advocate any particular scheme of social medicine, though he made good fun of those who have an unreasoning fear of an ill-defined bogy that is called "State medicine."

The Dollar Value of a Life.

In a paper on the Economics of World Health, Dr. Louis I. Dublin, of the Metropolitan Life Insurance Company, gave some arresting figures of the economic value of human life. Taking males in the $2500 per annum salary class and subtracting from their wage-earning capacity the cost of their maintenance till death, he put the present cash value of each individual at the age of 18 as $29,000. By similar calculations he makes the vital capital of the United States five times as great as its material resources. The application of our present knowledge of preventive medicine would, he believes, mean a saving of six billion dollars yearly to the United States. In the last 20 years the Metropolitan Life Insurance Company has spent 20 million dollars in the health supervision of its industrial policy-holders, reducing the mortality by 30 per cent. (double the fall in the general population) and saving the company 43 million dollars.

Death-rates of Male White Physicians.

In a study of the above rates by age and cause, Dr. Haven Emerson and Miss Harriet E. Hughes brought out the rather remarkable fact that 16·9 per cent. of the 2544 physicians who died in 1925 were reported to have died from ill-defined or undetermined causes. The death-rates from all causes among doctors in 1925 were lower than those for "all occupied males" in 1920 in the age-groups 25 to 44 years and 65 years and over, but almost identical in the age-groups 45 to 64 years. The specific death-rates for physicians from organic heart disease, pneumonia, and diabetes were found, on the whole, to be decidedly higher than that for all occupied males in the corresponding age-groups. These figures suggest that a greater emphasis on preventive medicine is necessary in the teaching of the medical schools.

A group of teachers of hygiene in colleges met for the first time at this year's conference. They were addressed by Dr. John Sundwall, of the department of public health at the University of Michigan, Dr. Thomas A. Storey, of Standford University, California, and Dr. H. G. Rowell of Columbia University, New York. The meeting was very well attended and a committee was appointed to continue the organisation of this group and to coöperate with the American Student Health Association.

A local committee provided a very attractive programme of entertainment, including a visit to Niagara Falls, where the delegates were entertained by the Shredded Wheat Biscuit Company, and subsequently saw the falls illuminated.

The new president of the Association is Dr. Charles V. Chapin, of Providence, R.I., and the meeting place for the year 1927 is to be the city of Louisville in Kentucky.

EXTENSION OF EVESHAM HOSPITAL.—The difficulties of small country hospitals are well illustrated by the attempt that is being made to obtain the means of enlarging this cottage hospital. Since 1880, its first year, the number of patients has increased eleven-fold, whereas subscriptions have increased only three-fold. The population of the district served is growing, and the medical staff are constantly troubled by the obstacles in the way of dealing with urgent cases. There are 14 beds and 2 cots, and it is proposed, as a palliative, to erect a women's ward of 12 beds and a children's ward containing 4 cots, to improve the operating theatre, and provide other necessary adjuncts.

MEDICINE AND THE LAW.

Intoxicating Liquor or Patent Medicine?

Is "Wincarnis with quinine" an intoxicating liquor or a patent medicine? The inquiry came before the courts in relation to the excise and the provisions of the Licensing Acts. The High Court seems to answer that it is both. A chemist and druggist, who in his shop at Brighton sold a policeman a bottle of Wincarnis with quinine, was the holder of an excise licence authorising the sale of patent medicines; moreover, the bottle wrapper bore the usual excise label declaring that medicine stamp duty had duly been paid on the contents. But the chemist did not also hold a justices' licence entitling him to be a retailer of intoxicating liquor. The Brighton bench held that by this omission he had committed an offence; they fined him £1 and ordered him to pay the analyst's fee. The point was reviewed by the High Court last week upon a case stated by the magistrates and the decision was upheld. The magistrates had found that the liquid was an intoxicating liquor, was medicated, and tasted of quinine. The High Court had only one question to consider—namely, whether there were materials whereon the magistrates could reach the conclusion which they in fact reached, that this liquid was wine. The court was satisfied that the magistrates had such materials; indeed, there were very scanty materials to the contrary. Before the Brighton justices a policeman had testified that he went to the chemist's shop one day in January last and asked for a bottle of Wincarnis. The chemist replied that he did not stock it and advised him to try a wine merchant. A few days later the persistent policeman was able to buy a bottle of the desired liquid at the same chemist; he found that the advertisements upon the wrapper bore statements that it was "made with choice wine," "contains one grain of quinine to the ounce to meet the requirements of the Board of Inland Revenue," "contains 28 per cent. of proof spirit," and advised that the bottle should not be shaken "as there is occasionally a little sediment from the wine after bottling." All these matters were prima facie evidence that the liquid was made with wine, and no rebutting evidence was adduced. The analysis indicated the presence of 27·99 per cent. proof spirit (equal to 13·99 per cent. of alcohol) and 1·2 gr. of quinine to the fluid ounce. The British Pharmacopœia was quoted as showing that a mixture containing one or more grains of quinine per fluid ounce was considered a medicine, and a good port wine was stated to contain 30 per cent. of proof spirit.

On the appeal it was argued for the chemist that the true test was palatability. Hosts do not circulate after dinner a decanter of "Wincarnis with quinine" in place of port; the liquid, as the magistrates said, "tasted of quinine," and quinine is bitter and unpleasant to the palate. It was answered that there are recognised beverages of which quinine is an ingredient. As the Lord Chief Justice observed, it is a question of degree. How much quinine is necessary to make wine cease to be wine? At one end of the scale a man might put a very little medicine of a pleasant taste into a very large quantity of good wine; at the other end he might put a large quantity of nasty medicine into a small quantity of indifferent wine. The magistrates in effect said that the liquid in the bottle sold at Brighton was wine, and there was no ground for upsetting their finding. Abandoning for once the traditions of judicial ignorance of the ways of the world, Lord Hewart added some shrewd remarks on the commercial aspect of the case. The commercial problem, he said, was how to put enough medicine into the wine to make it cease to be wine for the purpose of argument, and at the same time not make it unpalatable to the men, women, and children who would drink it—"especially those women who thought they suffered from nervous disorders and wanted an excuse for drinking port at 11 o'clock in the morning."

Unregistered Practitioner Convicted.

Claiming to be able to cure leprosy, diabetes, cancer, appendicitis, consumption, as well as many other minor and major ills, Emil Kumst was found guilty at Pretoria last month on 12 counts of contravening the Medical, Dental, and Pharmacy Act by practising as a doctor while unregistered. He was sentenced by the magistrate to a fine of £120 or 168 days' hard labour. Notice of appeal was given. Kumst, who had a well-advertised business for "pure natural oils" at Pretoria for some time, sold his mixture at between 17*s.* and 35*s.* a pound. According to the Government analyst, the actual cost of the mixture, which consisted of paraffin oil, eucalyptus oil, turpentine, sperm oil, and alkaline water, was about 4½*d.* a pound.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Accommodation for Encephalitis Lethargica.

SOME months ago the Scottish Board of Health held a conference to arrange some practicable method of dealing with certain types of encephalitis lethargica. The Glasgow Parish Council came forward with an offer of some 60 beds in the fine hospital at Stobhill, and their scheme is now in full operation. The method of selection of cases is this. When accommodation is wanted the medical officer of health of the area applies to the Board for a special form, which covers (1) acceptance by the local authority of responsibility for the case, and (2) a medical report with sufficient detail to enable the Board to judge whether the case is suitable for admission. In this way it is possible to make the most profitable use of the beds, and the parish council provides expert medical treatment and nursing on terms arranged. But apart from the special "local authority patients," the Council has had to provide for cases among the ordinary poor. At present the numbers in Stobhill are rapidly approaching a hundred, and there is still a long waiting-list in Glasgow, not to speak of other parts of Scotland. The cases are in charge of a visiting neurologist, who is also responsible for the mental observation wards, and the records and results of this institution are sure to be of great value in the study of a disorder that must still be regarded, pathologically and clinically, as a puzzle. The view is gaining ground that the great outburst of the disease is over and that we are now getting its late effects. The difficulty, in many cases, of determining the differential diagnosis is, of course, well known. Often the sequelæ seem to be the only proof that an alleged attack of influenza or similar symptom-group was really encephalitis, but when the true causation is discovered the facts will doubtless fall into their place. Meanwhile the disease is creating a troublesome problem, and the notifications, though small compared with those of the leading infections, are still considerable.

An Experiment by Civil Servants.

Rather more than a year ago a new society was formed called the East of Scotland Civil Service Association. It was registered as a limited company not for profit and the membership was at first restricted to 1500, but at a very early stage this limit had to be raised by another thousand. Though the members are scattered from the Orkneys to Portsmouth the vast majority of them live within 20 miles of Edinburgh. The association runs a nursing home which reflects great credit on the management. No doubt the special conditions of the Civil Service make possible many economies that might be beyond the powers of a mixed community—for example, the method of collecting annual subscriptions through the salary warrants, and the immediate availability of skilled administrators both medical and lay. But the main fact is that the nursing home has been proved to serve its purpose, which is to secure first-class surgical and

gynæcological treatment at fees within the range of the various grades of civil servants. During the year 148 members' cases, involving 122 operations, have been admitted, besides 25 non-member cases. Among member patients there were 39 operations for enlarged tonsils and adenoids and many other minor complaints were dealt with, but there were also many major operations and a number of medical cases were admitted, some for consultation. Twenty-eight X ray examinations and ten cystoscopies were made. As might have been expected, there was a deficit on the first year's working, but the revised terms will wipe this out without much difficulty. The association is to be congratulated on the success of a new and very important experiment in what is essentially a scheme of medical and surgical insurance. This type of paying hospital seems to have solved the difficulties of one large section of the community.

A Course on Heredity.

The Edinburgh School of Social Study and Training has been fortunate in securing a course of six lectures from Dr. F. A. E. Crew, director of the Animal Breeding Research Department, Edinburgh University. Some of us are old enough to have watched the transformation that Darwinism effected in biology as taught in the universities, and were therefore young enough to take quite seriously Weismann's "non-inheritance of acquired characters" and to follow the Spencer-Weismann controversy on the "all-sufficiency of natural selection." Thus we find it peculiarly stimulating to watch the young giants of the Mendelian era in their efforts to displace generalisation by the results of experiment. One of the great misfortunes in scientific history was that Mendel and Darwin did not know each other, and it is impossible even to guess what Darwin would have said about Mendel and his work. Thanks, however, to Bateson and his many brilliant successors, this generation does not lack exponents, and we welcome every attempt to make the new results an open book not to medical students only, or to the strictly scientific students, but to health visitors, nurses, and others interested in social affairs. Dr. Crew's course ought to be largely attended. He will discuss the mechanism of organic inheritance and of sex-determination, the inheritance of physical and mental characters in man, inbreeding and outcrossing, and the application of genetic facts to social and racial problems. At a moment when the problem of the feeble-minded is exciting world-wide interest it is gratifying that at least one school of social study offers a platform to the worker in pure and applied biology.

The Veterinary Services.

To judge by newspaper reports of the annual meetings of the two Scottish veterinary colleges there seems to be a good deal of feeling between East and West. What the merits of the case are I do not know, but it is certain that in recent years veterinary education has enormously improved, and it can now be fairly said that the training of veterinary officers is grounded on a well-proportioned curriculum of scientific studies. Recent developments under the Ministry of Agriculture—which still has jurisdiction in Scotland so far as animal diseases are concerned—have made a considerable number of openings for young graduates, and the Milk and Dairies Act and Tuberculosis Compensation Order have led to the appointment of a relatively large number of whole-time officers. It will be interesting to see whether the effects of the Compensation Order will include a drop in the rates of human tuberculosis of all kinds. The next ten years should provide a real test of the theories about milk infection.

Scarlet Fever.

In his bulletin for May, 1926, Dr. A. S. MacGregor, medical officer of health for Glasgow, writes: "Both scarlet fever and diphtheria are somewhat more prevalent this year; in fact, scarlet fever appears to be increasing in incidence from year to year since 1915." Certainly the incidence for September and October up to date shows a distinct increase over the corresponding months of last year, but the climax usually comes about this time, and the next week or two will show whether this is to be accounted an exceptional epidemic. The weekly scarlet fever incidence for the large towns as a whole is not yet quite so high as it was in September, 1925.

PARIS.

(FROM OUR OWN CORRESPONDENTS.)

Professional Donors of Blood.

SOME leaders of the medical profession in Bordeaux propose to set up a service of blood transfusion for the local hospitals. A report presented to the Medico-Chirurgical Society sets out the ever-present need in hospitals of professional donors, who may be adult subjects chosen from the medical personnel (internes, externes, students), from the hospital attendants, or at need from a larger public. Since donors must be easily accessible a list of them is to be permanently posted in the bureau of the hospital with a daily rota of names. The suggestion is that donors should be examined every three months by the laboratory chief, only those of group 4, so-called universal donors, being retained. Experience having shown that loss of blood to the extent of 500 c.cm. is harmless, this amount is to be asked of each donor not oftener than once a month, the donor having the right to five days' complete rest after a bleeding. For the four hospitals of Bordeaux the number of remunerated donors required is estimated at 15, a number which would be enough to ensure 10 to 20 urgency transfusions a month. Non-urgent transfusions can be arranged with voluntary donors selected from the patient's immediate circle on the ground of compatibility.

Ætiology of Abortion.

Although abortion with intent may constitute a large group in certain circles, any tendency should be avoided to exaggerate its prevalence or to include in the intentional group all abortions of unknown origin. Dr. Henri Vignes, accoucheur to the Paris hospitals, in a recent study of the ætiology of abortion, finds that syphilis constitutes a not inconsiderable group, while numerous other factors come into play. Many abortions are due to disease of the ovum or of the other products of conception. There is a pathology of the embryo and a pathology of the fœtus, and as far as present knowledge goes the cause escapes us in a considerable number. Out of 530 abortions Brion only found a well-defined cause in less than a third of the cases—namely, faulty insertion of the placenta, 62; syphilis, 52; albuminuria, 27; hydramnios, 13; uterine malformation, 7. In 367 cases the cause could not be ascertained.

Diuretic Action of Quinidine.

Quinidine, employed to regulate cardiac arrhythmia or paroxysmal tachycardia, seems to have another effect so far unrecognised—namely, a diuretic. Dr. Labbé (Paris) in administering the drug in old persons—predisposed, it is admitted, to polyuria—has found that quinidine is apt to cause troublesome diuresis, which stops when treatment is discontinued. Quinine and quinidine in febrile patients accelerate the heart's action without vaso-constriction, with a resulting increase in blood pressure, and in subjects possessing normal function an increase in excretion of urine, but Dr. Labbé's old persons were not febrile. The fact that quinidine gives rise to diuresis, although unexplained, should be noted as it may have useful application.

Glycosuria and Diathermy.

Dr. Bordier (Lyon) has reported in the *Archives d'Electricité Médicale* the case of a young man of 20, two years diabetic (9·75 g. glucose in 2500 c.cm. urine per day) in whom the glycosuria, polydipsia, and asthenia all disappeared a week after the application of diathermy by d'Arsonval's method, a current of

3200 milliampères being given for periods of half an hour repeated six times. There is reason to suppose that high-frequency oscillations may give rise to some modification in the islands of Langerhans, where the internal secretion of insulin takes place, but the result could also be explained by direct action of the current on the liver.

Health Conditions at Madagascar.

Prof. Koun, assistant director of the medical school at Antananarivo, reports that the natives of Madagascar have high fecundity, which is counteracted by high morbidity and mortality, due especially to respiratory affections, malaria, and plague, which assume great virulence. The environment is characterised by marked and sudden climatic changes and modified bacterial virulence, as well as the pathogenic effects produced by infection. The native medical organisations are too individualistic and modern methods are deplorably neglected. Penalties for violations of sanitary regulations are not enforced. Spirochætoses frequently constitute troublesome complications, and most diseases develop in the presence of pre-existing malaria.

New Theory of Anaphylactic Shock.

At a recent meeting of the Académie des Sciences, A. Lumière and J. Enselme presented the results of studies in anaphylaxis made in guinea-pigs. The authors advance the theory that anaphylactic shock is produced by irritation of nerve-endings in the vascular wall, induced by contact with flocculated particles formed when the releasing substance meets the sensitised serum of the patient. For preventing the shock the authors reason that anæsthesia of the vascular nerve-endings in question should prove effective. They have supported this deduction by experiments with allocain hydrochloride. The anæsthetic effect, however, wholly disappears in two hours.

The prefect of police has decided that the Paris milk-supply must be distributed preferentially, and first of all to retailers in the local quarters of Paris; hotels, cafés, and similar establishments are to have only secondary consideration. This step has been adopted in order to assure a sufficiency of milk to French families and regular residents of Paris. The general and municipal councils of Paris are considering with much solicitude the ever-rising price of milk and the inadequacy of the supplies provided for Paris. The problem is becoming urgent, and seems to demand limitation of the exports of butter, cheese, and similar dairy products.

The free clinics in and about Paris, closed during the past few months of the summer, are again opening for the autumn. A few post-graduate courses have already started, and for students acquainted with clinical chiefs and assistants in the various Paris hospitals the opportunities for practical clinical study are very numerous and valuable. Apart from all formal connexions with the hospital advantages, graduates and undergraduates can always find an abundance of opportunity and material at Paris, provided they speak and understand a modicum of French.

On Oct. 9th a large group of Polish surgeons arrived at Paris to attend the Thirty-fifth French Surgical Congress, and were received at the Faculté de Médecine under the auspices of the well-known Bienvenue Française.

MATERNITY AND CHILD WELFARE CENTRE AT SHEFFIELD.—Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, has laid the foundation-stone of a maternity and child welfare centre which is to be erected, at a cost of £20,000, upon a site at the rear of the Cutler's Hall. There will be a waiting-room to hold 300 persons, and a shop for the sale of such foods as the doctors order. The building is being made of concrete blocks. The attendances at the present clinic are nearly 1000 a week, and since maternity and child welfare work began in 1900 the infantile death-rate of Sheffield has been halved.

Correspondence.

"Audi alteram partem."

PEPTIC ULCER AND CANCER OF STOMACH.

To the Editor of THE LANCET.

SIR,—What is the relationship between the round ulcer of the stomach and cancer of the stomach? Too much, perhaps, has already been written about this question, but since a great many authors and very many surgeons stick to the idea that many carcinomata ventriculi develop in peptic ulcers I feel compelled to ask them to reconsider their opinion.

In approaching the question we must be sure about our known quantities. Ulcer of the stomach is a word which covers very different things. It may mean an anatomical condition—that is, just the defect in the wall of the stomach without any manifest disease. In this case the ulcer is only found post mortem. On the other hand, the term is applied to the disease of a man who vomits hyperacid masses, has epigastric tenderness, and has pain at a certain time after meals. If he dies from an intercurrent disease his gastric mucosa is, perhaps, found intact. Thirdly, a man, 35 years old, with a two years' history of gastric trouble, has signs of pyloric obstruction; the acidity is normal; X ray shows a Haudek niche, and the resection of stomach reveals a carcinoma. What happens if the term ulcer is used for three things so different? Even with carcinoma there are enough difficulties to make conclusions useless when no post-mortems are performed and when no reasonable microscopical study of the resected specimen is made. The more experienced people are, the more they realise the difficulty of deciding at operation or post-mortem whether they are handling a carcinoma, which became ulcerated, or a callous ulcer.

Since the diagnosis of the two conditions is so fallacious, it is hard to establish causal relations between them, covering years, and involving data given by the patient. The simplest way to solve the problem is, of course, just to *assert*, to *affirm*, that many ulcers become cancerous in the stomach; and this way has been more successful than any other in impressing the medical world. The evidence furnished instead of proof are the specimens of ulcerated cancers from patients with or without a long stomach history. It is more a matter of psychology than purely a medical question. We all want to know, we all feel unhappy not to know, the origin of cancer. Now people claim to have found the root of the most frequent cancerous disease, and certainly most of us like to believe them and we do so.

If it were true that many peptic ulcers become cancerous, the part of the stomach which is the preferred seat of ulcer should be the site of election for cancer also. For the stomach itself this question is not easily answered because we see too seldom the early carcinoma which alone permits exact localisation. But ulcers are very frequent in the first part of the duodenum, and are similar if not identical with gastric ulcer. Where are the cancers into which these ulcers degenerate? Carcinoma of the upper part of the duodenum is extremely rare and it would be difficult to explain this if ulcer really breeds cancer. Secondly, in spite of all statistical difficulties, it cannot be denied that the peptic ulcer is much more frequent in certain towns and countries than in others; but the statistical reports of cancer of the stomach give no parallel to this geographical distribution. They ought to do so if it is true that cancer develops from ulcer. Diagnosis and treatment of peptic ulcer have been improved by clinical work, by standardisation of diets, by X ray, and by surgery. A decrease in the frequency of gastric carcinoma might therefore have been expected, but there has been no such decrease. It would be reasonable, furthermore, to expect that

cases treated by gastro-enterostomy would later on show a higher incidence of cancer than those in which resection had been done. Yet *statistics do not show* this higher incidence.

When we find an old ulcer which microscopically also is a simple callous ulcer all around and no scirrhous cancer, and when in one edge of this ulcer a small area of adenocarcinoma is found, then we are in the presence of a cancer developing from an ulcer of the stomach. Cases like this are described beyond any doubt but their number is small, and the diagnosis is difficult. If we accept only these cases as derived from ulcer then the percentage of ulcers which become malignant is very low—much lower than the 5 per cent. which are admitted even by those who do not favour the idea that cancer develops from ulcer.

But since it is true that carcinoma may develop in an ulcer and later invade and replace the ulcer, an attempt must be made to make a diagnosis from the history. The rule is that a long history of stomach trouble in an older person points towards ulcer, while a shorter history is suspicious of malignancy. This rule is good but its importance seems to have been overrated. Many cases have been reported in which after years of gastric disease carcinoma has been found, and they are used to support the theory that ulcer creates cancer.

But what do we know about the speed of growth in the manifold types of carcinoma in the stomach? Perhaps the man was right who said "Cancer of the stomach is a tragedy of which we see only the fifth act." Not seldom is a carcinoma found at autopsy in the stomach of a patient who never had any symptom of it, and reports from good hospitals put the average of unrecognised cancers of the stomach as high as 20 per cent. Can a stomach cancer stop growing for a while and continue later on; or, at least, cannot it stop making symptoms and start again?

Anschütz and Konjetzny [1] say that a history of two years does not yet speak against carcinomatous origin, and Dr. Theodor Plaut [2] has published cases showing the long duration of symptoms due to cancer. The previous history cannot be relied on to show if there has been an ulcer or not; nor can we rely upon the acidity findings, since too many cancer cases have normal HCl for a long time, and many ulcer cases show no hyperacidity. The periodicity of pain and its relation to food ingestion have also lost a large part of their significance in ulcer diagnosis. Perhaps they are symptoms of a localised stomach lesion only, and the fact that there is a circumscribed lesion at a certain point is as active in bringing out the symptoms as the character of the lesion.

A tumour in the cerebello-pontine angle is a clinical entity, and whether it is an endothelioma or a glioma does not make much diagnostic difference. In a smaller degree the same is true in the stomach, since the different agents—the cancer, the ulcer, the unknown ætiological factors in nervous conditions—can produce very similar clinical pictures. All this means that probably many so-called ulcer cases which ended in cancer have been cancer from the beginning. We have learned that the symptoms which an ulcer causes largely depend upon the constitution of the patient, the question arises if it is not the same with the small carcinoma, whether ulcerated or not.

The real frequency of cancer of the stomach will only become known when we have a complete autopsy of every patient.

I am, Sir, yours faithfully,

ALFRED PLAUT, M.D.

New York, Sept. 19th, 1926.

SCOTLAND AND VENEREAL DISEASES.

To the Editor of THE LANCET.

SIR,—In your editorial postscript which follows Mr. Wansey Bayly's letter in THE LANCET of Oct. 9th, you state "It is open to a local authority to submit any proposals for personal prophylaxis, and, if any such proposals had been made, the Board's reply would, no doubt, have been available in a public form."

On April 26th, 1924, a joint committee of local authorities in Scotland intimated to the Board "their unanimous opinion that legislation is urgently required whereby . . . . the existing prohibition of the sale of disinfectants is removed so as to permit qualified chemists to sell *ad hoc* disinfectants in appropriate form and with suitable instructions for use." The Board's reply is not "available in public form" for the very good reason that the Board have not condescended to reply at all. To maintain a dignified silence is a comparatively easy, if cowardly, way of shirking a difficult subject. The Board have likewise failed to say Yes or No to the plea for compulsory notification and treatment of venereal diseases put forward to them in March, 1925, by a conference representing one-third of the population of Scotland.

These unpleasant facts do not in any way detract from the general value of the "Pamphlet on Venereal Diseases" recently published by the Board. They merely go to prove that the views of local authorities and the opinions of the medical member of the Board and of one of their medical officers (both definitely in favour of personal prophylaxis) are flouted by the lay majority on the Board from motives of political expediency.—I am, Sir, yours faithfully,

Glasgow, Oct. 20th, 1926. ROBERT FORGAN.

INJECTION TREATMENT OF VARICOSE VEINS.

To the Editor of THE LANCET.

SIR,—I thank you for the sympathetic reference in your annotation of Sept. 25th (p. 661) to my article on the injection treatment of varicose veins in the *Ugeskrift for Laeger*. My lecture has since appeared in English with additions in *Acta Chirurgica Scandinavica* (vol. lx., Fasc. iv.–v., p. 436). I feel sure that this treatment will be of great importance, especially as regards the sequels of the disease, chronic ulcers and eczemas. Up till now I have treated 600 cases, and for the last four months I have been using a new technique *without any complications at all*. I am proposing to deliver a lecture on these new cases in the Medical Society of Copenhagen on Nov. 2nd, which will be published shortly afterwards in the *Ugeskrift* and probably later in English in the *Acta*. I consider it of some importance, for the good results of the treatment, that my latest experiences and improvements of technique should be known by surgeons intending to use the method.

I am, Sir, yours faithfully,

Oct. 21st, 1926. V. MEISEN,
Surgeon-in-Chief to the Policlinic of Copenhagen.

ANÆSTHETICS IN UROLOGY.

To the Editor of THE LANCET.

SIR,—I admit that Dr. Speid Sinclair has cause to complain of some remarks of mine published in the Transactions of the Royal Society of Medicine. They were made in a jesting spirit at the tradition which dictates the routine use of chloroform, and were never intended for publication as they made no contribution towards the scientific work of the meeting. I confess that I am as surprised as Dr. Sinclair must have been to see them in print. The proof of my remarks was carefully revised by the Assistant Editor and myself and the small slip containing the words to which Dr. Sinclair rightly objects, and for which I make an apology, entirely escaped our notice.

I am, Sir, yours faithfully,

Oct. 23rd, 1926. FRANCIS E. SHIPWAY.

"OSTEOCLASTOMA."

To the Editor of THE LANCET.

SIR,—In regard to the annotation in THE LANCET of Oct. 16th, on malignant myeloid sarcoma, we should like to make it clear that the proposal to drop the various terms now in use for this tumour in favour of the name "osteoclastoma" is the suggestion of Prof. M. J. Stewart of Leeds, who has been using this term regularly in class and for routine reporting for some years, and suggested it to us in the first instance. The view that these growths are essentially polymorphous-celled sarcomas which differentiate on the one hand into fibroblasts, and on the other into giant cells, which are the analogues of the osteoclasts, was also originated and developed by him (THE LANCET, 1922. ii., 1106).

We are, Sir, yours faithfully,

ERNEST FINCH.
HUMPHREY H. GLEAVE.

Pathology Department, University of Sheffield, Oct. 22nd, 1926.

INTERNATIONAL SANITARY CONFERENCES.

To the Editor of THE LANCET.

SIR,—A few errors have crept into the article entitled the Twelfth International Sanitary Conference, published in your issue of Oct. 9th, and perhaps you will permit me, in the interests of accuracy, to correct them. First, the Conference just held was not the twelfth but the thirteenth in the series, as shown by the following list of such Conferences: Paris, 1851 and 1859; Constantinople, 1866; Vienna, 1874; Washington, 1881; Rome, 1885; Venice, 1892; Dresden, 1893; Paris, 1894; Venice, 1897; Paris, 1903, 1911–12, and 1926. Secondly, the Sanitary Convention of this year is not the sixth to be signed, as stated, but the ninth. The others were: Paris, 1851 and 1859; Venice, 1892; Dresden, 1893, Paris, 1894; Venice, 1897; Paris, 1903 and 1912. Thirdly, the first Conference was held in Paris in 1851, and not in 1854 as stated in the article.

I am, Sir, yours faithfully,

Ealing, W., Oct. 23rd, 1926. F. G. CLEMOW.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs. W. C. B. Smith and M. T. Male are placed on the Retd. List with rank of Surg. Capts.

Surg. Lt.-Comdr. (D.) F. Thompson is placed on Retd. List at own request.

E. E. Malone, T. B. Lynagh, and C. F. Lynch to be Surg. Lts.

ROYAL ARMY MEDICAL CORPS.

Capts. to be Majs.: T. I. Dun and O. J. O'B. O'Hanlon.

Temp. Capt. J. Grant-Johnston relinquishes his commn. and is granted the rank of Capt.

TERRITORIAL ARMY.

Maj. W. A. Valentine and Maj. E. L. D. Dewdney, having attained the age limit, are retd. and retain their rank with permission to wear the prescribed uniform.

ROYAL AIR FORCE.

Flight Lt. H. McW. Daniel is promoted to the rank of Squadron Leader.

Flying Officer A. Harvey is promoted to the rank of Flight Lt.

INDIAN MEDICAL SERVICES.

Lt.-Col. H. P. Cook, on return from leave, has been posted as Civil Surgeon, Fyzabad. Dr. Badri Datt Punde has been posted as Civil Surgeon, Mainpuri. Dr. Ram Charan Lal has been posted to Bareilly. The following postings in the Provincial Medical Service have taken place: Dr. Prahlad Narain Mathur to Dehra Dun from Fyzabad. Dr. Brij Ratan Jain from Nagina, Bijnor, to Sultanpur. Dr. Kashi Prasad Bhatnagar from Chamoli, Garhwal, to Hardoi. Dr. Chiranji Lal from Lalitpur to Hamirpur. Dr. Narain Das Banerji from Dehra Dun to Bahraich. Dr. Jagdish Narain Gupta from Bahraich to Lucknow. Dr. Rasik Behari Lal from Hardoi to Mirzapur. Dr. Rameshwar Singh from Mirzapur to Muttra.

Dr. P. N. Chatterji, district medical officer of health, Moradabad, officiates as Assistant Malaria Officer, United Provinces. Col. C. J. O'Gorman, D.S.O., officiating D.D.M.S., Eastern Command, has left India pending retirement. The appointment of Maj. Seymore Sewell as Director of the Zoological Survey has been confirmed. Maj. N. D. Puri has been transferred permanently to the Punjab for employment in the Jail Department.

DEATHS IN THE SERVICES.

The death of Maj.-Gen. Sir Charles S. Ryan is announced in a telegram to the *Times*. He was a passenger in the *Otranto* from England, and died while the ship was berthing at Adelaide on Oct. 23rd. Sir Charles Snodgrass Ryan was born in Melbourne in 1853 and was first educated at Melbourne Grammar School. He qualified with the M.B., C.M. Edin. in 1875, and continued his medical studies in Paris and Vienna. In 1876–78 he served in the Turkish Army as surgeon throughout the Turko-Serbian war and the Russo-Turkish war, including the sieges of Plevna and Erzerum, and was the only Englishman to go through the siege of Plevna on the Turkish side (Order of the Medjidieh and Osmanieh). He had held the posts of senior surgeon to the Melbourne Hospital and lecturer on clinical surgery and examiner in surgery at the University of that city, while he was honorary physician to the Governor-General of Australia. During the Great War he was A.D.M.S., 1st Australian Division, at Anzac, France, and England, and was afterwards consulting surgeon to the Australian Imperial Force. In 1922 he revisited the scenes of his student days at Bonn and brought back an interesting account of German prosperity in the Rhineland, which was published in the *Times* of May 29th, 1922. He married, in 1883, Alice, daughter of the Hon. Theophilus Summer, of Victoria, who predeceased him in 1923.

Obituary.

CHARLES CLEMENT LAPAGE, M.D. CAMB., M.R.C.S. ENG.

Dr. C. C. Lapage, who died on Oct. 14th at Dolywern, near Chirk, at the age of 75, had retired from practice some years ago and had gone to live at Manchester with his son, Dr. Paget Lapage. He was educated at Leeds Grammar School and was a scholar of Magdalene College, Cambridge, where he read mathematics before taking up medical work. On going down from the University he returned to Leeds, and after qualifying in 1876 was appointed house surgeon at the Leeds General Infirmary. On going to live at Nantwich he built up a large practice and acted as consulting physician to the Brine Baths Hotel. He was also medical officer to the Voluntary Aid Detachment's Hospital, and became well known throughout South Cheshire as an examiner and lecturer in St. John's Ambulance work. In his university days Dr. Lapage was prominent in many forms of sport and he continued their pursuit as far as possible during his 42 years at Nantwich. He was well known in the hunting field. He was a widower, and leaves a daughter and five sons, two of whom are medical men.

WILLIAM GEORGE MARTIN.

THE death occurred on Tuesday, Oct. 19th, at the age of 75, of Mr. William George Martin, nearly 40 years associated with THE LANCET and for 25 years the head printer. He retired in 1915, and on the occasion a presentation was made to him by his colleagues at a farewell dinner, which was attended by the Editor and Assistant Editor, many old members of the staff, the head of THE LANCET Laboratory, and the chairman of the Company. To a large number of the older contributors of THE LANCET Mr. Martin was personally known, and it was not unusual for some of them to make their corrections and emendations under his eye, while for several years after his retirement, until failing health prevented him, he prepared the index of the paper. We have lost in him an old and valued friend.

Medical News.

UNIVERSITY OF OXFORD.—At a congregation held on Oct. 21st the degree of Bachelor of Medicine was conferred on W. H. Hudson and E. L. Fothergill.

Radcliffe Prize.—The next award for the Radcliffe Prize will be made in March, 1927. This prize of £50 is awarded by the Master and Fellows of University College every second year for research in any branch of medical science. It is open to all graduates of the University who have proceeded, or are proceeding, to a medical degree in the University. Candidates must not have exceeded 12 years from the date of passing the last examination for the degree of Bachelor of Arts, and must not, at the date of application, be Fellows on the Radcliffe Foundation. Candidates must send in their memoirs to the Secretary of Faculties, at the University Registry, on or before Dec. 1st, 1926. The award will be made in March, 1927.

UNIVERSITY OF CAMBRIDGE.—At examinations held recently the following candidates were successful:—

DIPLOMAS IN PUBLIC HEALTH AND HYGIENE.

James L. Dunlop (distinguished in Part II.), Bandi Ethirajulu, Neil E. Goldsworthy (distinguished in Part I.), Riad Abdel Noor Henein, Farid Hilmy, Bertha H. Lawler, Wasfy Omar, Harold B. Porteous, Trilok Chand Puri, John S. Smith, Margaret A. C. Symon, and Abdul Wahid el Wakil (distinguished in Part II.).

UNIVERSITY OF EDINBURGH.—At a graduation ceremonial held on Oct. 23rd the following degrees and diplomas were conferred:—

M.B., Ch.B.—Arthur Ian Barron, Oswald Dennis Beetham, Henry Caplan, Christopher William Clayson (in absentiâ), Basil George Tonge Elmes, William Andrew Erskine, Alexander Thomas Forbes, William Graham Hardie, James Donald Horsburgh, Walter Dalgleish Jackson, James M'Lauchlan Johnston, James Johnston Mason, David Olumide Peters, George Phillips, Edwin Moody Robertson, Percy Mitchell Scott, Philip Seager, Edward Morton Sewell, and Hugh Somerville.

D.P.H.—Frank Allardice, James Currie Baxter Craig, Andrew Isaac Messer, John Barré de Winton Molony (in absentiâ), Archibald Colin Murray (in absentiâ), Agnes Frances Turner.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on Oct. 20th Dr. Arthur Logan Turner was re-elected President for the ensuing year, Sir David Wallace, Vice-President, and Mr. Alexander Miles Secretary and Treasurer.—The following 36 successful candidates, out of 83 entered, who passed the requisite examinations between July 12th and 19th were admitted Fellows:—

Arthur W. Allum, Robert Armstrong, William E. Barnie-Adshead, Kashinath Dattatraya Bhave, George S. A. Bishop, Alexander Callam, Richard E. D. Cargill, Joseph R. Cornish, Douglas R. Cramb, Alexander Gillies, Keith H. Gillison, William T. Graham, Richard J. B. Hall, Harold A. H. Harris, Coimbatore Venkataramana Krishnaswami, George E. Larks, Eugene G. Lynch, Charles S. Macdougall, William B. McKelvie, Joseph A. Maxwell, Brooke Moore, Horace W. Nash, Reuben W. Payne, John H. Pilkey, John L. R. Plimmer, Walter J. Robertson, Pieter Roux, James Scott, Thomas Sprunt, John P. Stewart, Soo Hock Tan, Patrick A. Treahy, Ivan A. Tumarkin, John R. Wells, Thomas A. Weston, and Lincoln M. Zinck.

UNIVERSITY OF GLASGOW.—The following medical degrees were conferred on Oct. 18th:—

M.D.—Ian Murray (with high commendation), Andrew Davidson, Peter R. M'Naught, and Patrick J. O'Hare.

M.B., Ch.B.—With honours: Herbert H. Pinkerton, George Armour, and Robert B. Smith. With commendation: John Black, Alexander B. Smith, David F. Anderson, Donald Chisholm, Charles E. B. Lynch, and William G. MacKay. Ordinary Degree: William Allan, James C. Baird, Percy M. I. Baird, Richard R. Barr, Harold Barton, James Binnie, Alexander M. Brown, David W. Buchanan, William A. Burnett, John Burns, Robert A. Campbell, David D. Clarke, Martha Cleland, William Clement, Edward A. M'Millan Connal, Archibald Cumming, David M. Cunningham, Jackson C. Cuthbert, Joseph Dunn, Alfred Esterman, Alexander C. Ewing, Jessie A. Flett, Dorothy M. Forsyth, George Gemmill, Charles Gilmour, Margaret A. Glass, Max Gorfinkel, Mary G. Gorrie, Charlotte A. Gunson, John Hzmilton, John A. Kemp, Hugh R. Kidd, James E. W. Lee, David P. Leiper, Simon R. Lipchinsky, Robert Logan, Samuel Lurie, Donald MacCullum, Robert H. B. M'Crae, Mary L. M'Gregor, Murdoch MacGregor, Colin C. M'Kenzie, William G. MacLean, Thomas H. M'Owat, Mungo Manderson, Joseph Margolves, Alexander G. Mearns, Isabella A. Milne, Louis Morrison, George M. Muirhead, James G. Murdoch, Moses Naftalin, John O'Hara, Ian M. Orr, William T. Rankin, Duncan M. Reid, Gilbert Rorison, John P. Semple, Gavin Shearer, Andrew Shepherd, Josephine W. Shepherd, George S. Sinclair, James L. Smith, Walter C. Smith, Eliza M. K. Stevenson, Murdoch G. Tallach, George R. Taylor, Andrew Thomson, Margaret T. Tindal, Henry Vost, Laurence A. Watson, William Wilson, John Wyllie, and Hamilton B. Young.

Herbert H. Pinkerton gains the Brunton Memorial Prize awarded to the most distinguished graduate in medicine of the year 1926; and Stuart I. A. Laidlaw gains the West of Scotland R.A.M.C. Memorial Prize awarded to the candidate with the highest aggregate marks in the final examinations for the degrees of M.B. and Ch.B. held during 1926.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates have passed the Triple Qualification Examination:—

FINAL EXAMINATION.

William G. H. Allen, Oswald D. Beetham, Paul R. C. Peterson, Norman M. Eadie, Arthur G. Farquharson, Armitage E. F. L. Forbes, Wilfred L. G. Jewitt, Samuel A. B. Hosang, John A. Mains, Thomas A. P. Wynter, David Zimmerman, James G. Currie, Kudyar Marimuthu Rama Swami, Gerald M. Fox, Robert D. Kerr, James V. O'K. Murphy, Bodiyabaduge William Perera, Canagasaby Gurusamy, Henry B. Martin, Don B. J. de Silva, Horace S. Kent, Raynhild B. Werden, Myer B. Stungo, Bartlet S. Ellis, James Hendry, Alexander S. Pool, Jose Joaquim Sant' Ana Furtado e Souza, Charles H. A. S. B. Panlickpulle, Soundranayagam W. Charles, and Arleigh W. Scott.

Medicine.—Daniel J. McKenna, Ronald A. Paton, Donald Ross, Edward P. Kelly, Sarukkali Patabendige Bandulasena Gunawardena, Bennet A. van der Gert, Samson Amarasiri Gunawardana, Eric A. Y. MacKeown, and Patrick J. Bourke.

Surgery.—Adam S. Gordon, John G. Buchanan, Aly Kouchouk, Siva Ratnam Carthegasam, and Alexander R. Cowan.

Midwifery.—John D. Cooper, Don Francis Jayamaha, Kanakkumar Dhar, Ronald A. Paton, Samuel Caller, Donald Ross, Abram B. Gilston, Lucy W. MacDougall, Elizabeth Bell, Bennet A. van der Gert, Samson Amarasiri Gunawardana, Aly Kouchouk, Hector T. J. Abeyesundere, Lamahewage Martin de Silva, Patrick J. Bourke, Siva Ratnam Carthegasam, John E. Mulholland, Kanailal Palit, and Alexander R. Cowan.

Medical Jurisprudence.—Henry C. Duncan, Don Francis Jayamaha, Alexander Lipschitz, Jamieson T. F. Pearse, Walter Campbell, Matthew Clayton-Mitchell, William Ainslie, Clarence E. Vaz, Samuel Caller, Robert R. MacGibbon, Mary E. J. Magee, and Lionel M. Green.

Public Health.—Jessie G. Service, George J. Bastible, Coenraad L. Pieters, Robert Cruickshank, Flora MacDonald, Ralph S. Begbie, Alexander Lundie, Reuben Levinson, Alexandra M. MacCormick, and Ruth M. Allison.

Part I.—George M. Millar, Lillias E. B. Buchanan, John W. Starkey, Charles K. Robertson, Jean R. Mason, Philomena R. Whitaker, and John Douglas.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on Oct. 20th Mr. Percy Stocks, M.D., D.P.H. Camb., M.B. Manch., was appointed as from August 1st last to the University Readership in Medical Statistics tenable at University College. Dr. Stocks took first place in the natural science tripos at Cambridge in 1909, and in 1911 obtained a medical scholarship at the University of Manchester. He served during the late war as regimental officer in the Royal Army Medical Corps (1915–16) and bacteriologist in research laboratories (1917–18). From 1918 to 1920 he was acting school medical officer for the Bristol Education Committee and was later appointed senior assistant school medical officer. Since 1921 he has been medical officer to Galton Laboratory, and since 1924 lecturer in vital statistics and epidemiology at University College.—The Senate passed a resolution recording its high appreciation of the work of Sir Cooper Perry as principal officer of the University and giving its cordial thanks to him for his conspicuous services.

University College Hospital.—Three lectures on the History of Medicine will be delivered at University College Hospital Medical School by Dr. Charles Singer on Fridays, Nov. 5th, 12th, and 26th, at 4.15 P.M. The subjects will be: (1) The History of Scarlet Fever, (2) The Sweating Sickness, and (3) Some Points in the History of Hygiene.

HARVEIAN SOCIETY OF LONDON.—An ordinary meeting of this society will be held at 11, Chandos-street, W. 1, on Thursday, Nov. 4th, at 8.30 P.M., when a discussion on the Management of Labour with Contracted Pelvis will be opened by Mr. Aleck Bourne, followed by Mr. Eardley Holland, Mr. Clifford White, and others.

All neurologists, psychiatrists, and other medical men interested in the subject, and also senior medical students, are cordially invited to be present.

THE LATE DR. C. T. GIBBONS.—The death is announced of Dr. Charles Telford Gibbons, of Kentish Town, London. He died at his surgery on Oct. 15th whilst attending to a patient. Dr. Gibbons, who was a student of the London Hospital and took the conjoint diploma in 1897, was 58 years of age, and had worked in Kentish Town for 30 years.

A Medical Prayer Union meeting will be held, by invitation of Dame Mary Scharlieb, at 71, Harley-street, London, W., on Friday, Nov. 5th, at 5.30 P.M., when an address will be given by the Rev. Hubert L. Simpson, on the Doctor and Religion. An intimation of intention to be present will be welcomed by the hon. secretary, Dr. Tom Jays, Livingstone College, Leyton, E. 10.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Thursday, Nov. 4th, at 5 P.M., at the Medical Society, Mr. C. Max Page will continue the series of lectures on "Surgical and Medical Emergencies" by speaking on "Observations on the Treatment of Fractures." These lectures are free to all members of the medical profession. On the same day at 1 P.M., Mr. M. L. Hepburn will give a demonstration in clinical ophthalmology at the Royal London Ophthalmic Hospital. At the Royal National Orthopædic Hospital on Nov. 1st Mr. E. Laming Evans will give a special afternoon demonstration starting at 3 P.M. Both these clinical demonstrations are free to all members of the medical profession. On Monday, Nov. 1st, a Practitioners' Course in general medicine and surgery will start at the Hampstead General Hospital. The daily sessions will take place from 4.30 to 6 P.M., and the course will last for two weeks. A clinical demonstration will be given for the first three-quarters of an hour, followed by a lecture. On the same day a course in venereal diseases will begin at the London Lock Hospital. There will be clinical work each day at the hospital from 1 P.M. onwards, and four or five lectures will be given weekly during the four weeks of the course. The following courses will also be held during November: at the Royal Waterloo Hospital for Children and Women a course in medicine, surgery, and gynæcology will start on Nov. 15th, lasting for three weeks and occupying every afternoon and some mornings; at the St. John's Hospital for Diseases of the Skin from Nov. 15th to Dec. 11th, including daily instruction in the out-patient department, and lectures on Tuesdays and Thursdays; at the West End Hospital for Nervous Diseases from Nov. 22nd to Dec. 18th, consisting of lecture-demonstrations daily at 5 P.M.; at St. Mark's Hospital from Nov. 22nd to 27th, including operations, demonstrations and lectures; and at the London Temperance Hospital from Nov. 29th to Dec. 11th, when the course will be in medicine and surgery, taking place in the late afternoons. Copies of all syllabuses, of the general course programme, and of the *Post-Graduate Medical Journal* may be had from the secretary of the Fellowship, at 1, Wimpole-street, London, W. 1.

BRITISH SOCIAL HYGIENE COUNCIL.—The Council has arranged a special course of lectures to teachers and those concerned with education, which is to be held at the lecture theatre of the College of Nursing, Henrietta-street, Cavendish-square, London, W. Mr. D. Ward Cutler, chief protozoologist at the Rothamsted Experimental Station, will open the course on Nov. 4th, at 5.30 P.M., with a lecture on the Contribution of Biology to Social Hygiene. On Nov. 11th Dr. W. M. Feldman will discuss the Contribution of Physiology to Social Hygiene; on Nov. 18th Dr. J. A. Hadfield will speak on the Contribution of Psychology to Social Hygiene; on Nov. 25th Dr. Mary Buchan Douie will give an address on the Adolescent and Social Hygiene, from the Standpoint of the Home; and on Dec. 2nd the course will end with a lecture by Prof. Winifred Cullis on the Adolescent and Social Hygiene from the Standpoint of the School. Free tickets may be had from the London Secretary, British Social Hygiene Council, Carteret House, Carteret-street, S.W. 1.

HOSPITAL AMALGAMATION IN BIRMINGHAM.—The Birmingham Hospital Council has approved a scheme to provide a new hospital centre, to which we refer on page 916. The centre will be under the control of the amalgamated boards of the General and the Queen's Hospitals, on a site adjoining the University, at Edgbaston, and will have a minimum of 750 beds. At present the General Hospital has 372 and the Queen's 224 beds, and the demand for further accommodation is already urgent. The population of Birmingham itself is practically 1,000,000, and within a radius of 30 miles there are 2,000,000 more people from whom there are heavy demands. The present deficiency of beds, taking the city alone, is between 600 and 800 for general medical and surgical cases, and it is calculated that by 1931 2400 beds will be required; the present total is 1800. The provision for out-patients is equally inadequate. The joint committee point out that the presence of the Medical Faculty of the University at the hospital centre would be highly advantageous, and that if the new hospital were not a teaching centre organically connected with the medical staff of the University it would not attain rank as a first-rate hospital It is hoped that the other Birmingham hospitals will eventually coöperate with the scheme.

ROYAL VICTORIA HOSPITAL, BELFAST. — On Wednesday in last week the Duke of Abercorn, Governor of Northern Ireland, opened the new extensions, which have cost £130,000. Every department has been improved or enlarged and the number of beds has been increased by 80 to a total of 436—152 medical, 202 surgical, and 49 for diseases of women; the remainder are reserved for special cases. There are now eight operating theatres, all the beds are provided with a special wheel to facilitate movement, and a large proportion are especially suitable for abdominal cases. The out-patient department comprises a new surgical clinical theatre and a new medical clinical theatre, each with dressing rooms, and new provision for the X ray department. An entire floor is given up to a very complete dental department with 18 chairs for conservation work, separate rooms for extractions, and recovery rooms in connexion with general anæsthesia. Much space is devoted to the manufacture of dentures, and there is a complete X ray installation for dental work only. This department forms the clinical portion of the recently established Dental School of Queen's University, Belfast. Another floor has been adapted as a clinic for eye, ear and throat diseases. At the opening ceremony Dr. J. A. Lindsay, professor of the theory and practice of medicine in Queen's University, who is chairman of the hospital, declared his conviction that the voluntary system is the most economical and efficient, and the best for the patient, the doctor, and the public.

THE STATUS OF VOLUNTARY HOSPITALS.—Speaking at the Coventry and Warwickshire Hospital last week the Minister of Health said that he had never believed that voluntary hospitals were bound, sooner or later, to be superseded by State- or rate-aided institutions. The public health could not, however, be treated in water-tight compartments, and it seemed to him that the time had nearly come to consider how the voluntary hospitals might be fitted into some scheme covering a wider field than had hitherto been formulated. These hospitals already received grants for certain purposes; was it not possible that coöperation of that kind might be extended? Could we not visualise a time when those responsible for the conduct of voluntary hospitals might be represented upon some central health authority upon which would rest the responsibility of the general hospital policy for the area? Might we not imagine that in return for a certain subordination of their complete and absolute freedom to do what they liked the voluntary hospitals might receive some further assistance than that which they got at present, and could we not imagine that under a system of that kind this central authority upon which the voluntary hospitals would be represented might, while laying down in the broadest possible outline the principles upon which questions like (let him say) extension or treatment should proceed, nevertheless should leave to each individual unit the widest possible freedom in the administration and conduct of its work? At the same time he assured his hearers that he had no legislation in his mind that need cause a moment's uneasiness to the voluntary hospitals.

TUBERCULOSIS CONFERENCE.—What is called a Tuberculosis Week-end has been arranged jointly by the Tuberculosis Society and the Society of Superintendents of Tuberculosis Institutions, and is to be held at the house of the Royal Society of Medicine, 1, Wimpole-street, London, W. from Nov. 19th to 22nd. On Nov. 19th, at 5 P.M., Dr. O. Strandberg, of the Finsen Institute, Copenhagen, will read a paper on the Treatment of Tuberculosis and particularly Tuberculosis of the Larynx by Heliotherapy and Artificial Sunlight. A discussion will follow. On the next day tours have been arranged to the King Edward VII. Sanatorium, Midhurst, and the King George V. Sanatorium, Milford, or to the Heatherwood Hospital for Surgical Tuberculosis, Ascot, and the Brompton Hospital Sanatorium, Frimley. Dr. L. S. Burrell will demonstrate cases at the Brompton Hospital on Monday morning and a lunch to the foreign guests will follow. At 3 P.M. Dr. P. F. Armand-Delille, of Paris, will speak on the Diagnosis of Bronchiectasis and Lung Cavities by Intratracheal Injections of Lipiodol, and there will be a discussion. The proceedings will close with a meeting at 5 P.M., when Dr. Georg Schröder, medical director of the New Schömberg Sanatorium Wurtemburg, will read a paper on Specific Stimulant Therapy and Protective Inoculation Measures. Visitors interested in these discussions and tours are invited to attend. Application may be made to Dr. F. J. C Blackmore, Tuberculosis Dispensary, Maxey-road, Plumstead, S.E. 18.

RHEUMATISM IN INDUSTRY.—A meeting of the Citizens' Council of the Federation of Medical and Allied Services was held in London on Oct. 26th, when a number of business men and doctors met to discuss the treatment of rheumatism in industry. Mr. Spedan Lewis took the chair and an address was given by Sir Thomas Horder who described in simple terms the principal features of rheumatic disease. The nutritional factor in the ætiology, he believed was generally underestimated, whilst too much stress was laid upon exposure. Cold was not so much important a damp cold. As preventive measures he suggested the maintenance of fairly dry atmosphere, ventilation, exercise and elimination of strain. Dr. Howard Mummery, medical officer to Messrs. Lyons, said that damp must be avoided in workrooms; it was often caused by washing floors. S also must chilling of the feet and lack of sunlight and ventilation, whilst employees should have suitable storing and drying rooms for their damp out-door clothes. Dental sepsis was of enormous importance and a clean mouth should be a condition of permanent employment. The treatment of rheumatic joints was still most unsatisfactory even i London. Lumbago and neuritis, he thought, were very amenable to treatment at factories by massage and electricity These were not available in panel practice and could l had at hospitals only with great loss of time to the worke After installing such treatment at factories he had found that cases no longer remained away from work for one two weeks—when they often claimed compensation fo alleged strain—but the patients were cured by two three brief applications whilst continuing their trad The treatment of rheumatic joints, however, could not l dealt with by single firms; coöperative effort was needed He hoped that an attempt would be made by several firms to found clinics for dealing with this type of chronic rheumatism. The cost would not be prohibitive and he suggested that a committee composed of business men and doctors should look into the question. Sir Thomas Neill said that the principle involved might land the manufacturer in providing treatment for all sorts of diseases. What was needed was information such as Sir Thomas Horder has given; it should be carried into places where people lived and worked. Mr. West advocated a contribution of a penny the pound by workmen—an equal sum being given by the employers. This would go towards the cost of hospital spa treatment. In his own industry, if 20 per cent. of coal miners asked for drying rooms and baths, owners would obliged to put them in, but the miners did not want such facilities. Dr. Saxby Willis, speaking as medical officer a large firm, said that the most valuable agent in preventing rheumatism was routine examination of everyone applying for employment, and especially examination of teeth and tonsils. Service should only be temporary till septic foci had been removed, for it was easier to apply the necessary coercion before the workers were accepted than afterwards. Treatment was of secondary importance. Emphasis was laid by Mr. Morris Salmon on the financial profit resulting from the establishment of medical clinics at factories. It was decided that a committee, as suggested by Dr. Mummery, should be formed to go into the question of clinics for arthritis.

DIPHTHERIA AT MARKET DRAYTON.—The isolation ıospital being full with patients suffering from diphtheria n this village, the Lyon Memorial Hall at Hodnet, Shropshire, s being adopted to receive infectious cases from the district.

MANCHESTER'S CIVIC WEEK.—The metallic badges or medals sold in the streets during Civic Week were bought by nearly a quarter of a million people. The sum thereby ealised was £2500, which will be given in aid of the nedical hospitals in Manchester and Salford.

LADIES' MEDICAL GOLFING SOCIETY.—The autumn neeting was held at Walton Health Golf Club on Oct. 26th, he members of the society being the guests of Lord Riddell. There were over 60 entrants for the various competitions, he results being as follows: Captain's Prize for net aggre-ate, spring and autumn meetings: Mrs. Lewis Smith. Best scratch score: Miss Edith Leitch (88). Senior Division: st: Mrs. Lewis Smith; 2nd, Lady Rigby. Second Division: st, Mrs. Jennings; 2nd, Mrs. de Paula. Third Division: st, Mrs. Gordon Holmes; 2nd, Mrs. B. Marshall. Eclectic f partners: Dr. Joan Ross and Mrs. Johnson. Greensomes: st, Mrs. R. Paton and Mrs. Nicholson; 2nd, Mrs. C. Fuller nd Mrs. de Paula.

NEEDS OF THE UNIVERSITY OF LIVERPOOL.—Lord Derby, as Chancellor of the University, made a statement n Oct. 19th to representatives of nearly twenty munici-alities and urban districts in Lancashire and Cheshire on he claims of the University for increased support from the ocal authorities of the area, with a view to developing some greed scheme of financial assistance from each town ending students to the University, possibly by a small harge on the rates. In the six years immediately following he war the annual expenditure of the University greatly xceeded the income, and there was a deficit of £63,000. An additional income of at least £10,000 a year, said Lord Derby, was needed if the University was to be kept up to ate. As compared with the last pre-war year, the number f students had nearly doubled and the cost per student ad risen by 50 per cent. At the close of the proceedings he Lord Mayor gave £1000 to the University funds.

LONDON HOSPITAL DINNER.—More than 200 old tudents, including Sir Neville Howse, V.C., Minister of Health for the Commonwealth of Australia, attended the nnual dinner held at the Trocadero Restaurant on Oct. 21st. There was no musical entertainment—except a little accidental nging from the residents' table—and there were only two peeches; these, however, were so good as to please both erious and light-minded elements in the audience. Recent vents at the hospital were dealt with by the chairman, Mr. Russell Andrews, who referred to the death of Queen lexandra—succeeded as President of the hospital by Queen Mary—and spoke of changes in the medical and nursing staff. Mr. Sherren, he said, had found that he must go down to the ast again, though this time in a steamship, and the hospital ad also lost the valued services of two anæsthetists, Dr. robyn Williams and Dr. Clapham. The retirement of ster Victor, recently Sister Marie Celeste, was a further isfortune that would be felt by generations of housemen and urses whom she had taught, and by the countless patients ho thought so much of her. Amongst new appointments ere those of Mr. Victor Lack and Mr. Alan Perry, and ıe hospital was fortunate in having their services. After eading a long list of present students whose fathers and ncles had been there before them, Dr. Andrews turned from ıe present to the past and produced, as from the widow's ruse, a fresh set of stories—mostly told against himself ıd as amusing as they were characteristic. On one occasion e said, the progress of a long hysterectomy had been atched most earnestly by a certain clerk. Towards the ıd of it Dr. Andrews noticed that the bladder was beginning fill up, and, being pleased to see by this that the patient as bearing the shock of operation well, he turned to this erk and said: "Well, Mr. So-and-so, I think (don't you) ıat the bladder is increasing in size? Are you *pleased* to e that happening?" "Oh, yes, Sir, I am very pleased." Why are you so pleased, Mr. So-and-so?" "Well, Sir, shows, at any rate, that you haven't tied both ureters." his and other stories recalled the local colour, so to speak, Dr. Andrews' celebrated matinées, and everyone was ad to have a further series of reminiscences from Dr. ıul Saint, who proposed the chairman's health in an nusing and sincere speech. Whilst greatly regretting his cent retirement, Dr. Saint hoped that Dr. Andrews would ng keep up his connexion with the hospital. He was a ıssical example of a man who got on with the job, and s old students would always have the happiest memories his classes and his help. The toast was then received with thusiasm and drunk with musical honours. After Dr. ndrews had briefly replied, he proposed the health of e dinner secretaries, Mr. E. C. Lindsay and Mr. G. E. eligan, which was dealt with in the same way. The party en gradually broke up in good order.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

EMERGENCY REGULATIONS.

PARLIAMENT reassembled on Monday, Oct. 25th, for the purpose of renewing the regulations under the Emergency Powers Act in connexion with the stoppage in the mining industry.

HOUSE OF COMMONS.

MONDAY, OCT. 25TH.

A Question of Privilege: Dr. Salter's Charge against Members.

Sir A. HOLBROOK called attention to a statement made by the hon. Member for West Bermondsey (Dr. Salter) at a meeting of the Good Templars on Oct. 12th. The hon. Member then stated "I have seen many Members drunk in the House of Commons and I am sorry to say no party is exempt." When interviewed later he had said the allegation which he had made was quite true and that it was considerably on the Conservative side because there were more of them." He (Sir A. Holbrook) considered this a most outrageous attack on the dignity of the House. It was quite unjustified, and he considered that it brought the hon. Member who made it within the rules of the House as regarded a breach of privilege. Surely a statement of this character was calculated to do irreparable damage to that honourable House, and those who were there to maintain the dignity of their position. He knew that some Members on the opposite benches who came from the north of the Tweed had made it their boast that they intended to destroy the character of the House of Commons.

The Speaker said that if the hon. member intended to raise a question of privilege he must not introduce extraneous matters.

Mr. CLYNES asked whether it was permissible for an hon. Member to proceed with a statement of this kind in the absence of the hon. Member affected, and whether notice of the matter had been given.

Sir A. HOLBROOK said he sent a telegram to the hon. Member telling him he was bringing up the matter that day. Continuing, he said that Dr. Salter, when asked whether he meant the allegation, said "Bless my soul, of course I did. Obviously I am not going to name colleagues of mine but if I am challenged in the House I will tell them to their faces." He (Sir A. Holbrook) thought that was a great reflection upon the character of the Members of the House. Three or four years ago when Mr. John made a similar statement he withdrew it and made an ample apology to the House. Dr. Salter had declined to withdraw his statement, and, moreover, had repeated it on more than one occasion. That constituted a breach of privilege and he therefore moved "that the speech of the hon. Member for West Bermondsey (Dr. Salter) reported in the *Daily Express* of Oct. 13th is a gross libel upon the Members of the House and a gross breach of its privileges."

The SPEAKER, after putting the question, asked if Dr. Salter was present.

There were cries from the Labour benches of "He has not received any notice."

Mr. CLYNES said he did not associate himself with the observations made outside the House by Dr. Salter. He trusted, however, that this motion would be resisted because of the offensive terms in which the subject had been discussed and because of the unnecessary and unfair counter-charges which had been made.

An hon. Member: By a brewer's advocate.

Sir A. HOLBROOK rose to a point of order. He said that he had been charged with being a brewer's advocate.

Mr. BECKETT: Everyone knows it.

Viscountess ASTOR: Hear, hear.

The SPEAKER said that hon. Members must not make interruptions of that kind.

Mr. CLYNES, continuing, said that a speech like that of Sir A. Holbrook ought not to be made except in the presence of the Member concerned, and the House was entitled to know when the telegram was sent to the hon. Member, who was absent.

Mr. CHURCHILL (Chancellor of the Exchequer) said that the speech to which Sir A. Holbrook had drawn attention was unquestionably a very serious matter and a reflection upon the character and dignity of the House, and one which, if it were allowed to persist without being repudiated by the House, might gravely injure in the country the reputation of a democratic institution. It was always contrary to the general sense of the House to proceed to judge any matter in the absence of a fellow Member until they were assured that

the absence was due to some cause that the hon. Member had under his control. He would, therefore, ask the Speaker whether, if the House did not proceed any further with this matter that day, it could be raised again on the following day when Dr. Salter was in his place. If that were so, so far as the Government were concerned they would be prepared to move the adjournment of the motion till to-morrow.

The SPEAKER said that it was quite within the right of the right hon. gentleman to move that the debate be adjourned.

Mr. CHURCHILL accordingly moved the adjournment of the debate.

Mr. LLOYD GEORGE supported the motion of the Chancellor of the Exchequer. He said that he thought the Government had taken a very wise course. It was obviously very desirable that the hon. Member concerned should be present. There seemed to be some doubt whether Dr. Salter had received notice in time. It was undoubtedly a very serious charge to make against an assembly upon which so much depended. The repute of Parliament was not the inheritance of any particular party; it was important to the whole nation. Those who had any experience of these questions of privilege knew that on the whole it was very difficult procedure and the House did not always come out very well. He could not help thinking that Dr. Salter when he came face to face with the sentiment of the House—because it was a sentiment which was by no means confined to those who supported the Government, but was common to all parties in the House—he thought that the hon. Member would feel that not so much in his own interests as in the interests of the nation as a whole and the repute of such an important part of a constitution as the British Parliament it was desirable to withdraw the charge which might be only too readily taken up by those who did not know about Parliament. It was not true, and he was speaking as an old Member. Therefore, he sincerely hoped that opportunity would be taken to-morrow to clear up the situation and that it would not be necessary to proceed with Sir A. Holbrook's motion.

The debate was adjourned.

Outbreak of Infantile Paralysis.

Mr. AMMON asked the Minister of Health whether he would make a statement to the House as to the reported outbreak of infantile paralysis at Broadstairs and Leicester.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: An outbreak of infantile paralysis occurred in Broadstairs this month. Fifty-three cases have been notified and there have been two deaths. The outbreak has been mainly restricted to private boarding schools and day-schools in Broadstairs; three cases have occurred in convalescent homes. A medical officer of the Ministry visited Broadstairs immediately and has conferred with the medical officer of health and the local medical practitioners as to the administrative arrangements for dealing with the outbreak. He has also been available for consultation in regard to individual cases. All necessary precautions have been taken to control the epidemic, leaflets of advice have been issued, and facilities for hospital isolation and disinfection provided. The outbreak in Leicester began at the end of July and reached its maximum in the week ending Sept. 18th. The last case was notified on Oct. 14th. There were altogether 73 cases, six of which were fatal. They occurred sporadically, all over the town. In no instance did more than one case occur in a household and no one school was specially affected. Each case was personally investigated by the medical officer of health who arranged for the necessary isolation and for treatment, either at the isolation hospital or the Royal Infirmary.

Mr. AMMON asked whether instructions were issued from the Ministry of Health, so far as Broadstairs was concerned, that all reports were to be suppressed and no information allowed to leak out.

Sir KINGSLEY WOOD said that the Ministry were satisfied that there was no question of sleepy sickness involved. In regard to publication, all notifications had been published in the official returns week by week and he thought it was last week that the Council at Broadstairs—the proper body to make a statement—issued an official statement to the public generally.

TUESDAY, OCT. 26TH.

Dr. Salter's Charge against Members.

On the adjourned debate on Sir A. Holbrook's motion with reference to a speech delivered on Oct. 13th by Dr. Salter,

Dr. SALTER explained his absence on the previous day. He said that he was an official medical referee of one of the largest trade-unions in the country and he was engaged on *subpœna* in the courts giving medical evidence in workmen's compensation cases. His first knowledge that the matter was to be dealt with in the House was at 4.15 P.M., when a telegram signed "Holbrook" was handed to him as he stepped from the witness-box. The telegram had been sent to his house and his people had had some difficulty in finding him. On receiving the telegram he proceeded as fast as possible to the House and interviewed the Speake immediately on his arrival to explain the reason for hi absence. The speech to which exception has been take was delivered and reported over a fortnight ago, bu although the hon. Member who had raised this matter i the House found time to indicate his intentions to a news paper, he had not the courtesy or decency to inform hir till it was too late. With regard to the main speech and th indictment against him, he (Dr. Salter) had to say, speakin with a full sense of responsibility and regardless of any conse quences to himself, that he was not prepared to withdraw modify, or apologise for anything he had said on this matte He proposed to repeat the words which he had used an about which complaint had been made. At the same tim the House should certainly know the setting of the remark and the framework of the speech and not merely judge b two or three isolated sentences taken for sensational pres purposes from the context and published in that form The occasion on which the speech was delivered was tha of a small local temperance meeting of a body which wa celebrating its jubilee. He took occasion to make a historical review of the whole drink problem in this countr during the last 100 years, and he pointed out that th problem was a totally different one to-day from that whic confronted the founders of that Society. At that time gros and bestial drunkenness was common and even respectable and the phrase, "as drunk as a lord," indicated that th practice was conventional even among the upper circles o society. He pointed out that to-day they had got ri almost entirely of that bestial drunkenness which disfigure our social life in earlier days and that that change ha affected all ranks of society. Drunkenness to-day wa considered disreputable and something entirely improper i any person who held responsible public office. He the went on to point out that although that was the case i still remained the unfortunate fact that a certain pro portion of all classes in society—a small section, bu none the less sufficient to figure in statistics in the courts— could not drink a little without drinking too much and tha applied not merely to the poorer people, but even Member of that House were not exempt from that condemnation He went on to say—and he repeated it that day—that h had seen Members of all parties in the House—his own part he regretted to say included—drunk in the House, not o one occasion but on many occasions. (Cries of "Name." He was coming to the question of names.

The SPEAKER: I do hope the House will hear this matte quietly.

Dr. SALTER, continuing, said that when he said that h had seen such things he was making a statement which wa within the common knowledge of practically every Membe of the House, and it was a piece of affectation and hypocris for Members of the House to deny it. Since the matte was raised on the previous day from 50 to 60 Members a the very least had told him that they approved of wha he had said. They might not have agreed altogether wit the wisdom or propriety of making the utterance, or wit the particular way in which it was made, but they did nc contest the truth or accuracy of what he had said. H said further, that he had assisted other Members of th House to remove a hopelessly intoxicated Member from it precincts. That was known to Members on all side (Cries of "No.") It was common knowledge, and wa a smoking-room jest. He repeated, as he stated in the pres when he was tackled immediately after the speech, that h would do, the statement in the House in the presence c the persons who themselves were guilty. They mus have a proper sense of proportion in this matter. The could not take 600 men and women drawn from all socia grades, thrown together promiscuously, without finding certain number amongst them who unfortunately, if the took any drink at all, invariably were unable to save then selves from the disaster of taking too much. It was a mo unfortunate fact—a physiological fact—that the first effe of alcohol on some people at any rate was to remove a their powers of inhibition—all their powers of saying n That was the reason why he and a number of his colleagu in the House were personal abstainers for the sake of th weaker brethren in the House as well as outside. T number of such persons in the whole community w relatively small, and the number in the House was relative small; but no one could deny that they existed. He w in the 1922–23 Parliament and he saw more drunkenne then than he had seen in this Parliament. If it was a brea of privilege to criticise the action of certain Members wh he considered disgraced the House, degraded the Hous and lowered its tradition and its prestige by their action if that was a breach of privilege, let it be so. He had co mitted a breach of privilege and he could make no apolo therefor, whatever the consequence to himself might b He desired as earnestly and sincerely as anyone in t House to maintain the high prestige of the House and i authority in the country. He believed that the Parli mentary tradition alone would save the nation from ultima

disaster—industrial and economic. He desired to see the authority of Parliament increased rather than diminished, but he ventured to say with all respect that that end would be attained far more if certain Members of the House reformed their ways, and if they were given no support, such as would be given by voting for a resolution of this sort, and by attempting to intimidate and browbeat a few people who had taken on them the thankless and unpopular task of pointing these matters out. If the House desired to pursue the matter further and to appoint a Select Committee, or refer the matter to the Committee of Privileges, he would be prepared to go to that Committee and, painful ordeal though it would be, he would mention the individuals in each party whom he knew to be guilty in this regard, and he would take with him to that Committee a large galaxy of colleagues in the House who would be prepared to support his statement. He was entirely unrepentant with regard to what he had said.

The SPEAKER: The hon. Member must withdraw while the House proceeds with the debate.

Dr. SALTER thereupon withdrew from the Chamber.

Mr. BALDWIN, Prime Minister, said that he knew from his own experience that in all classes a steady and rapid growth of temperance, by which he meant the temperate use of alcohol, had taken place throughout the country. In an assembly like the House of Commons with 600 Members there must be some cases where Members forgot themselves temporarily. They all knew it, but they never spoke about it. What had hurt the feelings of the House was that one of their number who worked with them and shared their social life had thought it his duty to speak about these things outside and not to express regret to the House for having done so. He had no doubt that it was a libel upon the Members of the House and a breach of privilege. He would vote for the motion.

Mr. CLYNES suggested that it would be best to regard Dr. Salter's speech at best or worst as a well-intentioned vigorous effort at temperance propaganda and withdraw the motion.

Sir A. HOLBROOK said that he regretted that he could not see his way to withdraw the motion.

Mr. LEES-SMITH moved as an amendment that the matter be referred to a Committee of Privileges.

On a division the amendment was defeated by 247 votes to 95—majority against, 152.

The motion was then carried without a division.

CHELSEA CLINICAL SOCIETY.—The annual dinner of the society was held at the Café Royal, London, on Tuesday last, Dr. Ernest Young, the President, being in the chair. Well-selected speakers made the dinner an interesting as well as amusing occasion. Sir John Rose Bradford, proposing prosperity to the society and saying that its hospitable instincts were derived from the great Harvey's own precepts, pointed out that the connexion between Chelsea and clinical medicine was made particularly close by the association of Chelsea with Sir Hans Sloane, lord of the manor, physician, botanist, and archæologist. Dr. Young, in reply, said that in the case of the Chelsea Clinical Society, founded 30 years ago, its comparative youth accorded with its vigour, for they had this year to announce increased membership of the society, record attendances at the meetings, and success at the dinner gatherings. The health of the visitors was proposed by Mr. Ivor Back, who described Lord Carson as the terror of the inexpert expert witness; begged the Dean of St. Paul's to explain whether his name rhymed with "a jolly good binge" or with "let us dance and sing"; while to the third responder to the toast, Sir Arthur Conan Doyle, he addressed a moving reproach, in that the latest Sherlock Holmes adventure contained no mention of that sympathetic medical character, Dr. Watson. Lord Carson replied directly to Mr. Back's challenge, and, after testifying to his personal debt to medicine and his admiration of the medical profession, confessed that he liked that profession least of all in the witness-box, for, speaking as an advocate, he found the medical witness adamantine. Dean Inge told some humorous stories, and Sir Arthur Conan Doyle was thoroughly interesting in his reminiscences of the life of the unqualified assistant, which years ago he had led in the course of a strenuous apprenticeship to and career in the profession—a course which included volunteer military service, medical officership to a whaler, and the lease of consulting-rooms near Cavendish-square, where, he said, "I had a consulting-room and a waiting-room, but gave up the tenancy when both became waiting-rooms." The toast of the Allied Medical Societies, proposed by Dr. Seymour Price, was replied to by Sir James Berry, and Mr. Mortimer Woolf invited the company to drink to the health of their President with musical honours. During the evening Mr. Sterndale Bennett entertained the company with original songs, and especially with a reproduction of a Primrose League orator, asking a league meeting to withstand the attacks of Socialism, and trying to explain to them the annual balance-sheet.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Nov. 2nd.—5.30 P.M., ORTHOPÆDICS. (Cases at 5 P.M.) Mr. A. H. Todd: Ununited Fracture of Neck of Femur. Case for Diagnosis: Congenital Malformation of Right Upper Limb and of Left Eyelid. 8.30 P.M., PATHOLOGY.

WEDNESDAY.—5.30 P.M., TROPICAL DISEASES AND PARASITOLOGY. Communications: Dr. Aldo Castellani: Some Observations on Certain Cases of Chronic Colitis. Dr. T. W. M. Cameron: Some Biological Conceptions of Hydatid. Dr. R. J. Ortlepp: The Species of Nematode Genus Physaloptera in Man. Mr. S. Annecke: The Relative Numbers of Male and Female Gametocytes in Human Malaria (*P. falciparum*, *P. vivax*, *P. malariæ*), and Hæmoproteus in Birds. Dr. J. B. Christopherson: Further Observations on a Case of Actinomycosis. 8.30 P.M., SURGERY. Discussion: The Treatment of Œsophageal Carcinoma, to be opened by Mr. F. J. Steward, who will be followed by Mr. H. S. Souttar. Members of the Section of Laryngology are cordially invited to take part.

FRIDAY.—5 P.M., LARYNGOLOGY. Cases at 4 P.M. will be shown by Mr. Bell Tawse, Dr. Dan McKenzie, Mr. T. B. Layton, Mr. Norman Patterson, and others. Presidential Address: Dr. Andrew Wylie: References in Literature and Folk-lore to Rhinology and Laryngology. Communication (with cinematograph demonstration). Sir Charles Ballance and Mr. Lionel Colledge: Effects of Nerve Anastomosis on the Movements of the Vocal Cords and Diaphragm. OTOLOGY: Annual dinner, Langham Hotel, 7.45 P.M. Mr. G. J. Jenkins in the chair. 8.30 P.M., ANÆSTHETICS.

SATURDAY.—10.30 A.M. (Cases at 9.45 A.M.). OTOLOGY. Papers on Diseases of the Outer Ear will be read as follows: Introductory Remarks, by the President (Dr. Dan McKenzie). Common Affections of the Skin of the Outer Ear, by Dr. A. M. H. Gray. Intractable Dermatitis of the Pinna and External Auditory Meatus Secondary to Chronic Suppuration of the Middle Ear, by Mr. F. C. Ormerod. Paper: Mr. F. J. Cleminson: Deafness Associated with Fragilitas Ossium. Cases and specimens will be shown by Mr. Ormerod, Mr. Cleminson, Dr. Dan McKenzie, and Mr. Franklin. Epidiascopic Demonstration: Dr. J. S. Fraser: A Case of Congenital Deafness with Malformation of the Bony and Membranous Labyrinth on Both Sides.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

MONDAY, Nov. 1st.—5 P.M., Mr. C. E. Shattock: Scrotal Tumours.

THURSDAY.—5 P.M., Prof. Elliot Smith: The Significance of Anatomy. (Thomas Vicary Lecture.)

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

THURSDAY, Nov. 4tth—5 P.M., Dr. F. G. Crookshank: The Theory of Diagnosis. (Bradshaw Lecture.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Nov. 1st, to SATURDAY, Nov. 6th.—FELLOWSHIP OF MEDICINE. Special lecture at the Medical Society of London, 11, Chandos-street, W. Thursday, Nov. 4th, at 5 P.M., Mr. C. Max Page on Observations on the Treatment of Fractures. Free to all members of the medical profession.—ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, 234, Great Portland-street, W. Special afternoon demonstration in Clinical Surgery at 3 P.M. (Nov. 1st) by Mr. E. Laming Evans. Free to all members of the medical profession.—ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C. Special demonstration in Clinical Ophthalmology at 1 P.M. (Nov. 4th) by Mr. M. L. Hepburn. Free to all members of the medical profession.—HAMPSTEAD GENERAL HOSPITAL, Haverstock Hill, N.W. Practitioners' course in General Medicine and Surgery, 4.30 P.M. to 6 P.M. daily. Clinical demonstration followed by a lecture.—LONDON LOCK HOSPITAL, 91, Dean-street, W. Clinical work at the hospital each day from 1 P.M. onwards. Special lectures most afternoons. Further information from the Secretary of the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Nov. 1st.—2 P.M., Medical Cases in the Wards. 2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical Skin and Eye Clinics. Operations.

THURSDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

On Tuesday, Nov. 2nd, and Thursday, Nov. 4th, at 2.30 P.M., there will be special demonstrations of ear, nose, and throat cases and medical cases by Mr. W. Ibbotson and Dr. A. J. Whiting respectively.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, Nov. 1st.—10 A.M., Dr. Dowling: Skin Dept. 12 noon, Mr. Simmonds: Demonstration in Fractures and Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards.
TUESDAY.—10 A.M., Medical Registrar: Clinical Methods. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.
WEDNESDAY.—12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Mr. Tyrrell Gray: Operations. 2 P.M., Dr. Owen: Medical Out-patients.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. Bishop Harman: Eye Dept. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.
FRIDAY.—10 A.M., Sir Henry Simson: Gynæcological Operations. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. Operations, Medical and Surgical Out-patients, special Departments, daily 10 A.M. to 5 P.M., Saturdays 10 A.M. to 1 P.M.

POST-GRADUATE HOSTEL, Imperial Hotel, Russell-square, W.C.
MONDAY, Nov. 1st.—9 P.M., Sir James Dundas-Grant: Some Clinical Experiences.
FRIDAY.—9 P.M., Dr. E. I. Spriggs: Diverticulosis. Dinner 8 P.M. 5s.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street.
THURSDAY, Nov. 4th.—4 P.M., Dr. G. F. Still: The Urine in Childhood.

NATIONAL HOSPITAL, Queen-square, Bloomsbury, W.C.
MONDAY, Nov. 1st.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Risien Russell: Vertigo.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Hinds Howell: Muscular Atrophy.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Mr. Just: Intracranial Infection after Otitis Media.
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Bailey: The Electrical Reactions of Muscles.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Nov. 2nd.—5 P.M., Dr. Knowsley Sibley: Principles of Treatment. Local.
THURSDAY.—5 P.M., Dr. A. M. H. Gray: Eruptions Due to External Irritants.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Nov. 3rd.—4 P.M., Dr. H. M. Vernon: Ventilation in Relation to Health.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, Nov. 5th.—3.30 P.M., at the Royal Infirmary: Dr. Hallam: Demonstration of Some Common Skin Diseases.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSES.
TUESDAY, Nov. 2nd.—4.15 P.M., Dr. W. Dyson: Eczema in Relation to Sensitisation of the Skin.
FRIDAY.—4.15 P.M., Prof. R. B. Wild: Cancer of the Skin.

ANCOATS HOSPITAL POST-GRADUATE COURSE.
THURSDAY, Nov. 4th.—4.15 P.M., Mr. Harry Platt: Treatment of Common Injuries.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.
TUESDAY, Nov. 2nd.—4 P.M., Dr. R. Barclay Ness: Difficulties in the Clinical Diagnosis and Prognosis in the Various Forms of Chronic Bright's Disease. Discussion to be opened by Dr. C. E. Douglas.

Appointments.

BURNHAM, CECIL, M.B., Ch.B., F.R.C.S. Edin., has been appointed Surgeon to the Out-patients of the French Hospital.
COMPTON, A., M.D., D.Sc., Director of the Municipal Bacteriological and Chemical Laboratories, Alexandria.
Paddington Green Children's Hospital: YOUNG, J. M., M.B., B.Ch. New Zealand, House Physician; EVANS, J. P., M.R.C.S., L.R.C.P. Lond., House Surgeon.
Royal Halifax Infirmary: POLLARD, P.L., M.B., Ch.B. Manch., and HENRY, MC.W., F.R.C.S. Edin., Senior Honorary Surgeons; CLARK, T. L., M.D. Edin., and BOLTON, S., M.D. Edin., Assistant Honorary Surgeons.

Vacancies.

For further information refer to the advertisement columns.

Bethlem Royal Hospital, Lambeth-road, S.E.—Jun. Asst. P. £350.
Bradford Royal Infirmary.—H.S. £150.
Central London Ophthalmic Hospital, Judd-street, W.C.—Asst. Surg.
Central London Throat, Nose, and Ear Hospital. Gray's Inn-road, W.C.—Hon. Asst. Anæsth.
Coventry and Warwickshire Hospital, Coventry.—Res. H.S. £125.
Darlington County Borough.—Deputy M.O.H. £750.
Epsom Union.—M.O. and Public Vaccinator. £93 6*s.* 8*d.*
Essex, Administrative County of.—Asst. County M.O.H. £600.
Federated Malay States Medical Dept.—Radiologist. £700.
Freemason's Hospital and Nursing Home, 237, Fulham-road, Chelsea, S.W.—Res. M.O. At rate of £250.
Herefordshire General Hospital.—Hon. S.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Pathologist and Supt. £750. Also Asst. P.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Med. Reg. £100.
Hospital for Sick Children, Great Ormond-street, W.C.—Bio-Chemist. £600.
Hull Royal Infirmary.—Hon. Phys.
London, Female Lock Hospital, 283, Harrow-road, W.—Hon Obstet. S.
London, Homœopathic Hospital, Great Ormond-street, W.C.—Asst. P. for Dis. of Women.
London, Royal Free Hospital, School of Medicine for Women, Obstet. and Gyn. Unit.—Sen. Asst., £350. Also Third Asst. £270.
London, Temperance Hospital, Hampstead-road, N.W.—Hon. P. Also Clin. Asst. in Cas. Dept.
Manchester, Ancoats Hospital.—Anæsthetist. 10*s.* 6*d.* per attendance. Also Pathological Reg. £100.
Manchester Corporation, Public Health Dept.—Asst. M.O.H. (Maternity and Child Welfare). £850. Also Asst. M.O.H. £750.
Manor House Hospital, Golders Green, N.W.—Asst. S. £750.
Middleton-in-Wharfedale Sanatorium.—Sen. Asst. M.O. £600.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Asst. P. and two Asst. S.'s.
Newark Hospital and Dispensary.—Res. H.S. At rate of £200.
Northampton General Hospital.—Hon. S.
Northumberland, Wooley Sanatorium, near Hexham.—Med. Supt. £850.
Norwich, Norfolk and Norwich Hospital.—H.S. for Ear, Nose and Throat and Ophth. Dept. £120.
Royal Northern Hospital, Holloway, N.—M.O. to Out-patients. At rate of £125. Also H.S. At rate of £70.
St. George's Hospital, S.W.—Temp. Obstet. Reg. £40.
St. Mary's Hospital, W.—Phys. for Mental Diseases.
St. Mary's Hospital for Women and Children, Plaistow, E.—Res. M.O. and Asst. Res. M.O. At rate of £175 and £130 respectively.
St. Stephen's Hospital, 369, Fulham-road, S.W.—Third Asst. M.O. £300.
Sheffield Royal Hospital.—Ophth. H.S. £80.
Sheffield, Winter-street Hospital.—Jun. Asst. Tub. O. £359.
Throat Hospital, Golden-square, W.—H.S. At rate of £100.
West London Hospital, Hammersmith, W.—Phys.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Mere (Wiltshire), Newmilns (Ayrshire), and at Tilbury (Essex).

Births, Marriages, and Deaths.

BIRTHS.

EDWARDS.—On Oct. 18th, at Warwick House, Hemel Hempstead, the wife of Frank H. Edwards, F.R.C.S.E., of a son.
GRIFFITHS.—On Oct. 19th, at Farfield House, Kidderminster, the wife of P. Digby Griffiths, M.B. Camb., of a daughter.
SALISBURY.—On Oct. 21st, at 19, The Drive, Northampton, the wife of Walter Salisbury, M.S., M.D., F.R.C.S., of a daughter.

MARRIAGES.

O'SHAUGHNESSY—HUNTON.—On Oct. 3rd, at the Cathedral, Khartoum, Sudan, Laurence Frederick O'Shaughnessy, F.R.C.S. Eng., Sudan Medical Service, to Gwendolen Mary Hunton, M.B., B.S., C.M.S. Hospital, Omdurman, daughter of the late Frederick Hunton, M.D., of Sedgefield, County Durham.
PHILLIPS—NAISH.—On Oct. 23rd, at St. James's, Paddington, Sir John Phillips, M.D., J.P., to Beatrix Margaret, eldest daughter of the Rev. Francis Clement Naish, vicar of Upnor, Kent, and formerly vicar of Holy Trinity, Milton next-Gravesend.

DEATHS.

BOWES.—On Oct. 21st, at Greeba, Oxenden-square, Herne Bay, after a very short illness, Charles Kessick Bowes, M.A., M.D.
GRUGGEN.—On Oct. 19th, after a short illness, Dr. William Gruggen, M.O.H., of Durban-road, Watford.
HOLMES.—On Oct. 21st, at his residence, Wilbury-road, Hove, Colonel Thomas James Paul Holmes, M.B., L.R.C.S.I., R.A.M.C. (retd.), aged 81.
LLOYD.—On Oct. 23rd, at Tawelfan, Vale-street, Denbigh, N. Wales, David Lloyd, M.B., C.M. Glasg., J.P.
ROBINSON.—On Oct. 18th, at a nursing home, result of service, Captain George Cuthbert Robinson, M.R.C.S., L.R.C.P. Lond., R.A.M.C.
SCOTT.—On Oct. 24th, at his residence, Amherst-road, Ealing, Colonel Bertal Hopton Scott, C.M.G., M.B., B.Ch., A.M. (retd.).
SWANN.—On Oct. 25th, at a London nursing home, Mary Aelfreda St. Clair Swann, M.B., aged 27.
WILSON.—On Oct. 25th, at Bushey, Herts, Daniel Wilson, M.D.

*N.B.—A fee of 7*s.* 6*d.* is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Comments, and Abstracts.

RHEUMATIC DISEASE IN INDUSTRY.*

BY MATTHEW BURROW RAY, D.S.O., M.D. EDIN.,
HON. SEC., BRITISH COMMITTEE ON RHEUMATISM, INTERNATIONAL SOCIETY OF MEDICAL HYDROLOGY.

THE prevalence of rheumatic disease, both in this country and over Northern Europe generally, is a serious drain on the industrial resources of the countries concerned. The increased interest that is being taken in the problem of its prevention and arrest is largely due to the issue two years ago of the report on the Incidence of Rheumatic Diseases by the Ministry of Health, based on an inquiry made by 49 practitioners. Some striking figures in this report may be recalled. Each year some 370,000 insured persons seek advice for one or other form of rheumatic disease. In males these conditions are responsible for exactly one-sixth of the total sick absence from all causes. Nearly one-third of the male sick absence is due to non-articular rheumatism. Acute and subacute rheumatism only account for one-seventh. The sick absence in females amounts to one-seventh of the total from all causes. One-half of this is due to chronic joint disease, principally rheumatoid arthritis, which accounts for 30 per cent. One-seventh of the total sick benefit or nearly £2,000,000 is paid away annually to the insured population in respect of invalidity from these diseases and over 3,000,000 weeks of work are lost in consequence. This huge sum of money is not being spent in the provision of any treatment whatsoever; the allowance is for subsistence only.

What are the facilities at present available in this country for the treatment of this rheumatic population? The vast majority have to rely on what their ordinary medical attendant is able to give them. In the comparatively trivial cases it is no doubt enough, but there must remain a very large number who are not being adequately looked after. When we consider that the total number of beds available at the spa hospitals amounts to 681 and the annual number of patients treated for all diseases is 8606, of which 93 per cent. belong to the rheumatic group, we at once see that the supply does not come anywhere near the demand. Apart from the great spa hospitals there are no institutions where the insured rheumatic patient can obtain treatment of the kind likely to prove most beneficial. The physical treatment available at the out-patient departments of some of the larger hospitals hardly comes under this category.

Situation in Other European Countries.

Before considering how these defects can be remedied and what further facilities should be supplied, I will briefly summarise the situation as it exists in other European countries, based on reports presented to the conference on industrial rheumatism held last November.[1]

Holland.—There are no statistical official data to go on, but the number of rheumatic patients is very great. There are no spas and physical treatment is concentrated at the Central Institute for Physical Therapy in Amsterdam, of which Dr. J. van Breemen is director. Private patients who attend this Institute are mostly at a late stage of the disease and do not always finish their cure. Ten years ago panel patients were few in number, but now, under an agreement by which the sick funds guarantee rheumatic sufferers free treatment, nearly every panel patient who develops rheumatism comes to Dr. van Breemen in course of time. Every year he sees from 900–1000 patients with chronic rheumatic disease and another 1000 cases are sent to spas in other countries or treated at home. At the Institute general treatment with steam hot-air or electric light baths, douche massage, and mercury-vapour lamp is given for the improvement of the circulation, metabolism, and nervous system. These are found to have a favourable influence on local processes even without local treatment. To improve the functions of the joints fango, diathermy, local hot air and light baths, massage and exercises are employed. Dr. van Breemen pays a tribute to the extreme value of the Scottish douche in the treatment of what he describes as neuralgias of rheumatic origin. His general conclusions are as follows:—

1. For the better prevention of invalidity from rheumatic disease the wide application of physical treatment and baths is very necessary.
2. The study of the skin as an organ is a preliminary to the efficacious battle against rheumatism.
3. Spas should take measures to ensure the efficient treatment of panel patients.
4. In rheumatism the margin of safety in regard to rest and exercise is more limited than in the healthy subject.
5. Between the function of a joint and its pathological-anatomical condition there is often a great incongruity.
6. The establishment of clinics and laboratories for methodical research in rheumatism is greatly to be desired.
7. Every occupation has its own distinctive rheumatism.
8. The foundation of an international committee to bring more scientific and practical unity into the study and combating of rheumatic disease is essential.

Sweden.—There are no exact statistics of the incidence of rheumatic disease, but the available figures show that articular rheumatism ranks next to the infirmities of old age and above pulmonary tuberculosis in causing invalidity. Every year out of a population of 6,000,000 about 1500 persons are pensioned for articular rheumatism. As the disease is of long duration this entails great expense to the community.

Dr. G. Kahlmeter (Stockholm), consultant to the Direction des Pensions de Retraite, reports facilities for treatment as follows:—

The Spas.—Of these there are about 50 under private management, some of them centuries old, open only for about two and a half months in the year, and many of them not equipped to treat the different forms of disease. Prices vary, the cheapest rate being the equivalent of £10 for five weeks' treatment. The total number under treatment for all diseases is round about 30,000 each year, probably about 5000 being rheumatic cases.

Board of Pensions Institutions.—These are intended to prevent disabling—i.e., permanent pensioning. There are four in different parts of the country with 350 beds in all, compared with 681 beds available at the spa hospitals of Great Britain. They are directed by physicians, are open all the year, possess all the modern appliances for treatment, and are specially designed for the industrial classes. The course of treatment lasts two to three months; the patients get dental and orthopædic care, and, if necessary, are taught trades more suitable for their health. Two-thirds of the expense is borne by the State, the remaining third is paid by the patient himself or by the community to which he belongs if he is without means.

General Hospital Treatment.—This is practically confined to acute cases, very much as in this country. The Board of Pensions are, however, now building special departments in connexion with three of the largest hospitals for the treatment of arthritis and rheumatism.

Dr. Kahlmeter points out that they are still without what he regards as the most urgent thing—viz., a central arthritis hospital in Stockholm in close connexion with the university clinics. The Swedish committee for the combating of rheumatism is considering the provision of such a hospital.

Denmark.—There is no systematic movement for combating rheumatic affections. Among the 1,400,000 members of the authorised sick benefit club, which practically means the whole working-class of the country, 42,000 cases of rheumatism occur annually. There are no spas where gout and rheumatism can be treated, but six or seven private sanatoria use physical methods. Dr. Hans Jansen (Copenhagen), director of the Department of Physical Treatment, thinks there is a great need of more institutions of this kind and of others specially devoted to the treatment of rheumatic affections. For the total number of cases treated in 1923 was only about 3000: 1850 at the hospitals, 900 at private sanatoria, and 250 at the recently opened People's Sanatorium at Hald.

Switzerland.—There are, according to Dr. Frank Kornmann (Ragaz-Pfäffers), no available returns of cases of rheumatism and no systematic treatment. Insured members or members of sick benefit societies are treated according to opportunity, privately or as in-patients in cantonal hospitals or as out-patients at the chief hospitals or at the spas. At Ragaz all classes are treated and free board and lodging are available for those unable to pay. The treatment for chronic rheumatism includes protein therapy, X rays, movements, and physical treatment, especially by bath cures. When a specific ætiology is discoverable the corresponding specific treatment is added. The results are only partly recorded at out-patient clinics and at the spas. At the Geneva Polyclinic for Physical Treatment cases of chronic articular rheumatism form 30 per cent. of the total. It is worthy of note that 34 per cent. of rheumatic cases come from Geneva itself, 19 per cent. from the coast of the lake, 47 per cent. from the valleys of the Rhone and the Arve. The results of the Polyclinic in rheumatic cases show that slight and early cases are often entirely cured. The more chronic cases frequently show sufficient improvement to enable the patient to lead a normal or quasi-normal life and at any rate to avoid hospitalisation.

Roumania.—There is a general fund for social insurance under the Ministry of Labour. Insured working people who suffer from chronic rheumatism are treated at a marine sanatorium with 300 beds, where medicinal mud baths and other forms of hydrological treatment are available. The very poor people who do not come under the insurance scheme are treated in the Red Cross sanatoria, a certain number being sent to the marine sanatorium mentioned

* Based on a paper read before the Harrogate Medical Society.
[1] THE LANCET, 1925, ii., 1169.

above. Prof. A. Theohary informs us that increasing funds are now being allotted by public bodies in Roumania for the spa treatment of chronic affections among the poorer population.

France.—Sufferers from rheumatic complaints are treated at the thermal hospitals, the ordinary hospitals apparently admitting no rheumatic cases. Chronic cases are hospitalised in the asiles. Dr. Monod (Vichy) tells us that there is no national organisation for the treatment of these conditions and no statistics have been published.

The Need for Research.

Rheumatic disease, as van Breemen truly points out, is a clinical concept, not a disease picture; and, although an attempt to classify diseases of more or less unknown ætiology cannot lead to satisfactory results from the point of view of terminology, orderliness in description demands the adoption of some sort of temporary classification or tabulation. That proposed by the Ministry of Health meets the requirements. With the slow progress of knowledge whenever the ætiology of any member of this ill-defined group is thoroughly worked out, the terms rheumatic and rheumatism are dropped in relation to it. We no longer apply them to the various forms of infective arthritis; we should not speak of gonorrhœal or scarlatinal rheumatism. Chronic rheumatism is disappearing from our medical vocabulary. The difficulties of classification will solve themselves with the increase of knowledge consequent on more extended facilities for research.

No doubt there are great opportunities waiting for further victories in bacteriology and biochemistry; no research work can be considered worthy of the name that does not lay claim to their fullest activities. But there are other directions where research is needed—e.g., the influence of endocrine imbalance and the existence of a definite arthritic diathesis. Llewellyn has drawn attention to the close relationship that exists between certain forms of rheumatic disease and goitre. The association of arthritis with the climacteric is too well known to be dismissed as a coincidence. Climatic influences are still largely unexplained. Beyond the observation that a clay soil is "bad" for rheumatism there is not much on which to found an opinion as to what constitutes a "good" one. Certain dicta about the siting of houses and streets with regard to their elevation, aspect, hours of sunshine, proximity to the sea or to rivers, copied from one text-book to another, do not rest on a scientific foundation. No valid reason has been given in support of the popular idea that marine stations are unsuitable places of residence for rheumatic subjects.

The nebulous state of our ideas on these and many kindred questions is undoubtedly due to the insufficiency of our knowledge of the functions of the skin as a protecting agent and the main channel through which the resistance of the body is maintained. When we consider that one-third of the entire blood-supply of the body is capable of being contained at one time in the cutaneous circulation, the importance of further research into the physiology of this organ is at once evident.

Certain trades are more prone to the incidence of rheumatic disease than others. Trustworthy data on this point can only be obtained from careful investigation of large numbers of workers in the various trades. Not only the workers themselves but the conditions under which they are employed must be carefully gone into. How far van Breemen's saying that every trade has its own particular variety of rheumatic disease is true in this country we do not know, and our ignorance indicates a possible line of fruitful inquiry.

Research on the lines thus briefly indicated has been impracticable for the reason that the material is not readily available. Where are the majority of the cases to be found? The more severe types, chiefly in their early stages, are scattered in twos and threes throughout the general hospitals, where they are in most instances thoroughly investigated from every side—bacteriological, biochemical, radiological, dental, and cardiological. But there is no statistical correlation of such cases and much valuable work is wasted. The more advanced and practically bed-ridden cases are to be found mainly in the Poor-law infirmaries where ample opportunities for the study of end-results are available, but this study is more depressing than valuable, especially if there is nothing else to see. The less serious cases, most of those for which much can be done, are found frequenting the surgeries of insurance practitioners at stated intervals to renew their certificates of disability. No one probably realises more fully than the medical attendant the hopelessness of doing any permanent good to these people without recourse to physical methods of treatment. He is aware of the necessity of highly specialised investigation. But where is he to obtain it? He does the best he can by trying to secure admission for them to one or other of the spa hospitals. Unfortunately, however, the less obvious and permanent the disability, the smaller the chance of securing admission thereto. Apart, therefore, from the Poor-law institutions the only places where cases are collected and available for thorough clinical research are the spa hospitals and here also the end-results are in a depressing proportion.

The remedy for this unsatisfactory state of affairs must afford the maximum amount of service with the minimum amount of expenditure of energy. To begin with, the cases must be collected and then sorted. To commence with, a central clearing house should be provided to which all cases would be recommended by their insurance doctors. Such an institution would form a regular "arthritis unit" with medical director and staff of specialist investigators. Every case sent to the unit would be submitted to investigation, not only bacteriological and biochemical, but on the lines I have briefly sketched out. Careful records would be kept. The unit would decide the future disposal of the case. It might be deemed necessary to keep one case for special observation, another might be instructed to attend at certain times, while a third would possibly be sent to one or other of the spa hospitals.

The first effect of all this would be to prevent the spa hospitals being crowded with unsuitable cases and thus to increase the accommodation for hopeful cases. There would also be a concentration of clinical material out of which a selection of suitable patients for further investigation could easily be made. As such investigations necessarily include inquiries into home and work surroundings, family histories, and the like, the services of non-medical voluntary workers would be enlisted. Research would then proceed on two parallel lines: individual as regards the case immediately under observation, and general as regards the accumulation of data eventually to form the basis for statistical information. As time went on these units or clinics would have to be multiplied and established in all large centres of population. Rheumatic disease is just as prevalent in rural as in urban districts and this difficulty must be faced in any comprehensive scheme by providing lodging accommodation in the neighbourhood of the unit, or by the establishment of hostels, the former being the cheaper to begin with.

Provision of Treatment in Large Towns.

The supply of adequate treatment for the insured rheumatic population is being carefully considered by a committee of the International Society of Medical Hydrology, which has suggested the establishment in all large centres of population of institutions where the services of medical teams will be available. Such a team would consist of a physician (acting as director), a surgeon, a dentist, a radiologist, a throat specialist, a bacteriologist, and a bio-chemist. In-patient treatment would only be required for cases needing special observation and for those who for any reason could not attend as out-patients. Treatment would include vaccine therapy, dental, surgical, and orthopædic treatment as well as measures for the relief of pain, for allaying, for rendering stiff tissues supple, for increasing absorption, and for re-educating muscles. Such measures would comprise saline and aerated baths, whirlpool baths, vapour baths, both local and general, packs of peat, mustard and fango massage, and manipulative douches. The general effect of the various forms of treatment would be the subject of research and careful records and measurements would be made. Inquiry into the comparative value of various kinds of treatment is only possible when large numbers of patients are being dealt with, and the scheme assumes that these units would act as a much-needed stimulus to the serious study and practice of physico-therapy.

Increased Facilities for Treatment at the Spas.

A scheme for dealing with insured rheumatic patients has been formulated by the British Spa Federation, under which treatment is offered either free or at greatly reduced rates. The scheme deals mainly with the class of case which does not require bed treatment or nursing. Accommodation for these cases should be found in hostels established either by the Ministry of Health, the friendly societies, or some local committee; in the initial stage the cheaper and easier course might be taken of providing approved lodgings. For patients requiring bed treatment and nursing, admission to the local mineral water hospital is suggested. In the view of the subcommittee patients should not be certified for spa treatment by their panel doctors, but should pass through one or other of the arthritis units or clinics where their future disposal would be decided after a thorough investigation of their condition. This would ensure the fullest advantage being taken of the available accommodation and unsuitable cases would not find their way to spas to the detriment of others more likely to benefit. The federation estimates that taking the spas as a whole 1500 patients could be under treatment at any one time; this would amount in round figures to close on 20,000 for nine months of the year, allowing a three weeks' stay for each case. Patients should attend at a central place where they would be seen at certain times by those medical men who elect to undertake this work, medical attendance and remuneration being on a sessional basis.

ANOTHER ACTION FOR WRONGFUL CERTIFICATION.

POSTLETHWAITE *v.* PHIPPS AND PRECOX.

UNDER the auspices of the Listerian Society a mock trial was held before the Right Hon. the Lord Chancellor (Lord Cave) and a special jury, of which Lord Hambleden was foreman, at King's College Hospital Medical School, on Wednesday, Oct. 20th. The following members of the society took part: Dr. John Wood (Oswald Postlethwaite), Miss C. Gibson (Lottie Postlethwaite), Dr. R. L. Quilliam (Dr. Sigmund Waterman), Dr. E. B. Strauss (Dr. Dementius Precox), E. N. Butler (Dr. Phipps), and Miss M. McHugh (Flora Macdonald).
